The first business was the reading of the paper on "Franchises for Quasi-Public Corporations,"[2] by Mr. **Allen R. Foote**.

In the discussion which followed, **Judge Armstrong** believed there was no reason why one electric light company should not furnish all the electric light needed in a given city; but they are so constituted that, just so sure as that was the case, notwithstanding the fact that the company might be under government supervision, and its affairs open to inspection at all times, there would always be the question raised whether it could not be better done under this, that or the other circumstances. They were anxious to furnish at the cheapest possible price this form of city lighting which had become a necessity and so great a factor in our modern civilization; they were willing and anxious to make the cost of production less and receive only a fair profit, and give the service to the people as cheaply as they could. When they could get the people to properly understand this question from a commercial standpoint, there would be no difficulty in obtaining renewals of franchises, so that they would be practically perpetual, and the advantages set forth by Mr. Foote's plan would be gained in that way; but it could not be done by government work, by law, but by the education of the people.

Mr. C. R. Scott agreed with Judge Armstrong that people had to be educated to a true realization of the position of electric lighting companies. Once their position is properly understood, they would have no difficulty in holding their position; they would be like the Bell Telephone Company when its patent expires, it will keep its customers. If electric light companies give to their customers the best article obtainable at a reasonable price, they will be able to go right on ; there will be no danger of anybody else coming in, for there was not enough margin of profit in it.

The paper by Richard Hammond on "How to Fire a Steam Boiler"[3] was then read.

In the discussion which followed, **Mr. D. Ashworth** touched upon the fact that people had for a long time drifted into the idea that any one is capable of being a fireman; but he considered it a matter of great importance to get the best firemen and to select them with as much care as one would an engineer.

Mr. J. B. Edson agreed with Mr. Ashworth in the necessity of having intelligent firemen, and also thought that in their attempts to improve the steam engine engineers had neglected the boiler. He thought that a slight advance in pay over commercial rates, which are considered sufficient for that kind of low brute force, would often be productive of good results. On the steamship City of New York they have some intermediate dampers near the stoke-hole door, and this shuts off each furnace before the door is opened; thus preventing any ingress of cold air. He thought there should be some way found to avoid opening the doors of any furnace; it was wrong to do it, and have a continued contact of the hot with the cold air, which certainly affects combustion considerably. The rapidity with which a door is opened and closed was very important.

Mr. J. A. Seely believed there was a large field for an intelligent lot of men to follow the occupation of firemen. He paid his firemen a very good salary; and he had been so successful in the economies of his work that he proposed to raise their salary.

In answer to a question by **Mr. Coggshall**, **Mr. Hammond** stated that a depth of six inches of fuel gave the best results with either hard or soft coal.

Mr E. F. Peck stated that formerly they paid $1.75 a day to their firemen, and expected them to work twelve hours a day, every day in the year, without vacation. They now pay them $2.25 a day, and give them a week's vacation in the summer. In looking over their records he finds that where they were using $2\frac{75}{100}$ lbs. of coal per hour per lamp, they were now using $2\frac{51}{100}$ lbs. He believed that the additional wages had brought about this result.

Mr. C. J. Field remarked that in a station built by him the draft of each furnace could be separately controlled.

Judge Armstrong suggested that it might be a good plan for the Association to organize a bureau of firing.

Judge Armstrong then offered the following resolution :

> *Resolved*: That the National Electrical Light Association cordially endorses the plan of holding World's Congresses at the Columbian Exposition, and pledges its hearty co-operation to make the Electrical Congress under such auspices a success.

The resolution was carried.

Mr. E. F. Peck then read a paper entitled, "Overhead Construction."[4]

---

[1] See p. 223.

[2] See p. 227.

[3] See p. 226.

[4] See p. 219.

In the discussion which followed Prof. Thomson thought that if we had our wires well planned, if they were kept from an appearance of straggling and uncertainty of direction, the public would like and appreciate a good overhead construction as much as they might an underground. It is true that it would be desirable to get the poles out of the way; but an underground system means certain difficulties and large expenses which must be paid for by the user. The chief difficulty was that the lineman is instructed to go and string up as soon as he can to light somebody's premises; he is in charge of the whole thing, and he is not always instructed in his business, and perhaps has had his training in the hanging of telephone wires. Prof. Thomson did not agree with Mr. Peck that a joint covered with tin foil was as good as a soldered joint. The tin foil might possibly keep the elements of corrosion away from the bright wire, but it did not take the place of a soldered joint.

Mr. J. A. Seely thought there was only one way of making a joint, and that was by twisting it with some kind of a sleeve. He had tried tin-foil, and found in using it that the linemen are not careful with it; after it is put around the wire, in taping it, it is often abraded, which opens the seams of the foil. He usually soldered the joints and covered them with a rubber liquid.

Mr. Peck stated that he did not mean to have it understood that he recommended a foil-wrapped joint. He simply spoke of it as one method of making a joint, when it was not easy to solder, and especially where the work had to be done in a great hurry. The tin-foil protects the joint from the effect of the rubber and is better than a plain joint.

Mr. Seely stated that he believed it was entirely a mistake to erect large poles. He thought it had been thoroughly demonstrated in the past year by the Long Distance Teléphone Company that they are failures. An eighty-foot pole is liable to break in heavy storms in winter, and surely they were carrying more weight with a copper wire on a pole than the small No. 12 wire used on telephone poles. The average pole should not exceed 50 feet in height. He saw very little use in protecting poles in the earth with any substance whatever; it was an expensive luxury.

Mr. Peck said he did not recommend high poles, and did not believe in them. That was a point that each central station man must settle for himself. In Brooklyn they were obliged to run their main lines over a street which had an elevated railway structure, and with a number of stations all along the line, which they had to jump over, and it was necessary to use a high pole. On all other lines they used a pole from 35 to 50 feet. He liked a pole about 40 feet high.

Mr. Wightman inquired as to the method of locating an open circuit on the line.

Mr. Peck replied that they had no system any more than the ordinary method with the magneto-bell. At night-time their inspectors use jumpers. He knew of no invention practicable for locating open circuits.

Mr. M. D. Law said his system was to use an arc light machine on independent power, which could be run at slow speed, or preferably to provide a special small dynamo for this purpose. In the location of grounds on all arc light circuits he used a bank of 50 to 52 volt incandescent lamps in series, using about five more lamps than the lamp capacity for the dynamos. These lamps are coupled in series, with the wire leading from each lamp to a switch, so that it may be moved to cut out 1, 2, 3, 10, 25 or 50 lamps as the case may be. By connecting one side of this lamp bank to the circuit, say the positive side, and the other side of the lamp bank to ground, one will either have the lamps burning at full candle power or perhaps not showing anything. Then by turning on or off the lamps until they are brought to their proper potential or candle power, the location of the break can be located within one or two lamps.

Mr. Wm. Stanley, Jr., said he had had occasion to look into the matter a little, and as a conclusion had found that it would not be remunerative to put wires underground until a system had been found which would displace 20 wires above ground for one underground; that meant that in the case of an arc light circuit, one would have to put 20 times as many arc lights on one circuit by some means unknown at present.

Mr. J. E. Lockwood deprecated the use of the dynamo to locate open currents, as suggested by Mr. Law, on account of its danger to the men. He believed the magneto-bell answers the purpose fairly well. If it is done with a dynamo the order should be imperative to the man in charge of starting the dynamos, that the man sent out to locate the break is the only man to give the word to start.

Mr. Law stated that during ten years' use of his methodnot a single accident had occurred.

Mr. E. A. Leslie then referred to the self-induction of overhead wires, particularly when not strung on the poles in such manner as to neutralize each other, and quoted a number of tests recently made on his lines in New York showing that in the case where a proper arrangement of the wires on the poles had been neglected, the apparent resistance of the circuit was 60 per cent. higher than in the case where this matter had received attention.

The paper on "Operation of High Tension Currents Underground,"[1] by Mr. E. A. Leslie, was then read; also the paper on "The Underground Construction of the Buffalo Railway Company,"[1] by Mr. J. B. Craven.

Judge Armstrong believed that the companies gained all the practical advantage possible under the present overhead systems and it was only a question for the public whether they would put an enormous sum of money into these subways—for it is the consumer that must pay for them—or whether they would put it in their pockets.

Mr. W. H. Brown gave a short account of the history of the New York subways. At present, on Third avenue, there are 20 ducts built for a distance of 12 miles, from the City Hall to the Harlem River; and there are probably not four occupied for the whole distance, and at no place more than 11. This is true to a great extent of the electric light wire subways; the fact being that only forty-five per cent. are now occupied the commission having designed to build for future needs. There was no doubt as to the great advantage of the underground system, and he firmly believed that in the future the necessities of the case would demand underground electric communication and power transmission.

Mr. F. W. Cushing thought that a simple wooden pump log had been found equal to, or better than, most of the more expensive conduits. The ideal conduit, of course, was a subway in its true sense; that is an arch or tunnel built under the street, large enough to walk through.

On motion of Mr. Seely the meeting adjourned until 3.30 p. m.

THURSDAY AFTERNOON MEETING.

Judge Armstrong offered the following resolution:

> *Resolved*, That the members of the National Electric Light Association extend their hearty thanks to the Bell Telephone Company, of Buffalo, and the American Telephone and Telegraph Company, of New York, and the Postal Telegraph and Cable Company for their very great kindness and courtsey in extending to us the free use of their wires; privileges of which we have shown our appreciation by a very general use, and which have helped greatly to the enjoyment of our very pleasant stay in the city of Buffalo. To our President, and the citizens of Buffalo, who have so hospitably treated us, we desire to extend our hearty thanks. We close this convention with the firm conviction that it has been the most successful one in our history.

The resolution was adopted amid applause.

The Association then went into executive session.

The following officers were elected for the ensuing year: *President*, James I. Ayer, St. Louis, Mo.; *First Vice-President*, E. A. Armstrong, Camden, N. J.; *Second Vice-President*, C. H. Wilmerding, Chicago, Ill.; *Secretary*, George F. Porter, New York; *Executive Committee* (new members), H. H. Fairbanks, Robert MacKie, C. Lee Abell; (old members), John A. Seely, E. F. Peck, Chas. R. Faben, Jr., Frederic Nicholls, M. D. Law, A. M. Young.

The next meeting of the Association will be held in St. Louis, Mo., February, 1893.

LIST OF ATTENDANTS AT THE BUFFALO CONVENTION.

New York City.—P. C. Ackerman, E. P. Atkinson, P. H. Alexander, W. M. Andres, Louis R. Alberger, Frank Ball, Jos. Barre, E. E. Bartlett, G. W. Blake, S. S. Bogart, W. H. Brown, A. S. Brown, A. G. Brown, J. Stanford Brown, E. Caldwell, Capt. W. L. Candee, F. R. Chinnock, L. F. Collins, S. L. Coles, F. R. Colvin, R. B Corey, W. F. Cullen, F. S. De Ronde, A. E. Davis, F. Darlington, Jarvis B. Edson, W. H. Eckert, H. A. Foster, C. G. Ferguson, C. J. Field, E. A. Fitzgerald, J. W. Godfrey, L. H. Hart, A. E. Hall, O. H. Hewlett, W. A. Hubbard, S. W. Hume, G. W. Hunt, W. T. Hunt, H. G. Issertel, W. J. Johnston, E. F. Kendall, J. C. Knight, A. A. Knudson, A. B. Laurence, H. Ward Leonard, E. A. Leslie, C. P. MacKie, George T. Manson, T. C. Martin, D. B. McCay, W. R. McLaughlin, G. S. Melville, Augustus Noll, W. F. Osborn, G. M. Phelps, H. W. Pool, George F. Porter, J. C. Pierrez, R. W. Pope, Isaac M. Post, H. N. Powers, H. L. Richards, S. Rosentamm, C. A. Schieren, C. A. Schieren, Jr., John A. Seely, E. W. Seymour, R. H. Sherwood, H. L. Shippy, Chas. D. Shain, Robert J. Sheehy, H. J. Smith, T. J. Smith, F. H. Sparling, M. C. Sullivan, H. M. Swetland, T. R. Taltavall, J. B. Taltavall, S. F. Taylor, W. H. Temple, C. S. Van Nuis, P. H. Van der Weyde, N. D. Webster, Benjamin R. Western, Jos. Wetzler, S. S. Wheeler, H. C. Whitney, G. L. Wiley, Erastus Wiman, E. E. Wood, W. H. Woods, G. F. Porter.

Akron, Ohio.—F. H. Bostwick, C. J. Butler, W. D. Chapman.

Baltimore, Md.—E. Carl Breithaupt, E. E. Ries, W. S. Horry, Henry Wiegand.

Boston.—C. E. Bibber, Capt. Wm. Brophy, H. S. Chase, C. C. Chesley, J. W. Cowles, Thos. Cooper, W. A. Daverin, L. S. Dumoulin, Paul G. Fielder, C. S. Haley, F. T. G. Hill, Welles E. Holmes, P. H. Hover, C. W. Houghton, J. H. Mason, Louis McCarthy, Cecil W. Mackenzie, Frank Ridlon, E. L. Ross, E. P. Sharp, Geo. R. Stetson, J. B. Smith, S. S. Sherman, N. V. Titus, D. T. Urquhart, W. F. Walker, W. L, Walker, C. A. White.

Buffalo.—C. Lee Abell, Frank W. Abbott, G. A. Burnett, A. A. Berrick, P. P. Beals, J. Bower, W. A. Chaffee, C. H. Darcy, W. A. Fenn, T. C. Frenyear, Dr. W. H. Heath, F. C. Hoddick, J. A. Hutchinson, W. S. Howard, C. R. Huntley, W. C. Jaynes, F. P. Jones, Frank Kitton, F. P. Liittle, A. W. Lockwood, H. McMann, H. B. Oakman, J. L. Osgood, A. B. Penfield, T. F. Reynolds, A. P. Roberts, Chas. Slosson, J. B. Slocum, P. K. Stern, A. C. Terry, J. W. Tillinghast, David Tucker, Geo. J. Urban, Jr., A. B. Weaver, W. T. Wilson.

Bradford, Pa.—J. H. Rose.

Bridgeport Conn.—W. C. Bryant, J. M. Orford.

Bristol, Pa.—Chas. E. Scott.

Brooklyn, N. Y.—T. E. Crossman, C. H. Faye, Jas. Ferguson, C. J. Foyle, E. F. Peck.

Camden, N. J.—Hon. E. A. Armstrong, John H. Bentley.

Canton, Ohio.—W. A. Lynch, H. M. Lyman.

Canandaigua, N. Y.—C. J. Purdy.

---

[1] See p. 215.

[1] See p. 218.

Cincinnati, Ohio.—Chas. E. Jones, Luke Lilley, Robt. MacKie.

Chicago.—Wm. S. Armour, John I. Beggs, A. H. Bauer, E. L. Bunnell. W. F. Collins, C. D. Crandall, George Cutter, Elisha Gray. L. A. Gray, Edw. Ellicott, T. J. Lovett. W. W. Low, H. P. Lucas, G. G. McDuff, J. B. O'Hara, W. B. Pearson, Frank B. Platt, E. T. Powers, J. H. Shay, C. T. Waugh, C. H. Wilmerding.

Cleveland, Ohio.—J. B. Crouse, S. S. Leonard, Benj. F. Miles, I. R. Prentiss, J. D. Prentis, Fred. Scheffler.

Cuyahoga Falls, Ohio.—E. L. Babcock.

Des Moines, Iowa.—J. A. Colby.

Danbury, Conn.—E. T. Wightman.

Dayton, Ohio.—W. H. Ashton.

Detroit, Mich.—O. D. Chase, Geo. E. Fisher, F. E. Fisher, Chas. D. Jenney, J. E. Lockwood, W. H. Spicer, B. R. Van Court, H. L. Wilton.

Erie, Pa.—E. D. Curtis, A. L. Daniels, W. N. Lovell, Jas. McBrier, N. S. Possons, C. J. Sturgeon.

Fitchburg, Mass.—H. F. Coggshall.

Goldenburg, Neb.—B. Olip.

Hartford, Conn.—Chas. J. Hills, E. B. Hatch, C. E. Newton, A. H. Pease, C. L. Tolles.

Herkimer, N. Y.—John Kelley.

Houghton, Mich.—Jas. R. Dee.

Huron, Mich.—V. J. Stephenson.

Indiana, Pa.—S. M. Wheeler.

Indian Orchard, Mass.—E. L. Ross.

Jersey City, N. J.—Chas. A. Learned.

Lancaster, N. Y.—W. H. Boulton, C. V. Doty, R. J. Getz, W. C. Hodge, W. F. Holloway, F. P. Vandenbergh.

Little Falls, N. Y.—G. M. Lee.

Lockport. N. Y.—Chas. R. Bishop, I. H. Babcock, H. J. Fenton, H. J. Fulton.

London, Ont.—Chas. Goble, Chas. B. Hunt.

Lynn, Mass.—Elihu Thomson, Caryl D. Haskins.

Medina, N. Y.—W. R. Cunz.

Memphis, Tenn.—Wm. O'Hearn.

Minneapolis, Minn.—A. M. Robertson.

Montreal.—A. J. Corriveau, A. O. Hunt, David A. Starr.

Morristown, N. J.—F. J. Anderson.

Newark, N. J.—C. O. Baker, Jr., R. O. Heinrich, C. H. McIntire.

New Bedford, Mass.—Chas R. Price.

New Britain, Conn.—L. C. Whitney.

New Brunswick, N. J.—A. J. Jones.

New Haven.—C. D. Warner.

Newton, Mass.—W. C. Holmes.

Niagara Falls.—C. M. Morse, F. E. Pritchard, Benj. Rhodes.

North East, Pa.—J. R. Phillips.

Ogdensburgh, N. Y.—J. H. Findlay.

Owen Sound, Ore.—Jno. Parker.

Ottawa, Can.—W. F. Soper.

Penn Yan, N. Y.—W. Stanley Bruen.

Philadelphia, Pa.—A. Balsley, A. E. Braddell, Dr. W. H. Busk, C. H. Clay, H. A. Cleverly, H. B Cutter, A J. De amp, W. N. Famous, J. A. Hanna, Carl Hering, F. A. La Roche, C. M. McIntire, J. K. Martin, A. H. Manwaren, H. T. Paiste, Geo. E. Peifer, G. W. Vallee, Wm. H. Weston, E. G. Willyoung, E. W. Wilkins.

Pittsburgh. Pa.—Dan. Ashworth, N. H. Byam, Maurice Coster, G. T. Evans, Morris W. Mead, H. Robbins, L. B. Stillwell, Calvert Townley, G. A. Blaxter,

Pittsfield, Mass.—Chas. Atwater, C. C, Chesney, R. Fessenden, Henry Hines, John W. Noble, Wm. Stanley, Jr., W. A. Whittlesey, W. A. Whitney.

Poughkeepsie, N. Y.—J. N. Candee, Jas. B. Platt.

Port Huron, Mich.—J. W. Smith, D. J. Stephenson.

Providence, R. I.—Marsden J. Perry.

Pueblo, Cal.—E. M. Reed.

Ravenna, Ohio.—Chas. L. Rodman.

Reading, Pa.—J. L. Boyer.

Rockford, Ill.—W. B. Roberts.

Rochester, N. Y.—J. A. Almstead, J. G. Kaelber, Edgar A. Gay, C. B. Griffith, J. E. Putnam, G. A. Redman.

Rutland, Vt.—M. J. Francisco.

Sagamon, Mich.—G. A. Gilbert.

Schenectady, N. Y.—M. D. Law, F. A. Stevenson.

Seneca Falls, N. Y.—R. H. Aldrich, S. S. Phillips.

Sewickley, Pa.—E. P. Young.

Springfield, Ill.—A. L. Ide.

Salem, Ohio.—Geo. A. Barnard, D. L. Davis.

St. Louis, Mo.—Jas. I. Ayer, J. H. Rhotehamel, E. Ruebel, A. Wolfram.

Steubenville, Ohio.—J. Gwynn.

Syracuse, N. Y.—Thos. H. Fearey, E. P. Doen, F. M. Hawkins, C. F. Hayes, H. J. Gorke, J. D. McIntyre, James Pass, S. H. Riker, A. P. Seymour, F. J. Wright, F. H. Leonard.

Summit, N. J.—W. E. Doying.

Telluride, Col.—P. N. Nunn.

Tolland, Conn.—F. H. Underwood.

Toronto, Can.—Frederic Nicholls, W. J. Morrison, H. D. Thornberry, H. S. Thornberry.

Trenton, N. J.—J. T. Ridgeway, Richard K. Whitehead, Cresent Ins. Wire and Cable Co.

Utica, N. Y.—W. F. Bossart, M. G. Brayton.

Waltham, Mass.—J. T. F. Hill.

Waterbury, Conn.—D. L. Hungerford.

Warren, Ohio.—E. Metzger, W. D. Packard.

Warsaw, N. Y.—C. E. Fargo.

Washington C. H., Ohio.—Jerome Penn.

Washington, D. C.—Allen R. Foote, Fred. W. Royce, J. N. James.

Worcester, Mass.—H. H. Fairbanks.

Windsor, Conn.—M. E. Baird, A. D. Newton.

Wilmington, Del.—Frank D. Sweeten, C. R. Van Trump.

Ladies.—Miss E. W. Armstrong, Camden, N. J.; Mrs. Jos. Barre, New York; Mrs. C. O. Baker, Jr., Newark, N. Y.; Mrs. James Ferguson, Brooklyn; Mrs. M. J. Francisco, Rutland, Vt.,; Mrs. W. J. Johnston, New York,; Mrs. M. D Law, Schenectady, N Y.; Mrs. F. H. Leonard, Syracuse; Mrs. C. M. Morse, Buffalo; Mrs W. D. Packard, Warren, O.; Mrs. G. A. Redman, Rochester; Miss Redman, Rochester; Miss A. E. Redman, Rochester; Mrs. Frank Ridlon, Boston; Mrs. E. L. Ross, Indian Orchard, Mass.; Mrs. S. S. Sherman, Boston; Miss M. L. Shivers; Mrs. T. J. Smith, New York; Mrs. T. J. Smith, New York; Mrs. N. V. Titus, Boston; Mrs. Schuyler S. Wheeler, New York; Mrs. E. A. Willyoung, Philadelphia.

CONVENTION EPISODES.

On Tuesday evening President Huntley and Mr. George Urban, Jr., entertained a select party of guests at the Buffalo Club, including Prof. Elihu Thomson and Messrs. Wilmerding, Ayer, Wilder, Candee, Baker, as well as a number of leading Buffalo citizens. A most delightful time was spent, and supper was followed by several interesting and witty speeches. It was 4 a. m. before the party broke up.

The Association has reason to congratulate itself upon the active participation in its work of such distinguished electricians and inventors as Prof. Elihu Thomson, Dr. Elisha Gray and William Stanley, Jr. The cheers proposed to Prof. Thomson by Mr. Stanley at the banquet, were given by the gathering with tremendous enthusiasm; while the presence of Dr. Gray and his happy, off-hand speech closing the dinner will long be remembered as a leading event of the Buffalo Convention.

The arrangements made by Mr. C. O. Baker, Jr., for the Electric Special from New York on Monday proved most satisfactory. The train started at 11 a. m. and consisted of six cars, including dining and buffet smoker. The pleasure of the trip was added to by the performances of a mandolin band, and the taking of group photographs at Albany and Utica. At Albany, the Boston contingent, under the care of Mr. A. C. Shaw was picked up. At Rochester the train was met by an advance guard from Buffalo, headed by President Huntley.

Never did a President of the Association devote himself more assiduously to the manifold duties of host, than Mr. Huntley, and he was most ably backed up by such men as Messrs. George Urban, Jr., C. Lee Abell, H. B. Oakman, F. P. Little, R. J. Getz, Daniel O'Day, F. V. Doty, W. G. Case, W. A. Fenn, to one and all of whom, as to many others, the members of the Convention are under many obligations for thoughtful attentions and lavish kindnesses. Much credit is due to the various committees and executive officers for their well-laid plans, as the result of which everything went off without a hitch.

One of the most delightful episodes of the week was the reception given on Tuesday evening by Messrs. Candee and Manson in the Okonite parlors, which were crowded not only by the delegates but by ladies. With a felicity that has been shown more than once, the hosts had provided a special form of entertainment, being nothing less than a series of monologues and recitations by the inimitable Marshall P. Wilder, who was never in better vein, and who kept his audience in convulsions of laughter. Refreshments were provided, and several musical members assisted with songs and piano solos. By unanimous and overwhelming request, the conversazione was repeated on Wednesday evening.

Considerable pleasure was afforded to a large number of delegates by the opportunity to visit and inspect the fine plant of the Buffalo Street Railway Co. On Thursday afternoon a special trip over the road was organized by Mr. C. J. Field, of the Field Engineering Co., which did all the work on track, line and power-house, and three or four hours were spent most profitably. The inspection of the power-house was quite prolonged, as there were many points of interest in the original methods adopted and in the routine work since laid out by Mr. Littell, the manager. The power-house has twice been very fully described in The Electrical Engineer, especially the fine outfit of Ball engines, Hammond engines, Edison generators, Babcock & Wilcox boilers, etc.

A word of praise is due to Mr. George F. Porter, Secretary of the Association, for his good work. It was a matter of general comment that never before had the N. E. L. A. enjoyed so smooth-running a Convention and such complete arrangements. A specially good feature was the system of distributing badges. Hitherto it has been the custom to give out badges indiscriminately. This time, however, the bellboys and bootblacks had to go without. Each company was furnished with a button badge for its representative, whether active or associate, and other ribbons were provided for visitors and extra representatives. For these ribbons, silver buttons were furnished at the moderate charge of $1, while an equal sum would also buy a badge pin for the ribbon of any of the ladies of the Convention. In this way, the distribution of the badges was kept within proper bounds, yet all could get them who were entitled to them for their membership dues, or as visitors were willing to pay modestly for the distinction and for all the privileges that wearing the button conferred.

A full programme of business had been arranged for Wednesday afternoon, but it was wisely decided to postpone the session until the evening, so that the Convention might inspect the Niagara Hydraulic tunnel. A special invitation was received from Mr. Rhodes, the president of the Niagara Falls Brush Co., and from C. B. Gaskill, president of the Niagara Power Co.; Messrs. Burbank and Porter, engineers of the Cataract Construction Co., and Rodgers and Clement, the contractors. A special train was kindly furnished by the N. Y. Central R.R. Co., and it was fully loaded by about 350 members and ladies. On arriving at Niagara Falls the ladies were received by Mrs. Rhodes, and after being driven around the Falls in carriages, were entertained at her residence. The masculine part of the Convention devoted itself meantime to a very thorough inspection of the 1¼ mile of tunnel already made, and then visited the Brush station, where Mr. Rhodes, with his wonted hospitality, had prepared lunch and a punch bowl which showed how familiarity with a great body of water breeds contempt for it. Such of the members as restricted themselves to but one glass of punch also visited the Suspension Bridge, or coasted in a most reckless manner on the ice mountain below the American Fall. The train returned a little after five, and, as if to intensify the pleasure of the occasion, ex-President Cleveland passed through just ahead of it on a special train—an opportunity that was made the occasion of no little cheering and handshaking. Altogether the afternoon was a holiday long to be remembered, and its beneficial effects were seen in the zeal with which the business programme was attacked in the evening.

The Convention was brought to a close by a banquet given by the citizens of Buffalo, to the National Electric Light Association, on Thursday evening, at the Buffalo Board of Trade. Between 350 and 400 gentlemen sat down to table about 8.30. The large hall was beautifully decorated and the effect was greatly enhanced by standards of small incandescent lamps, with colored shades and draped with smilax, placed on the several tables. The floor had to be specially wired for this work, and the work was not at all of an easy nature, but the result was eminently creditable to F. P. Little & Co. who made and carried out the design. The menu was an excellent one, with choice wines to grace it, and it was printed in a very tasteful and orignal manner on heavy cards, with elaborate ornamentation including views of Buffalo and a satirical drawing of the conditions in which electric light stockholders find themselves. Mr. Scatcherd, president of the Board of Trade, acted as toastmaster, and after a few words of welcome from Mr. Huntley, the retiring President, the following programme of speeches was gone through: "The City of Buffalo," Mayor C. F. Bishop; "The National Electric Light Association," Hon. E. A. Armstrong; "Buffalo Manufacturers" Richard K. Noye; "Municipal Lighting," C. H. Wilmerding; "Buffalo Electricity," John G. Milburn; "The New President," James I. Ayer; "The Electrical Press," T. C. Martin; "The Buffalo Press," Mr. Kingsley of the *Enquirer*; "Electricity," Prof. Elihu Thomson. "Our Partners in Niagara Falls," A. J. Corriveau; "The Dusty Miller of Buffalo," George Urban, Jr.; and "The Electrical Congress of Chicago," Dr. Elisha Gray. The banquet closed about 1.15 a. m.

CONVENTION NOTES.

The Thomson-Houston Carbon Company were represented by Mr. D. T. Urquhart, who appeared to know every one and to be known by every one.

J. H. Bently represented the Century Pottery Co., of Camden, N. J., and was kept busy telling the merits of his company's productions as used in electrical work.

The Bryant Electric Company, of Bridgeport, Conn., had Mr. W. C. Bryant on the field again, and showed their usual line of Bryant sockets, switches, cut-outs, etc.

Frank Ridlon, of Boston, was there too, and exhibited himself in all his imposing grandeur to his numerous friends and gave absolution to all who required it—and they were not few.

The Eco Magneto Clock Company, of Boston, were represented by Mr. C. A. White, of Boston, who demonstrated the value of his system of watch clocks to all interested in that branch of electricity.

The Ashton Valve Company, of Boston, were represented by Mr. C. W. Houghton, of Boston, who seemed to know all the central station men, and explained the advantages of using Ashton pop safety valves.

The Economic Electric Manufacturing Company, of Boston, were represented by Mr. Titus, who did not show any samples but depended chiefly on the well-known reputation of the Economic lamp for his text.

The Johns Pratt Company, of Hartford, were represented by E. B. Hatch, of Hartford, who advocated strongly the use of Vulcabeston spools for all dynamos and motors, and for electrical insulation generally.

The Bernstein Electric Co., of Boston, were represented by Mr. C. A. Fish, who brought with him a few samples of the well-known Bernstein incandescent lamps, sockets and other specialties.

The Standard Electric Time Co., of New Haven, Conn., were represented as usual by Mr. C. D. Warner, who showed a few samples of their clock movements, and also samples of the well-known Warner electric gauge.

The Simplex Electric Company, of Boston, were represented by Mr. J. H. Mason, of Boston, who had a few samples with him of the favorite Simplex wire, and his pockets full of "testimonials" from all over the country.

The Samson Cordage Works, of Boston, were represented by their treasurer, Mr. H. B. Pratt, of Boston, who induced many to believe during his stay in Buffalo that the Samson cord was the correct thing for suspending arc lamps, and for trolley cords.

Kerite.—The interests of "Kerite" were taken care of by Mr. F. W. Cushing, general Western agent, and Mr. Wm. H. Eckert, general agent. Mr. Eckert has been on a trip through the West, and spent one or two days at the Convention while returning.

The W. T. C. Macallen Company, of Boston, were ably represented by Mr. Louis McCarthy, who showed to all interested samples of his insulated joint for gas and electric fixtures, a joint which has met with much success since its introduction a few months ago.

Hart & Hegeman, of Hartford, Conn., were well represented by their new treasurer, Mr. A. H. Pease, who made a large number of friends, and interested all in the Hart snap switch in various sizes. The large 60-ampere one seemed to meet with general favor.

The Benedict & Burnham Manufacturing Company, of Waterbury, Conn., had as a representative, Mr. D. L. Hungerford, of New York, who had a few samples of their insulated wires on exhibition. Their new "Benedict" wire seemed to meet with general approbation.

Jewell Belting Company, of Hartford, Conn., were represented as in past years by Mr. C. E. Newton and Mr. C. L. Tolles, who seemed to find an opportunity occasionally in the midst of their other pursuits to discourse on the merits of cutting dynamo belts from the *centres* of hides and centres only.

The Perkins Electric Switch Company, of Hartford, were represented by Mr. Bunch, of Hartford, who made his maiden trip to an electric light convention, but went away with a pleasing memory of Buffalo. Incidentally, Mr. Bunch showed a few samples of the Perkins switch, rosette cut-out and other specialties.

The Boston Braid Manufacturing Company, of Boston, who manufacture a very fine quality of silk braid, exclusively used for the filaments of incandescent lamps, were represented by Mr. Paul G. Fieldler, of Boston, who had his pockets full of samples, which were eagerly sought by the lamp manufacturers present.

The American Circular Loom Company, of Boston, were represented by their general manager Mr. H. H. Brooks, of Boston, who showed a number of samples of the well and favorably known Canvas Jacket insulated wires, and also of their new interior conduit, which is also protected by the canvas jacket covering.

H. B. Cutter, of the Cutter Electrical and Manufacturing Co., was not wearing bracelets as was supposed by a great many, but was simply employing a convenient method of carrying a section of his new flexible metallic tubing for portables and brackets. Their handsome double push-switch enjoyed a great deal of attention also.

The Chapman Valve Manufacturing Company, of Boston, had on the ground, their popular representative, Mr. E. L. Ross, who is well posted on all the steam engineering problems of the day. Mr. Ross says that the Chapman valve is the ideal valve for high pressure steam, and electric light and power plants are rapidly adopting it.

The Consolidated Electric Manufacturing Company, of Boston, were represented by their well-known general manager, Mr. C. E. Bibber, who showed a few samples of their well-known specialties, such as sockets, jack-knife switches, rosettes, etc., etc. Mr. Bibber also gave away a very neat little card counter, which was highly appreciated.

The Beacon Vacuum Pump and Electrical Company, of Boston, were fortunate in securing a space in the hall of the hotel, and the indefatigable Mr. S. S. Sherman, of Boston, soon had a number of the Beacon lamps from 16 to 150 c. p., all brilliantly illuminated. The Beacon Company are young, but they made a "strike" at the Buffalo Convention.

The Gould & Watson Company, of Boston, were well represented at the Convention, and showed samples of their new waterproof sockets made to fit either Thomson-Houston, Edison or Westinghouse base. Mr. E. P. Sharp, who had charge of the exhibit, showed also a few samples of the new Whitney voltmeter and ammeter, for which they are sole selling agents.

Mr. A. L. Ide, of Ide engine fame, was at the Convention.

Mr. A. H. Bauer, of the Pullman Palace Car Co., was on the ground.

Mr. Geo. E. Fisher, of the Commercial Electric Co., of Detroit, was there.

Mr. E. Rubel, manager of the St. Louis Electrical and Supply Co., was in attendance.

Chas. E. Jones, of Jones Bros., Cincinnati, was on hand. He will also be at St. Louis.

Mr. W. A. Fenn looked after the interests of the American Electric Supply Co., of Buffalo.

John A. Roebling's Sons Co. was well represented by Mr. H. L. Shippy and Mr. F. H. Sparling.

Mr. Frank De Ronde represented the interests of the Standard Paint Co. in an unusually genial manner.

Mr. W. J. Ashton, of the Dayton Fan and Motor Co., of Dayton, O., was present through the Convention.

Mr. A. B. Laurence, of the Shultz Belting Co., was well furnished with samples of the famous Shultz belt.

The Jenney Electric Motor Co., of Indianapolis, were represented by Mr. Chas. D. Jenney at the Convention.

Mr. Chas. Rodman, of the Globe Carbon Co., of Ravenna, O., was here and there and everywhere during the Convention.

Mr. Chapman, of the Akron Electrical Mfg. Co., was present during the Convention telling about the apparatus he manufactures.

Mr. F. P. Little, of Buffalo, was around all the time. He was able to show a number of fine plants installed by his company.

Mr. H. K. Gilman, manager of the Great Western Electric Supply Co., put in an appearance and was warmly welcomed on all sides.

Mr. W. D. Graves represented the W. D. Graves Electrical Manufacturing Co., of Cleveland, which is building a low-tension arc lamp.

The Eureka Tempered Copper Co. made a fine exhibit of their tempered copper specialties and were represented by Mr. N. S. Possons.

Mr. W. B. Roberts, general manager of the Rockford Electric Mfg. Co., of Rockford, Ill., was present and looked after the interests of his company.

Mr. Chas. E. Bibber, general manager of Consolidated Electric Mfg. Co. of Boston, was at the Convention and made things hum for his company.

Mr. Geo. H. Meeker, Chicago manager of the N. Y. Insulated Wire Co. was in attendance and Grimshaw and Vulca duct were right in it all the time.

Mr. B. F. Miles, of the National Carbon Company, received his usual hearty welcome. He has a host of friends, and his carbons are always in demand.

Pass & Seymour showed a fine assortment of their vitrified china specialties and several of their representatives were on the ground doing the honors.

Mr. Fred. V. Doty, general manager of the Aluminum Carbon Co., of Buffalo, was around all the time looking after the wants of central station men for his carbons.

"Ajax" Van Nuis had the combination but kindly distributed the key to all desirous of securing "protection" from it. Test it in a genuine electric storm and be convinced.

The Detroit Motor Co. were ably represented by Mr. Van Court and Mr. Armour, who made a very elaborate exhibit of their motors and generators, rheostats and switches.

Mr. R. N. Lovell, of the Lovell Mfg. Co., of Erie, Pa., was present. He did not bring a motor, however, as customers are taking them faster then his shop can turn them out.

Mr. W. B. Cleveland, of the Forest City Electric Works, Geneva, O., attended the Convention and explained the advantages or his specialties for lighting and railway work.

Mr. A. P. Seymour, of Pass & Seymour, Syracuse, joined the electric special contingent at Syracuse, and was at all times willing to be consulted regarding the specialties of his company.

The Indiana Rubber and Insulated Wire Co., of Jonesboro, Ind., were looked out for by Mr. Butler, who had some fine sample cases of the company's Paranite wires and cables.

The Security Porcelain Insulator was one of the novelties, and Mr. A. S. Brown was very successful in getting rid of a trunkful of samples. The insulator claimed a great deal of attention.

The Keystone Electric Co., of Erie, showed their reversible motors, and the attention they attracted was very noticeable. Mr. C. J. Sturgeon was on hand to explain the mysteries of the only instantaneously reversible motor that operates with a special switch and entirely without rheostats of any kind.

The Falls Rivet and Machine Co., of Cuyahoga Falls, O., distributed a handsome circular list of some of their power transmission plants. Mr. E. L. Babcock, president of the Co., was in attendance.

Mr. Henry B. Oakman, of the Buffalo office of the Edison General, made a most striking exhibit in their handsome store, and had a large bottle of ink ready for his many friends and correspondents.

The Okonite Company occupied parlors E and C of the Iroquois and were ably represented by Captain Candee, Col. Geo. T. Manson and their local agents, Messrs. Morse & Eames, of the Buffalo Engineering Co.

Mr. W. D. Packard, of the New York and Ohio Co., was present to tell all about Packard perfected incandescent lamps. He was quite satisfied with a little record of tests he found posted up in the Niagara Falls Brush station.

Col. J. H. Shay, of the Munson Belting Co., was right on the spot, as he always is at Conventions, and held up his end in his usual accomplished fashion. He is the only man in the world who has ever "caned" a whole Convention.

The Otis Bros. Electric Elevator Co. were on hand with one of their new electric pumps, an exceedingly ingenious piece of machinery. It was operated by a one-half horse power Crocker-Wheeler motor. Mr. A. E. Hall explained its merits.

The Hill Clutch Works, of Cleveland, had their Mr. S. S. Leonard, on the ground with some very handsome photographs of their clutches and transmission machinery in the Brush station. Mr. Leonard chartered a bus and took all those interested to see the plant.

The Mitchell-Brant Copper Co., of Erie, Pa., were represented by Mr. A. L. Daniels who exhibited a number of tempered copper commutator segments. They manufacture a segment exactly to angle guage, guaranteed pure copper and of a quality and workmanship to satisfy the most critical.

The New York Insulated Wire Co. had an A1 delegation of representatives. George Meeker, who has been in charge of the Western business since the opening of their branch in Chicago, was there, and all were glad to see him. J. W. Godfrey was there, of course, and all well remembered Gus. Noll and C. A. Place, as being present.

The Eddy Electric Manufacturing Company, of Windsor, Conn., were represented by Mr. A. D. Newton and Mr. M. E. Baird, and circulated around amongst their innumerable friends in their own happy way. They say that they never require to bring samples of their motor now-a-days; it is too well known, and besides there are any quantity of them in every city you can go to.

Claflin & Kimball, of Boston, who are now the sole selling agents for the Mather Electric Company of Manchester, Conn., and the Perkins Electric Lamp Company also of Manchester, Conn., were represented by Mr. Charles J. Hill, who seemed to impress the Convention with the fact that the Perkins lamp was a good one, and that the Mather dynamo would now be more popular than ever.

The Electric Pole Switch Company, of 36 Niagara street, Buffalo, showed a very novel arc light pole switch. The wires are attached to a separate and stationary base; the trimmer draws the lamp toward him preparatory to trimming, and the instant the lamp leaves the base or switch all connections are severed, and danger thereby averted. When the lamp is pushed back into position, the connection is again made almost automatically.

Mr. George Cutter, of Chicago, was around talking the merits of a new lamp-hour recorder, of which he has sold 100 to a single station, and he has now ready for the market some 500, which will probably disappear very rapidly. This recorder is adapted for either continuous or alternating currents, and also for arc lamps, which is somewhat of a new feature, so that a man can have his arc lamps on tap and use them just as he desires.

The Electrical Appliance Company, of Chicago were represented by their president Mr. W. W. Low who had his pockets full of Paranite wire, swinging ball lightning arresters, and their other specialties. Mr. Low also made arrangements to handle several new specialties of general utility and from which he expects a large sale amongst the central stations of the West. He also exhibited New England and Acme switches and several other new and valuable devices.

Mr. J. D. McIntyre took excellent care of the interests of the Electric Engineering and Supply Co., of Syracuse, showing a number of their popular specialties. Noticeable among these was their new incandescent locking switch, also a specially designed porcelain tube for use in running wires through partitions, etc. The locking switch is designed for use in hotels, theatres and public places generally where ordinary switches are used by the crowds as an object of amusement rather than the use for which they are intended. The attendant has his key and uses it when desired.

Prof. R. O. Heinrich was untiring in his efforts to entertain his many friends and the friends of the Weston Electrical Instrument Company.

F. P. Little & Co., at their store, 141 E. Seneca St., showed some of the Crocker-Wheeler motors. The motor company was represented by Dr. S. S. Wheeler.

Partrick & Carter Co.—The interests of Partrick & Carter were well taken care of by Mr. E. Ward Wilkins. They gave out a very neat little memorandum book.

The Findley Mast Arm manufactured by the Utica Electric Mfg. and Supply Co. was shown and its good qualities explained by Mr. Findley at 270 Iroquois Hotel.

Captain William Brophy, of the Fire Underwriters' Union, was circulating around the Iroquois Hotel, renewing all his old friendships and forming many new ones.

Thomson Recording Watt Meters were exhibited at the Iroquois in Parlor 62. No little interest centered there as was evidenced by the number of delegates and visitors wearing *seals* which were attached to all who visited this exhibit.

Mr. J. K. Martin represented Jas. J. Murray & Co., of Philadelphia, and it was a pleasure to see him entertaining the numerous visitors at his parlor where he showed a very handsome line of arc and incandescent globes in rich cut and flint glass.

Mr. Elias E. Ries, president of the Ries Electric Specialty Co., of Baltimore, was there with his ingenious regulating socket. The wonderful success of this novel socket in the six months just passed is too well known to necessitate any recapitulation.

Mr. Richard R. Whithead, vice-president and treasurer of the Crescent Insulated Wire and Cable Company was there in the interests of, and took every opportunity to extol the merits of, his company's wires. This was Mr. Whithead's first Convention and he certainly made a host of friends.

The American Electric Works, of Providence, R. I., were represented as usual by Mr. P. C. Ackerman of New York, who appeared to enjoy himself in his customary happy way, and succeeded in interesting all in his samples of electric light wires and cables and all the other products of the large factory in Providence.

The Union Electric Manufacturing Company of Bridgeport, Conn., were represented by Mr. J. M. Orford, of that city. Mr. Orford always goes provided with a socket in his pocket, and was ready to prove conclusively to one and all that the Union socket was one of those things, that only the best were worth having, and that he had the best.

The Stanley Electric Co. of Pittsfield, Mass., were well represented by Mr. Stanley and Mr. H. Hine, the former taking an active part in the discussions while the latter devoted himself to the pressing business matters of the hour, a great many of the delegates desiring to get particulars as to the Stanley converters, alternating current motors, etc.

Mr. C. P. Corey, treasurer and general manager of the Electric Construction and Supply Co., was here, there and everywhere, and it is needless to say that the "Ward Lamp" interests received all the attention required. Mr. Corey made a beautiful exhibit of their photo-engraving lamp and their search-light, both operating on 110-volt circuit.

The National India Rubber Company of Bristol, R. I., who have within the past year commenced the manufacture of high-grade insulated wires and cables, were ably represented by the manager of their electrical department, Mr. F. S. Minott, of Bristol. This was Mr. Minott's first visit to an electric light Convention, but he soon made numbers of friends and interested many in the excellent quality of his samples.

The Electric Secret Service Co. were represented by Mr. C. P. MacKie, Mr. Robt. MacKie and Mr. S. S. Bogart. They showed their individual motor and arc light cut-out, the working of which seems almost miraculous as they were able to demonstrate the possibility of cutting around any number of lights and cutting in or out at will any particular light desired. This certainly novel device must be seen to be appreciated.

C. S. Knowles, of Boston, who are large dealers in the finest quality of porcelain goods for all electrical purposes, had a very pretty line of samples in the care of their Mr. Bell, of Boston. Mr. Bell showed some very interesting samples of his goods to many of those present, and seemed to make a very favorable impression. Mr. Knowles, besides dealing in porcelain goods, has a number of other articles equally interesting to the electric public.

Utica Electric Mfg. & Supply Co.—A great deal of interest was centered around Room 270, where a genial delegation represented the Utica Electric Mfg. & Supply Co. This company are just introducing some very novel specialties, so much so in fact that they must be seen to be appreciated. Mr. Brayton, Mr. Bossart and Mr. Findley did the honors. A full description of a most ingenious type of lightning arrester and quick-breaking and absolute-locking switch is impossible at this writing. They issue circulars however that explain fully the workings of their devices.

Knudson-Cuttriss Wire Co.—The new K. C. wire made by this company of the Drexel Building, New York City, was exhibited in Room 104 of the Iroquois Hotel. While the Convention remained in session, two large coils were kept submerged in water with 110-volt current passing through it, but not the slightest leakage was shown. As this wire is of the fibre class, with no rubber or gutta-percha in the material used for insulation, this test excited much attention and interest among wire men.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEBRUARY 16, 1892.

Accumulators:—

Storage Battery, C. P. Elieson, 469,129. Filed June 4, 1891.

Employs electrodes built up of a series of corrugated envelopes.

Alarms and Signals:—

Signal for Electric Railway Systems, F. A. Cheney, 468,787. Filed Sept. 10, 1891.

A system of electric block signals for electric railways.

Means for Indicating Discharge from or into Hoppers, F. H. Briggs, 468,970. Filed Apr. 29, 1891.

Conductors, Conduits and Insulators:—

Electrical Conduit, E. T. Greenfield, 469,208. Filed May 13, 1891.

Claim 7 follows:

'A conduit tube consisting of two tubes of insulating material completely surrounded by a metallic sleeve which joins them together.

Distribution:—

System of Distribution of Electrical Heating Currents, G. D. Burton, 468,938 Filed May 14, 1891.

Has for its object to distribute heating currents of different volumes for forging, etc.

Dynamos and Motors:—

Commutator-Brush for Electric Motors and Dynamos, T. A. Edison, 468,950. Filed Apr. 4, 1891.

Consists in an arrangement with bridges of high resistance between the commutator bars.

Field Magnet for Dynamos and Motors, R. Lundell, 468,953. Filed June 6, 1891.

A multipolar motor occupying small space and efficient and of low speed.

Armature for Dynamo-Electric Machines, M. Deprez, 469,080 Filed Dec. 7, 1885.

An armature coil constructed in separate sections which may be slipped on and off without disturbing each other.

Dynamo-Electric Machine or Motor, H. M. Byllesby, 469,193. Filed June 8, 1891.

A dynamo or motor having concentric field magnets and armature, both journaled in suitable bearings and free to rotate, the one within the other.

Galvanic and Thermo-Electric Batteries:—

Electrolytic Cell, E. A. Le Sueur, 468,880. Filed June 6, 1891.

Electrolyte Solution for Galvanic Batteries, S. Miller, 468,887. Filed Oct. 16, 1891.

An electrolyte consisting of nitrate of soda, bichromate of potash, chloride of sodium and sulphuric or hydrochloric acid, or both.

Lamps and Appurtenances:—

Electric-Arc Lamp, R. S. Dobbie, 469,041. Filed Oct. 23, 1890.

Has for its object to produce a smooth and even feed and also to automatically re-form the arc when broken.

Suspending Device for Electric Lamps, J. J. Renehan, 468,048. Filed Jan. 30, 1888.

A yard arm for arc lights.

Electric Search-Light, N. Weeks, Jr., 469,050. Filed June 4, 1891.

Electric-Arc Lamp, H. Sawyer, 469,093. Filed Feb. 24, 1891.

An arc lamp automatic in its action carrying a number of carbons and supplying them to the holders when required.

Miscellaneous:—

Magnetic Lock, A. E. Kintner, 468,807. Filed Sept. 3, 1891.

Electric Elevator, R. C. Smith, 468,903. Filed Aug. 28, 1891.

Electric Brake Mechanism for Elevators, C. E. Moore, 468,917. Filed Nov. 4, 1891.

Coin-Freed Machine for giving Electric Shocks, J. Mason, 468,955. Filed Mar. 14, 1891

Electric Curling-Iron, A. F. Godefroy, 469,135. Filed June 26, 1891.

Electric Letter Box, C. A. Pinkham, 469,181. Filed July 3, 1991.

Railways and Appliances:—

Trolley for Electric Cars, J. W. Beebe, 468,779. Filed Mar. 10, 1891.

Has for its object the diminution of friction, the prevention of loss of force resulting from an accumulation of ice on the wire and the maintenance of a constant contact.

Turn-Table Connection for Electric Railways, R. M. Hunter, 468,912. Filed Feb. 17, 1886.

Electrically Propelled Car, H. E. Dey, 468,948. Filed July 14, 1891.

A system of gearing consisting of two rotary pumps, the one on the armature shaft and the other on the driven axle connected by pipes.

Converter System for Electric Railways, T. A. Edison, 468,949. Filed March 8, 1887.

Has for its object to overcome the loss from leakage on the contact conductors of electric railways.

Electric Railway, F. J. Sprague and P. F. O'Shaughnessy, 468,959. Filed Jan. 19, 1889.

Has for its object an arrangement of the switch plate in a trolley system such that the contact device will be readily guided to its proper outlet.

Switches and Cut-Outs:—

Multiple Switchboard, W. Moseley, 468,818. Filed Dec. 26, 1888.

An arrangement whereby, when a line is once connected at one board, the fact of such connection is made known automatically at other boards.

Electric Cut-Out, V. A. Thomas, 469,220. Filed May 15, 1891.

Telephones and Apparatus:—

Telephone Transmitter, E. A. and T. Grissinger, 469,085. Filed Sept. 16, 1891.

Claim 1 follows:

In a telephone transmitter a diaphragm consisting of a film of suitable material enclosed by a substantially homogeneous strongly coherent body of carbon.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The Buffalo Convention was a good advertising medium, but the technical journals are better.

THE "AMERICAN" HIGH-SPEED ENGINE FOR ELECTRIC LIGHTING.

THE direct connection of the steam engine with the dynamo presents such well-recognized advantages that they require no further elaboration, but it is evident that with a reciprocating engine the speed is limited. To overcome this drawback Mr. Elmer Stillman Smith has designed a novel type of engine which is now being built in a variety of sizes by the American Engine Co., of Bound Brook, N. J.

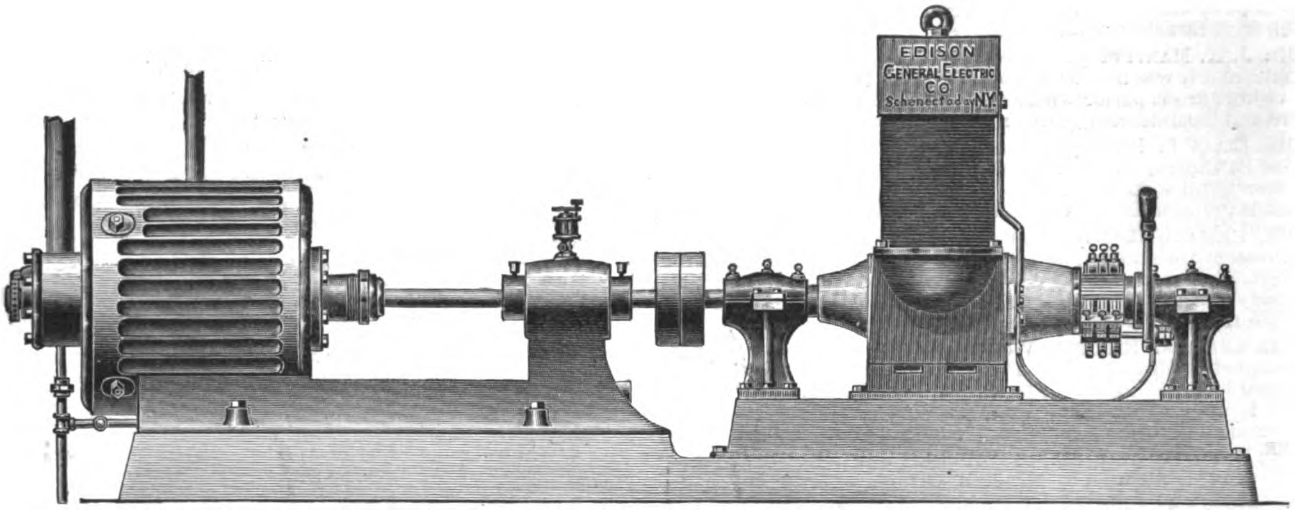

FIG. 1.—"AMERICAN" HIGH-SPEED ENGINE COUPLED DIRECT TO DYNAMO.

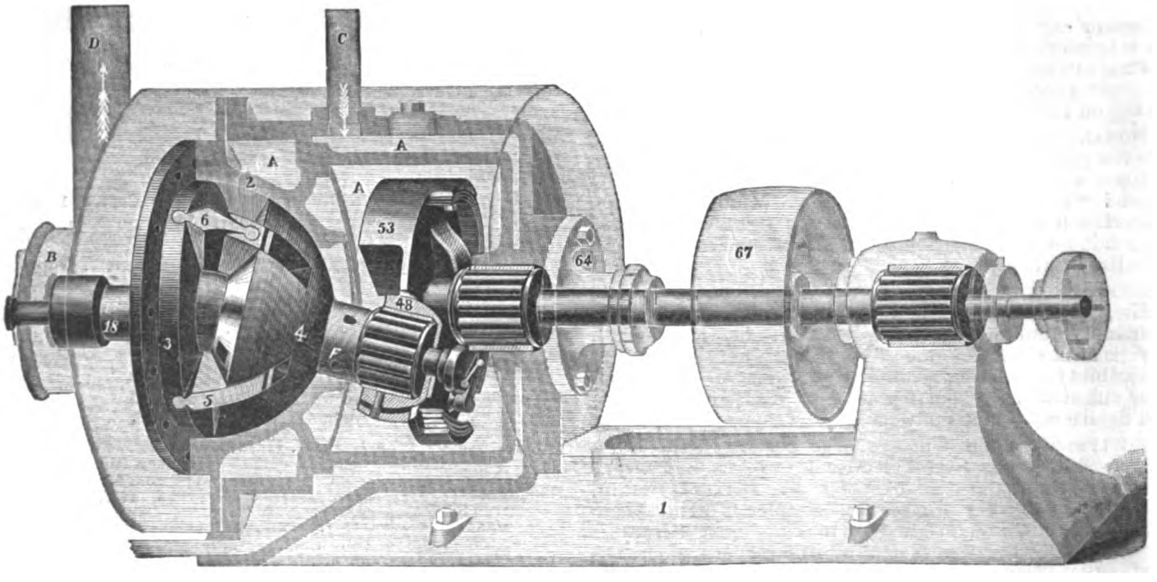

FIG. 2.—MECHANISM OF "AMERICAN" HIGH-SPEED ENGINE.

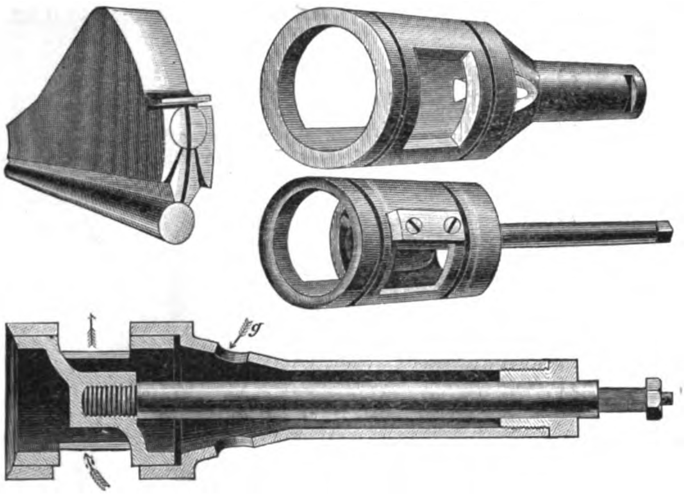
The general appearance of the engine connected to a dynamo is shown in Fig. 1. Although the engine has no dead centres, it is not a rotary engine in the true sense of the word. This will be recognized by an inspection of Fig. 2, which shows the outer parts of the engine in transparency and the working parts in full lines. In the same engraving, A is the steam chest, B the exhaust chest, C the live steam pipe and D the exhaust pipe. The cylinder is bolted to the bed, and projects into the steam chest, which gives it a live steam jacket. Radiation from the steam chest is prevented by by outer jacket. The cylinder has a circular opening through which projects the piston stem F. This opening admits steam against the back of the piston, its area being so proportioned as to balance the pressure of steam in the compartments at the face of the piston, thereby preventing friction between the piston and cylinder. The space between the piston and cylinder head is divided into four compartments by partition blades, 5 and 6, Fig. 2, one of which is shown in detail in Fig. 3. These blades have a pivot connection with the cylinder head, as shown in Fig 2, which allows them to accommodate the movements of the piston. The sides of the blades radiate from the centre of motion, and wear between them and their bearings against the piston is taken up automatically by a spring advancing them toward the follower pin, 18, Fig. 2. The latter is hollow, and connects the exhaust chest with the valve chamber in the piston, and also furnishes an abutment for packing strips in the ends of the blades. The opposite ends of the blades have packing strips also, to prevent leakage of steam from one compartment to another.

The crank disk and shaft are supported in frictionless roller bearings, as shown in Fig. 2, which work in steel bushings in the bed plate castings, the wear on the shaft being taken by steel sleeves. The piston stem bearing in the crank disk is of the same construction. All these parts are hardened and ground true.

The main and cut-off valves are shown in Figs. 4 and 5, and a section through both is shown in Fig. 6. They are located inside the piston, and bear against the follower pin, 18, Fig. 2, describing a circle at each revolution, together with the piston stem and crank disc, about the axis of the shaft, the radius of the circle decreasing towards the follower pin. The main valve also turns on its axis, being rigidly connected to the spherical bushing (48, Fig. 2), which is connected to the crank disc by a screw. This valve controls the admission of steam to the steam compartments, and also the exhaust. The cut-off valve controls the time of closing the steam port. Its stem extends through the main valve stem to the back of the crank disc, where it connects with the governor weight by steel rods *q* and carrier plate R, Fig. 7, the end of the stem being shown at *n*. Steam is admitted from the steam chest through the apertures shown in the piston stem F, Fig. 2, to the inside of the main and cut-off valves, at *g*, Fig. 6; thence, in the course indicated by the arrow, through a passage in the piston, shown above and to the right of 5 in Fig. 2, into one of the compartments, where it forces the piston away from the cylinder head. When the action of the cut-off valve shuts off the steam, the stroke is completed by expansion. As the valves revolve, the port of this compartment is put in communication with the exhaust port of the valves, and the exhaust passes out as indicated by the lower arrow in Fig. 6, through the hollow follower pin 18, Fig. 2, to the exhaust chamber B and pipe D.



FIGS. 3, 4, 5 AND 6.

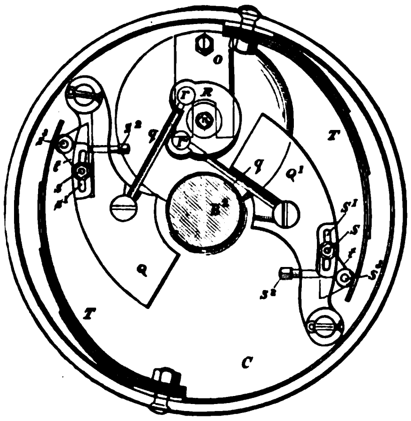


FIG. 7.

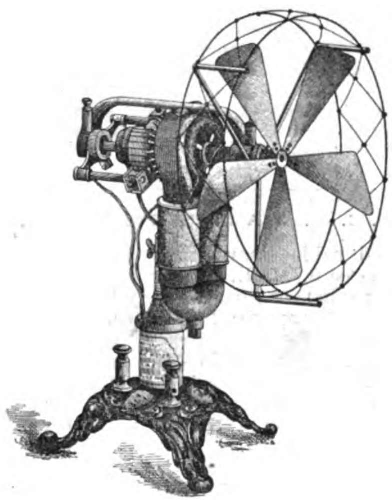
There is a diagonal partition in the cut-off valve, shown in Fig. 6, which separates the live steam from the exhaust. In the manner described, steam is admitted to one compartment after another until the stroke of revolution of the shaft is completed, the time of closing the steam port being controlled automatically by the governor so as to maintain a uniform speed under varying loads of pressures. The construction of the governor is clearly shown in Fig. 7. The main valve controls the admission and exhaust, which remain constant. The engine can be governed so as to run easily at any speed desired, up to a thousand revolutions per minute or more, the spherical segment which acts as a piston being so balanced as to insure smooth running and noiselessness. All moving parts except one bearing are lubricated with steam. The engine is compact and self-contained, taking up little room in proportion to power developed. It will work as well vertically as horizontally, and it may be hung overhead if desired, so as to be coupled directly to the main shaft. It may also be coupled to dynamos, circular saws, fans, blowers, etc. For marine use, elevators, etc., it is provided with reversing gear, and where a high degree of economy is desired, it is compounded.

THE CYCLONE ELECTRIC FAN.

THE accompanying illustration shows a novel style of fan designed by The La Boiteaux Electric Motor and Fan Co., of 376 Walnut St., Cincinnati, O. The chief peculiarity of these fans lies in their oscillating or rotary motion, by means of which the cooling current of air is equally distributed in all parts of a room. They are claimed to be entirely noiseless, and are especially adapted to large rooms used by many persons; the rotary fan being most suitable for offices, etc., while the oscillating arrangement has been found most convenient in hotel corridors, saloons, etc. Here the fan is placed upon the bar, or on a bracket on the wall, and moves slowly from side to side in a semicircle.

The rotary fan rests upon an enameled iron pedestal. While in motion, the motor and fan both revolve on their base at the slow speed of ten revolutions per minute, while the speed of the fan is 2,000 revolutions per minute. The double motion produces a cool wave of air, the effect of which can be readily felt at a distance of ten yards from the motor in all directions.

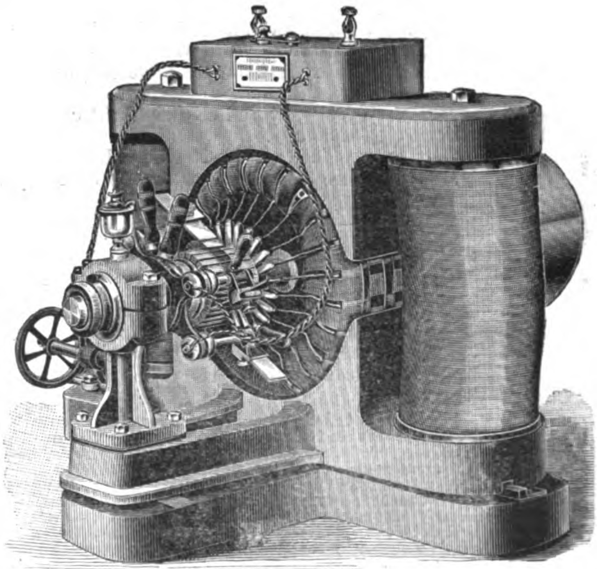


THE CYCLONE ELECTRIC FAN.

These devices are made in two sizes and can be attached to the ordinary incandescent circuit.

THE NEW DUPLEX ARC GENERATOR.

THE new arc generator built by the Duplex Electric Co., Limited, of Corry, Pa., possesses many of the general characteristics of their incandescent generators as will be seen by the illustration, which shows their 1,350 volt dynamo. It is of good design and simple in construction. This dynamo is a cool running, highly efficient series machine, and has an armature of the



THE NEW DUPLEX ARC GENERATOR.

closed coil type with 16 to 24 coils according to size, made so that any coil may be removed without interfering with the rest. The armature core is of the Gramme ring type, is constructed with special reference to perfect ventilation, and to prevent short circuiting.

The commutator is of hardened copper, thoroughly insulated with mica; in fact mica and wood are the principal insulators used throughout the generators.

The armature shaft is of best Bessemer steel and runs in carefully fitted phosphor bronze bushed boxes swiveled to insure alignment. They are made with wide fitted oil cups or self-oiling bearing to suit the purchaser. A hot bearing on these machines is unknown where ordinary care is used.

There are no rheostats or resistance coils used on this company's arc dynamo or on the incandescent generator, the regulation being accomplished on the arc dynamo by changing the position of the brushes on the commutator. When so ordered it is fitted with a simply constructed automatic regulator, which is sensitive to the slightest change of load and acts quickly and quietly by changing the position of the brushes.

This generator was designed by W. E. Cady, the electrician of the company, who has had a large experience in arc lighting machinery.

Every generator is thoroughly tested to its full load before leaving the factory, and they are made in any size ranging from 5 to 80 lights in 1,200 and 2,000 c. p. type.

N. I. R. SEAMLESS INSULATION.

The wires and cables manufactured by the National India Rubber Co., of Bristol, R. I., are now so well known and appreciated by the trade that this company is building a new plant which will increase its capacity four times.

Twenty-five years of experience with india rubber has given the company a thorough and minute knowledge of the manipulation of rubber in all its branches, and its application as insulation for electric wires is no new thing with them, for 18 years ago they applied rubber covering to wires for their own use, which wires are in use to-day with unimpaired insulation.

For a number of years Col. A. C. Eddy and other officers of the company have been experimenting with rubber insulation in conjunction with electrical experts, in the endeavor to produce a superior insulating covering.

The Massachusetts Electrical Engineering Co., of Boston, has been associated in these later tests. which have proved that only the best and most carefully-prepared rubber compound will make a good and lasting iusulation. The N. I. R. insulation possesses high insulating qualities, and is claimed to be less susceptible to the destructive influences of heat, cold, moisture and gases than that used by other companies.

Pure Lake copper and fine para rubber are used. The rubber covering is first pressed around the wire in a semi-plastic form, making a seamless covering, considered an important advantage over insulation having a seam on one or both sides.

It is then wound with rubber tape and covered with a braided weatherproof outer envelope. The whole insulation is then vulcanized. The wire is made with a black finish, or with a white fire-proof finish as desired.

Telephone and telegraph wires, switch cords, electric light and underground lead-covered cables are made in all the sizes called for, with a standard insulation resistance of 1,000 megohms per mile

A large quantity of their lead-covered electric light cables are in use in the New York city subways.

Mr. Samuel P. Colt is president of the National India Rubber Company, and Mr. F. S. Minott is manager of the wire department.

THE HEISLER ELECTRIC COMPANY.

The plant erected by the Heisler Electric Company, for the corporation of West Toronto Junction, Ont., Can., has been inspected and formally accepted by the town authorities. Mr. J. J. Wright speaks in the following terms of the installation, which certainly is an excellent endorsement of the work done by the Heisler Company:—

> "I have examined the plant installed by the Heisler Electric Company, and I find the work done in a thorough and workmanlike manner. The quality of the material used is good, the poles are of extra quality and well put up; in fact, the outside work reflects great credit on the men having had it in charge. The dynamo is well installed on a solid and durable foundation. and when examined by me was in thorough and satisfactory working order. The workmanship on the regulator is particularly admirable, and on trial performed its work well, keeping the current in both circuits perfectly even. The whole installation I consider first-class; in fact, it is a pleasure to be called in to pass judgment on work of this character."
>
> (Signed) J. J. Wright, Inspector.
>
> Toronto, Feb. 8th, 1892.

The Heisler Company also report the sale of a plant at Constantine, Mich., made through their agents, Messrs. Rheubottom & Bond, of Union City, who are doing excellent work in their territory, and are meeting with deserved success.

FRINK REFLECTORS.

In a letter to Mr. I. P. Frink, dated Columbus, O., of Jan. 6, 1892, Prof. B. F. Thomas. of the University, writes: "The lighting of the Senate and House Assembly rooms by electricity is giving most excellent satisfaction, and the reflectors furnished by you are much admired."

THE MESTON VOLTMETER SWITCH.

Fig. 1 is a prospective view of the apparatus, and Fig. 2 a diagram of the connections of the Meston voltmeter which is being manufactured by the Emerson Electric Mfg. Co. of St. Louis. The novel features consist in an improved form of self-adjustable contacts by means of which the connections are made with absolute certainty. The contact points are imbedded in the slate, so that their contact faces are flush with the slate. This arrangement avoids the possibility of short circuit. The connections are made by means of the brass studs which extend through the board, all connections being made at the back of the board. The switch is finely finished and elegantly designed, and is being well received by their customers.

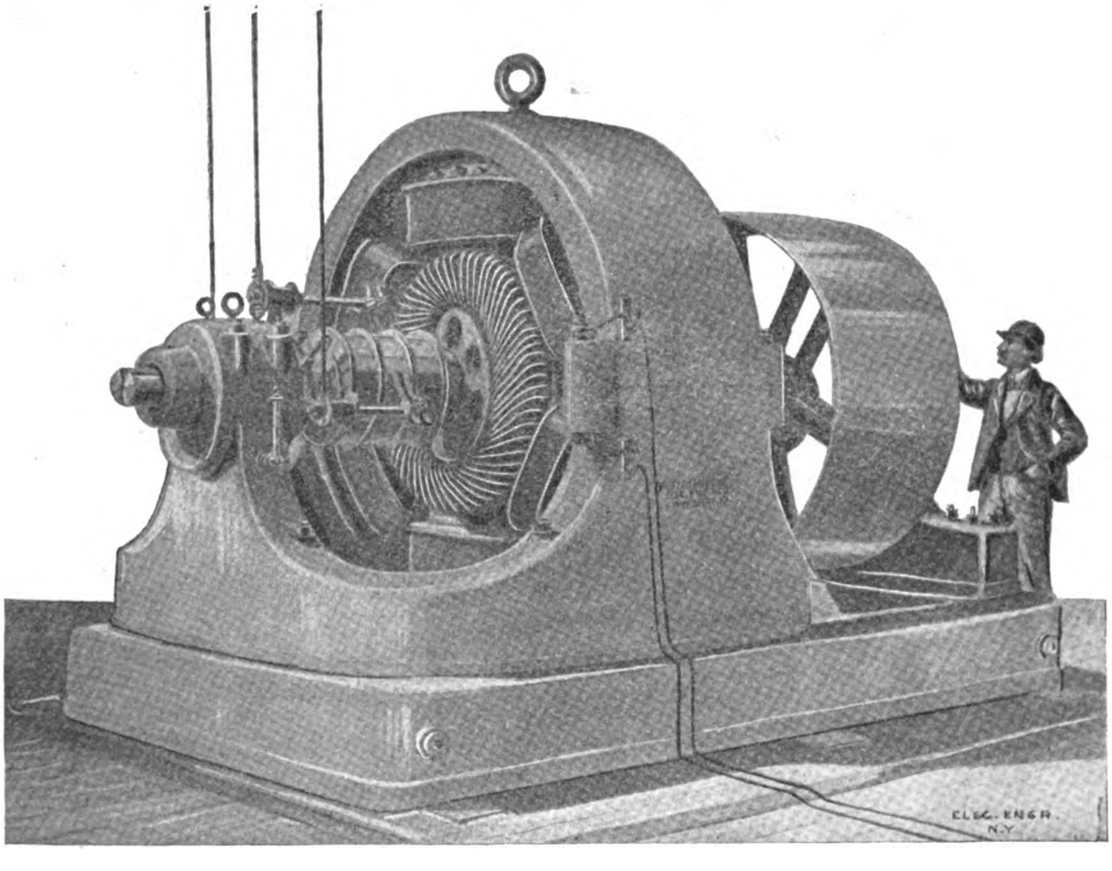
THE TESLA MULTIPHASE CURRENT MOTORS.

BY

Albert Schmid

THE prominence which has been given to power transmission by multiphase currents in the experiments between Frankfort and Lauffen, seems to have led to the impression, even among those otherwise well informed, that this was the first example of this method of transmission. It may therefore be well to put on record the fact that in this country multiphase motors manufactured by the Westinghouse Co. have been in successful commercial operation for several years, and a three-phase power plant has been in daily service in the shops of the Westinghouse Co. at Pittsburgh for some time past, driving the shafting and machinery of the winding department.



ELEC. ENGR. N.Y.

FIG. 4.—THREE-PHASE 1,000 H. P. TESLA ALTERNATING MOTOR.

As is well known, Mr. Nikola Tesla is the inventor of the multiphase motor, and his patents in this country are controlled by the Westinghouse Electric & Manufacturing Company, who have been quietly standardizing the different sizes and have, within the last year or two, placed a large number of them in service.

The generators for these motors are of the Westinghouse multipolar type with toothed, drum armatures wound to give currents of sixty or ninety degrees difference of phase. These machines, one type of which is shown in Fig. 1, are built either entirely self-exciting and self-regulating or separately-exciting and self-regulating. The machine shown is designed for 60 kilowatt capacity.

The motors are constructed with internal poles and grooved armatures. The larger motors have armatures with three collecting rings, and the fields are excited with direct current. The smaller ones have armatures wound with coils closed upon themselves, doing away with all collecting rings and commutators. The engraving Fig. 2, shows a 10 h. p. Tesla motor and Fig. 3 exhibits the armature removed from the enclosing field magnets. These multiphase motors are built in sizes of from 1 to 1,000 h. p.

A 1,000 h. p. three-phase generator or motor, for the same machine can be made either as a motor or generator, is shown in the engraving Fig. 4 and when run as a generator will give 150 amperes at 5,000 volts. In mechanical design this machine is similar to the multipolar direct current railway generators built by the Westinghouse Company. The armature is of the drum type with slots for the wire and is without bands.

With the Tesla multiphase system the power can be subdivided to any extent for motor or lighting purposes, and high pressures may be employed which can be reduced to whatever voltage is desired. The multiphase motors start under load, and run at constant speed. The smaller ones are made entirely alternating, and the larger ones are self-exciting after reaching synchronism.

As the starting torque with the Tesla multiphase motors is comparable with shunt wound direct current machines, they may be applied in every case where direct current shunt wound motors can be used. At starting, the direct current motors require dead resistance in series, which means considerable loss, but the alternating current motor has inductive resistance, and therefore the loss at starting is much less. Multiphase motors can be used for operating mines, factories, and street railways, and the generating station may be located wherever most convenient for obtaining the best results, and if the pressure is not over 5,000 volts, the motors may be supplied direct from the mains. The Tesla motor has a great advantage over other types of motors in that it requires no commutator, and consequently is sparkless. The motor may be boxed up, and kept free from dust and grit, and high pressures can be employed successfully. No starting resistance is required and the motor is small and compact, and requires no attention. Tests made at the Westinghouse Co.'s works demonstrate that the Tesla motors are fully as efficient as the best direct current motors.

ELECTRICAL ENGINEER, N.Y.

FIGS. 2 AND 3.—10 H. P. TESLA ALTERNATING MOTOR.

THE COST OF STEAM POWER.

BY

Chas. E. Emery.

I HAVE had several requests, particularly from electrical people, to revise my paper on the "Cost of Steam Power," published in Vol. XII, *Transactions of the American Society of Civil Engineers*, (November, 1883), to correspond to conditions as they exist at present. I have concluded to make a comparison of the relative cost of power in engines of different kinds, using a 500 h. p. unit in each case, reckoned as effective on a shaft running at 200 to 350 revolutions per minute, such, for instance, as the main shaft of a high speed engine or the jack shaft of a low speed engine.

I would not propose to discuss at this time the difference in the cost of producing different quantities of power or to go into the capitalized value of steam power as in the former case, but simply compare the relative costs of the power when the interest on the cost of different types of steam machinery is balanced against the economical results due to such differences in type, considering also different prices for fuel and the conditions as to continuous or occasional use.

To accomplish this, I must have approximately the cost at which 540 to 550 indicated horse power steam plants of different kinds can be erected in connection with, say, two or more similar units in the same station with prices ruling as at present, and I will be greatly obliged to engine manufacturers if they will send to me at their early convenience the following information duplicated for each type of engine which they regularly manufacture, such, for instance, in a general way, as simple engines, condensing or non-condensing, fast or slow speed; compound engines, condensing or non-condensing, fast or slow speed; and triple compound engines, condensing or non-condensing, fast or slow speed.

1. Ruling price for 500 h. p. engine delivered at an average distance from the works, price to include condenser and air pump if engine is condensing.

2. Probable cost of foundations under average conditions.

3. Probable cost of connections to boilers, condenser, pumps, etc., including felting, painting and completion ready for regular use under average conditions.

4. Probable cost of belting to jack shaft if engine be of slow speed.

5. Probable percentage of friction of engine.

6. Probable percentage of friction lost in transmission to jack shaft.

7. Probable water per indicated horse power per hour under average working conditions at or near rated load.

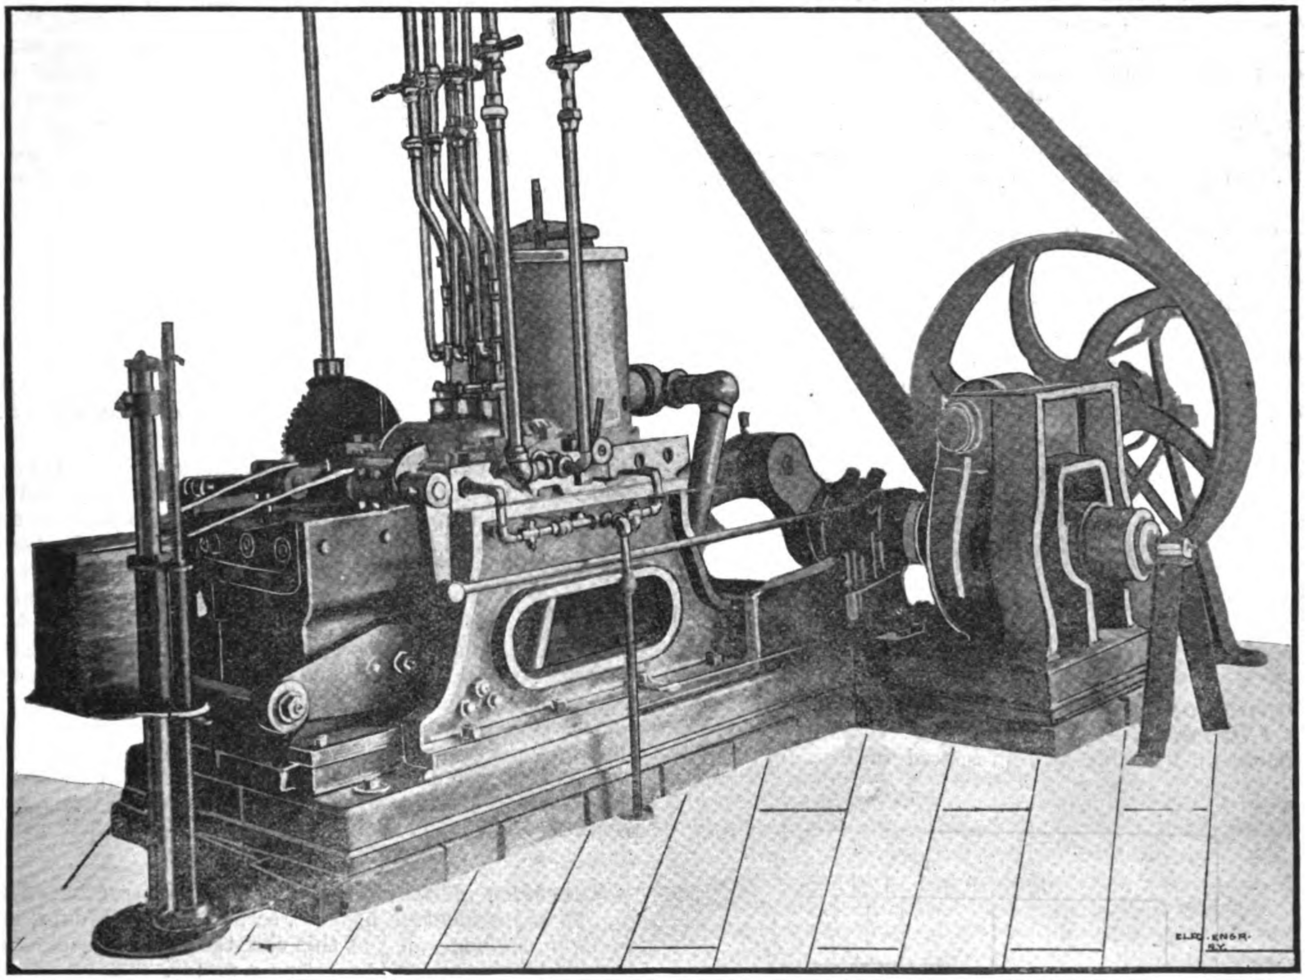
8. Probable cost of boilers, included setting, feed pumps and all connections ready for use, stating type of boiler proposed.

9. Probable cost for 100 surplus horse power of boilers.

10. Amount that should be allowed as a contribution toward cost of engine house, boiler house and chimney.

11. Probable cost of labor for 10 hours' operation which should be allowed for 500 h. p. unit in different parts of the United States.

12. Finally, state in a general way what information you have as to the ruling prices of coal delivered on the premises of consumers in different parts of the United States and its evaporative effect in the boilers which you refer to above.



MADDEN'S MACHINE FOR ROLLING STORAGE BATTERY GRIDS.

MADDEN'S MACHINE FOR ROLLING STORAGE BATTERY GRIDS.

WHILE much attention has been devoted to the chemistry of the storage battery and to some extent, also, to its mechanical construction, the fact remains that the methods originally employed are still largely retained in the manufacture of the cells. This is notably the case with regard to the making of the grids, which up to the present time have been cast in molds by hand, a tedious and expensive mode of operation. It was with the object of improving this branch of storage battery manufacture that Mr. A. F. Madden undertook the construction of an automatic machine for rolling storage battery plates on a commercial scale, for which a patent has recently been issued, and which we have had the pleasure of seeing in operation. Before entering upon a description of the machine we may premise that the inventor has been identified with the storage battery industry in this country since the beginning of its commercial history, having been one of the corps sent to England to observe the practice of the Electric Power Storage Co., of London, by its American licensee, the Electrical Accumulator Co, and having subsequently erected and superintended the well-known works at Newark, N. J. Mr. Madden's extended experience had convinced him that the best form of grid for the oxide of lead battery included the following characteristics: 1. Large area of contact between the conductor and active material. 2. Large area of surface exposed to the electrolyte. 3. Uniform distribution of the supporting conductor. 4. Perforations adapted to hold firmly the active material.

These requirements necessarily call for thin plates, containing a large number of comparatively small perforations, and considerable difficulty has been experienced in endeavoring to produce these commercially by the common method of hand-operated chills.

The machine designed by Mr. Madden is illustrated in the accompanying engraving. In brief, the process employed consists in rolling semi-fluid lead into a mold or "former" traveling back and forth under a roller, the grid being ejected at one end of the stroke. The turret shown at the right contains the lead and apparatus for heating. From below this, the lead is fed into an air-tight retort, closed at the bottom by a moving carriage containing the former. The latter is a masterpiece of mechanism, and though quite simple, would require an extended description to render its construction and operation intelligible. For the present purpose it suffices to say that, when under the retort, its movable divisions are lowered for the reception of the lead which is then crushed into it by the roller, and a reverse action at the other end of the stroke lifts the plate out.

An ingenious device is also provided for stacking the grids as they are delivered from the traveling carriage, as shown at the left.

One feature of Mr. Madden's grid is the shape of the perforations, the divisions between which, instead of increasing in thickness from their outer edges inward, have the same thickness throughout except at the edges, where a slight "burr," made in the manner described above, assists in holding the active pellets in place. The difficulty of freeing this form of grid from a mold has alone been an insurmountable obstacle in the way of casting it, but has been successfully met by Mr. Madden and forms one of the chief advantages of his machine.

After the grids leave the automatic machine they are passed through another machine which closes the perforations several thousandths of an inch all around by a slight "burr," and at the same time hardens them.

The machine is capable of turning out 5,000 grids in 10 hours, and produces not only a grid of high mechanical perfection but one of much tougher material than can be produced by casting. It is but the work of a few minutes to adjust the thickness of the grid made from one sixteenth to one-half inch. We may add that Mr. Madden's apparatus and patents are the property of Lloyd & Paxton, Limited, of this city, who are now carrying on an exhaustive series of experiments and tests, both here and abroad, in order to establish the superiority of these methods of lead battery construction.

THE PRACTICAL MANAGEMENT OF DYNAMOS AND MOTORS.—VI.

BY

Francis B. Crocker and S. S. Wheeler.

CHAP. IV.—*Continued.*

Dynamos on the Three-Wire System (Direct Current).—In the ordinary three-wire system for incandescent lighting as represented in Fig. 16, no particular precautions are required in starting or connecting dynamos. As a matter of fact the two dynamos are independent of each other and work on practically separate circuits. Dynamo 1 feeds the circuit formed by the mains marked + and N and dynamo 2 feeds the circuit formed by mains N and—. The "neutral" wire N merely acts as a common conductor for both circuits. The E. M. F. on each of these circuits should of course be kept constant at the prescribed voltage and therefore equal. The current on the two circuits or "sides" of the system as they are called, should be kept as nearly equal as possible by distributing the lamps equally between them. Any difference in current either way is carried by N. One dynamo may be run alone on one side of the system and the only effect of throwing on the other dynamo is to reduce the "drop" or fall of potential on the wire N. In fact if the load is equal on both sides there is practically no current or drop in N. If dynamos are put on the circuit in parallel also—for example, two in parallel on each side of the system, making four dynamos in all, then the machines on each side are managed simply as dynamos in parallel, as previously described. In starting up dynamos on the three-wire system, it is better to start one machine at a time and get that working properly as already described, and then put on a machine on the other side of the system to keep the two sides even. The addition of dynamos in parallel on each side should also be done singly just as on a simple two-wire circuit.

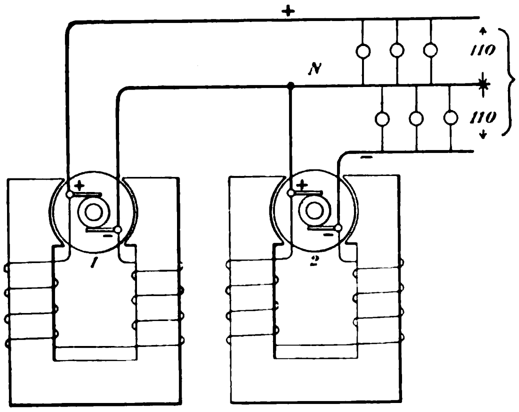


FIG. 16.—THREE WIRE SYSTEM.

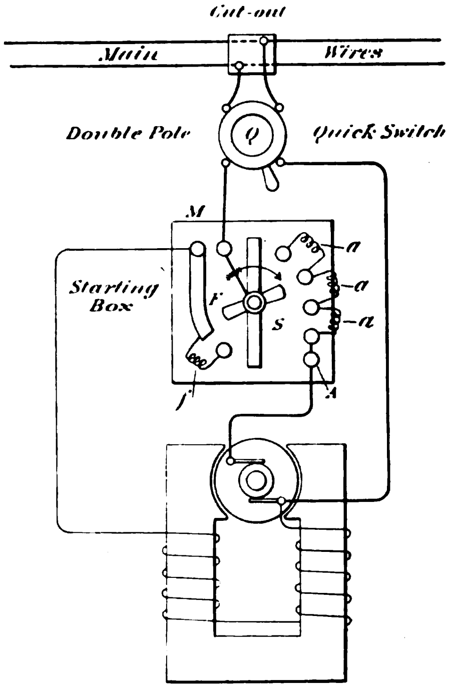

FIG. 17.—SHUNT MOTOR ON CONSTANT POTENTIAL CIRCUIT.

Starting Motors.—The general instructions relating to adjustment of brushes, screws, belt, oil cups, etc., given in the beginning of this chapter should be carefully followed preparatory to starting a motor.

The actual starting of a motor is usually a simple matter since it consists merely in operating a switch, but in each case there are one or more important points to consider.

Constant Potential Motor (Shunt Wound).—A motor, to run at constant speed on a constant potential circuit (a 110-volt incandescent lighting circuit, for example), is usually plain shunt wound. This is the commonest form of stationary motor. The field coils are wound with the right size of wire to take the proper magnetizing current as in the case of a shunt dynamo, and, since the potential is constant, the field strength is constant. Shunt coils must not be used however if the potential is more than 5 per cent. higher, or 20 per cent. lower, than that for which they are intended, as stated elsewhere.

Throwing the field into circuit is therefore simple, but the current in the armature in starting is quite difficult to take care of, because the resistance of the armature is very low in order to get high efficiency and constancy of speed, and the rush of current through it in starting might be ten or more times the normal number of amperes. To prevent this excessive current, motors are started on constant potential circuits through a rheostat or "starting box," containing resistance coils as represented in Fig. 17. The main wires are connected through a branch cut-out (with safety fuses) and preferably also a double-pole quick-break switch Q, to the motor and box as indicated. When the switch Q is closed and the arm S is turned to the right, the field circuit is closed through the contact strip F and the armature circuit is closed through the resistance coils *a*, *a*, *a* which prevent the rush of current referred to. The motor then starts and as its speed rises, it generates a counter E. M. F. so that the arm S can be turned further until all the resistance coils *a*, *a*, *a*, are cut out and the motor is directly connected to the circuit and running at full speed. The arm S should be turned slowly enough to allow the speed and counter E. M. F. to come up as the resistances *a*, *a*, *a* are cut out. The arm S should positively close the field circuit first so that the magnetism reaches its full strength (which takes several seconds) before the armature is connected.

The object of the resistance *f* is explained under "Stopping Motors." The coils *a*, *a*, *a*, are made of fine wire which can only carry the current for a few seconds in a "starting box;" but if the wire is large enough to carry the full current continuously it is called a "regulator" or rheostat because the arm S may be placed so that some of the resistances *a*, *a*, *a*, remain in circuit and they will have the effect of reducing the speed of the motor.

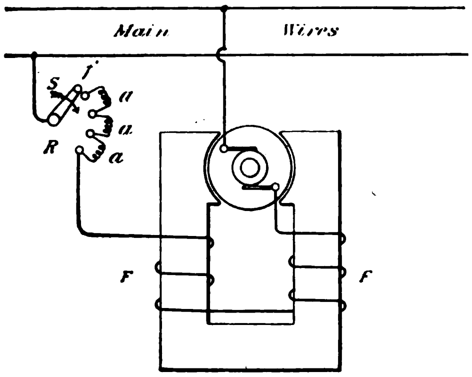

FIG. 18.

Constant Potential Motor (Series Wound).—The ordinary electric railway motor in the 500 volt trolley system is the chief example of this class. Motors for electric elevators and hoists are either of this kind or the previous one. A similar rush of current tends to occur when this type of motor is started as in the case just described, but it is somewhat less because the field coils are in series and their resistance reduces the excess. The essential connections in this case as indicated in Fig. 18, are very simple, the armature, field coils F F, and rheostat, all being in series and carrying the same current. The series wound motor on a constant potential circuit does not have a constant field strength and does not tend to run at constant speed like a shunt motor. In fact it will "race" and tear itself apart if the load is taken off entirely, it is therefore only suited to railway, pump, fan or other work where variable speed is desired and where there is no danger of the load being removed or a belt slipping off.

Constant Potential Motor (Differentially Wound).—This is a shunt wound motor with the addition of a coil of large wire on the field and connected in series with the armature in such a way as to oppose the magnetizing effect of the shunt winding.

It was formerly much used to obtain very constant speed, but it has been found that a plain shunt motor is sufficiently constant for almost all cases. The differential motor has the great disadvantage that, if overloaded, the current in the opposing (series) field coil becomes so great as to kill the field magnetism and the armature slows down or stops and is liable to burn out; whereas a plain shunt motor can increase its power greatly for a minute or so when overloaded and will probably throw off the belt or carry the load until it decreases to the normal amount.

THE RIES REGULATING LAMP SOCKETS.

BY

W. J. Hammer

MUCH has been said of late in reference to the utility of the reaction-coil principle when applied to the regulation of independent incandescent electric lamps operated by alternating currents, as exemplified in the very ingenious, but up to the present, imperfectly understood, regulating sockets recently devised by Mr. Elias .E Ries of Baltimore, and in view of the remarkable claims for this invention and the interest which it has attracted in electrical circles the writer takes pleasure in bringing the matter before the public through the courteous permission of Mr. Ries who has extended to him facilities for making a thorough investigation of its merits. The socket was first shown publicly at the Montreal Convention of the National Electric Light Association, and it is doubtful if any feature of the exhibition at that time attracted more general interest.

Many attempts have been made to produce a satisfactory and economical method of turning down incandescent lamps. The earliest experiments were made by Mr. Edison and others, in which carbon rods, plates, coils of German silver, platinum, iridium and other metals were introduced in the series with the lamp, thus causing considerable of the energy cut out of the lamp to be dissipated as heat, and none of these methods has proved efficient or of commercial value.

Lamps were also constructed containing two or more carbons which could be connected in series or multiple to vary the candle power, and a lamp invented by the writer many years ago contained a number of carbons of various candle power which could be separately introduced into the circuit to give any degree of light desired.

Inventors have also endeavored to construct an economical device for controlling the light without the introduction of resistance, as the value of such a means of regulating the incandescent light has always been appreciated, and one of the principal claims of gas engineers is that the incandescent lamp could not be turned up and down, certainly not with the efficiency which existed in the gas system. Mr. Philip Diebl has presented the writer with a complete set of the experimental steps in his alternating current lamps which show a very interesting stepping-stone in this direction.

Before proceeding further let me say a few words upon the principle of the reaction coil which has been applied in various ways by Thomson, Shallenberger, Ries and others, and referred to in the works of Fleming, Hopkinson and others. A reaction coil of the most simple type is constructed of one coil of a conductor wound around a magnetizable core; probably the simplest form employed commercially is the ordinary spark coil used in electric gas lighting. A direct current passed through such a coil magnetizes the core and sets up lines of force which maintain the same direction so long as the current is continued;

there is a slight heat also produced in the coil due to its ohmic resistance. Naturally, reversing the direction of the current reverses the polarity of the magnetized core. It does more than this, however. This reversal of current and consequent disturbance of the magnetic field produces practically a transformer with but one coil in which appears the impressed E. M. F. and the counter E. M. F.; the counter E. M. F. retards the primary current through the coil, producing the "choking effect" as it is called. In employing a continuous or direct current the counter E. M. F. is produced only at the instant of closing of the circuit or reversing the direction of the current, but with rapid alternating current the counter E. M. F. becomes as constant as the impressed E. M. F. of the primary current, and in the Ries socket the ratio of these may be varied, thus controlling the candle power of each light independently and without resistance, and, as shown by Fleming and others, with an infinitesimal loss.

When the difference between the two E. M. F.'s is greatest, as determined by the position of the regulating key, the light is at its maximum, and when this difference is such that the two E. M. F.'s nearly approximate each other, the filament glows at its minimum point of light. One of these E. M. F.'s being variable with respect to the other, it will thus be seen that lamps of any desired voltage less than that of the supply circuit can be safely burned at their normal candle power, and that standard lamps of any given voltage or resistance that are supplied with a normal E. M. F. of, say, 50 or 55 volts, can be burned at any degree of brilliancy required all the way from a barely perceptible glow up to their maximum candle power. The most remarkable part of this method of electric lighting is its extremely high efficiency and the self-contained simplicity of the apparatus by which it is carried out. The writer has in his possession sockets of this character in which the two E. M. F.'s so nearly balance each other as to extinguish the light without even the necessity of opening the lamp circuit, the amount of energy consumed in maintaining this balance being so slight as to be measurable with only the most sensitive instrument. I have personally placed lamps in series with a sensitive amperemeter and varied the current from 3½ amperes to one-tenth of an ampere as perfectly as gas is turned up and down, the amperemeter indicating the variation in current precisely as if it were a fluid or gas which was being turned on or off.

The writer has had the privilege of witnessing some ingenious and beautiful effects produced by Mr. Ries which show the facility with which this socket lends itself to modifications, adapting it to special requirements. For example, one is enabled to operate a 110-volt Edison lamp on a 55-volt Westinghouse alternating circuit, or to operate a 55-volt lamp on a 110-volt circuit, and at the same time to produce all the variations in light from zero up to full candle power. All this, it should be noted, is produced with practically no loss of current and entirely by the reaction of the current upon itself; no moving apparatus or outside connections whatever, other than the usual circuit adjustments on ordinary lamp sockets being employed.

The Ries socket comprises an enclosing shell of neat design, and but slightly larger than the well-known types of "make-and-break" sockets now in use, and contains a small counter E. M. F. generator or reaction coil, or choking coil, of peculiar construction, which, however, may be of any desired type so long as the general conditions to which it owes its high efficiency are adhered to. This coil consists of a small, thoroughly laminated, closed iron core built up of numerous rings of specially prepared iron, the whole being compressed, taped and wound at one operation with a special silk-insulated cable containing a number of separately insulated copper wires of different diameter, varying according to the maximum current to be carried by each, the ends of these wires, after the cable is wound, being connected in series with each other by contact pins arranged in the path of an arm attached to the operating key. The interior connections are such that when the socket is wired up more or less of the wire composing the coil is in series with the lamp filament, according to the position of the operating key, and the length of wire thus included determines the amount of counter E. M. F. generated. Or, to express it in another way, by cutting out turns of the coil the self-induction is lessened and more current is allowed to flow through the wire to the lamp. The light is divided by this socket into seven different stages, and the potential difference between each contact pin being but one-seventh that of the total difference of potential on the mains, the flashing at these points is very slight, no snap action or other complicated make-and-break mechanism being employed. The entire arrangement is one of great simplicity and compactness, requiring no more attention or knowledge in operation than the turning on and off of an ordinary gas burner, which in this respect it closely resembles.

When the lamp is burning at full candle power, practically all of the coil sections are cut out; that is to say, when lamps of the normal voltage of the supply circuit are used. Usually, however, it is advisable to employ lamps of somewhat lower voltage, so that if for any reason the pressure on the circuit falls below its normal, the lamp may be turned up so as to still give its maximum candle power, a feature not at present attainable with the ordinary type of sockets in general use. When the full amount of light is not needed, the counter E. M. F. generated is increased by the cutting in of additional coil sections, thereby reducing the flow of current through the lamp and causing the latter to glow at a lesser degree of brilliancy, and at the same time materially reducing the strain upon the lamp filament. The winding of the socket is so arranged that when the light is turned down to its lowest stage the filament is just visible in the dark, so as to readily enable one to locate the position of the lamp upon entering a room and to turn it up to the desired point without having to first feel around for it among the electrolier or other fixtures of which it forms part. By the use of this socket one may have some lights in a room burning at low brilliancy and others at a lower degree of incandescence, thus distributing the light exactly where it may be wanted, instead of being compelled to burn the lamps full on when but little light is needed.

The saving in current that this socket is capable of effecting is almost beyond the belief of one who has not tried it, and actually surpasses everything that has yet been claimed for it in this direction. The writer has had occasion to thoroughly investigate this point recently, and has found that a 25 c. p. 50-volt lamp, which consumed 75 watts when burning in one of these sockets at full candle power, consumed, together with the socket, just 3 watts, or only *one twenty-fifth* of the total energy, when burning at a low degree of incandescence equal to that produced by a net potential difference of 10 volts at the lamp terminals. This means that it is possible to burn twenty-five lamps at a visible degree of incandescence by means of this socket with the same amount of electrical energy that a single lamp would consume burning at its normal candle power. Of course, the light given by the lamp at this point, while sufficient to render the filament itself visible at a distance, was altogether too small for the purpose of affording outside illumination, and therefore this cannot be taken as a criterion of the average consumption of current in practice, which would be very much higher, especially as the lamps are usually burned at nearly or full candle power by the consumer when in actual service for furnishing light; the intermediate stages being used for the most part only for all-night service in sleeping apartments and other places where, under the existing condition of things, the incandescent light, if used at all, would be turned off altogether. The writer believes the Ries regulating socket marks a radically new departure in the method of controlling the incandescent electric light.

AMERICA'S PART IN THE DISCOVERY OF MAGNETO-ELECTRICITY—A STUDY OF THE WORK OF FARADAY AND HENRY.—VI.

BY

Mary A. Henry

(*Concluded.*)

STILL something more do we learn from Henry's paper, taken this time in connection with other evidence, in regard to the date of his researches in the induction of electrical currents. This something is very important. The paper closes with what Henry calls "Electrical Self-Induction in a Long Helical Wire," which we have already noticed as constituting the discovery of the "extra current." Now the date of this discovery is exactly fixed for us. Henry, in the *Smithsonian Report* for 1857, p. 106, refers to this identical paragraph, in some testimony in regard to what he did for the telegraph. He says: "I had no idea at the time of abandoning my experiments for the practical application of the telegraph. *Indeed my experiments on the transmission of power to a distance were superseded by the investigation of the remarkable phenomenon, which I had discovered in the course of these experiments, of the induction of a long wire upon itself, and of which I made first mention in a paper in Silliman's Journal in* 1832, *Vol.* XXII;" this paper is the one we are discussing. Notice how distinctly Henry says that "the remarkable phenomenon" was discovered in the course of the "experiments on the transmission of power to a distance." We have only to find these experiments to find our date. They are recorded in *Silliman's Journal* of January 1st, 1831. They were made, as the reader may see if he will find the paper and study it carefully, in 1829, interrupted by the need of the room for the use of the Academy; therefore at the close of the vacation in August, 1829. The discovery of the extra current was made in the course of them, and so is fixed for us its date, viz., 1829.

Copyright in *The Century Magazine*, April, 1888, by THE CENTURY CO.

JOSEPH HENRY.

Another incidental reference Henry makes in the same Smithsonian paper,[1] to the investigations induced by this discovery of the extra current. He says: "After completing the investigations above mentioned" (that is, the experiments upon the transmission of power to a distance) "I commenced a series of experiments upon another branch of electricity." The experiments upon transmission of power to a distance were made, as we have seen, in 1829, in the latter part of the August vacation; this new series which followed them must have been in the vacation of 1830, for only in vacation time could Henry pursue any regular investigation, every day between being filled, as we know, from early morning until night with college duties. There is nothing in Henry's work at this time which can be called "another branch" unless it is magneto-electricity. The brilliant spark of the extra current gave rise to this new series of experiments of 1830, and in this series must have been included the one upon which we have founded our paper. The one phenomenon led to the other, and so we bring again our experiment to 1830, and show also that there were earlier experiments of a like order.

We trust the reader will not forget that the points we have been touching thus one by one are to second the words which fell from the lips of Henry in the happy confidence of home and friendship.

One thing more and we will close our story. We would ask the reader to notice how distinctly in this paragraph about the electrical self-induction in a long helical wire, Henry classes this phenomenon with that of magneto-electricity. Not only does he place them thus together in his paper as of the same order, but later, he writes to Dr. Bache: "I have been much engaged in repeating my experiments on the long and short conductors. The phenomenon, as I suggested in *Silliman's Journal*, is intimately connected with magneto-electricity, if not identically the same. The influence of coiling the conductor I have clearly made out, and can produce with a large coil and one plate of my battery, shocks which may be felt at the elbows. The presence of soft-iron has little effect in producing the spark." And again he writes: "I would infer . . . that effects . . . attributed to magneto-electric action are chiefly due to the reaction on each other of the several spires of the coil which surround the magnet". That the two phenomena are the same, is, as we have said, now recognized by the science of the day. A representative of it says: "The extra current is generated by relative "movement of conductors and lines of force" (the lines "moving in this case). This is precisely the essence of "the great discovery of magneto-electricity, and identically "the principle of the modern dynamo. The great mind of "Henry logically evolved the second from the first, and "recognized their identity. This is shown by the sequence

"in the order of his experiments and published statements. "*The very fact that Henry, at this extremely early date,* "*recognized the relation of these phenomena, produced by* "*the same cause, shows how complete and wonderful was* "*his familiarity with this abstruse subject, so difficult of* "*comprehension even at the present day.*" It is only very recently that the two phenomena have come to be considered the same; the scientific world has only just come to the point where the youthful Henry stood so long ago.

Let us now review our position. *The limit of earliness for Faraday* in the great discovery of magneto-electricity is August 29–30, 1831, when with his ring he is asking the question of Nature. *The limit of lateness for Henry* is August, 1831, since his paper tells us his analogous experiment was made *before* seeing the notice of Faraday of April, 1832; therefore before the close of August, 1831, when Henry's experiments stopped not to be resumed until the following June.

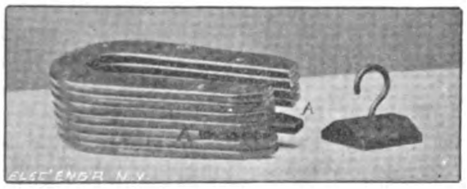
2. Into the very last day of August, 1831, must we squeeze Henry's experiment in order to give Faraday priority, and if at work on that day, which is not probable; *we know he is doing something else*, viz., making a large magnet to pursue on a large scale investigations induced by the discovery which has already been made.

3. The magnet used was the one of 1830, and in 1830 Henry is making a series of similar experiments.

Finally. The especial experiment we have been studying as the initial experiment of the great discovery is hardly so with Henry; it is but the natural sequence of other and earlier investigations. As early as 1829 Henry obtained sparks by what he considers a phenomenon of the same kind.

And so we claim that Faraday cannot in justice be said to have made the great discovery of magneto-electricity until September 24, 1831, more than three weeks after Henry's experiments had ceased; that Henry's magnet asked the great question certainly earlier than Faraday's ring—and to give Henry priority it matters not how much earlier, since it was earlier, that it did so a year earlier, in August, 1830, and that two years earlier, in August, 1829, Henry had obtained sparks from, and recognized a similar phenomenon now declared by science to be the same.

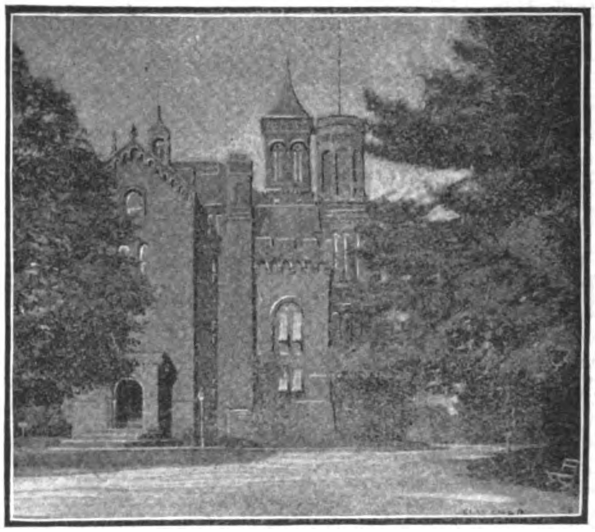
If it seems strange that Henry allowed his valuable discoveries to remain so long unpublished, his busy life should always be remembered. We find him in all his after years equally careless in securing to himself the credit of his labors. In Princeton he had hardly more time than in Albany, and in Washington the world-wide operations of the Smithsonian Institution were even more inimical to scientific research than the duties of college or academy. Recorded in his laboratory books are many researches, never given to the public, for the want of the precious boon of time. Then when the coveted time came, Henry was like the explorer, who fixes his eager eyes on distant hills; more anxious to discover new lands, than to make good his right to those he has passed over. Finally, Henry was of an unusually generous nature. Thought of himself was the last thing to come to him in every action. That he appreciated and valued the credit due him was most natural, but this was far more than secondary to the single steady aim of obtaining new truths from nature that might in some way be of use to the world.



PERMANENT STEEL MAGNET USED BY HENRY IN INDUCING ELECTRICITY. THE COIL WAS WOUND AROUND AN IRON BAR BRIDGING THE POLES OF THE MAGNET AT A. A.

Did Faraday ever acknowledge his indebtedness to Henry's magnet for the part it plays in the great discovery, and later in those other great discoveries of diamagnetism and the magnetic effects on polarized light? A certain general tribute he pays to the magnets, other than their use in his "Experimental Researches," but we cannot think him lacking in appreciation of Henry, since there comes from him the enthusiastic expression:—"Henry is by far the greatest man of science America has produced since the days of Franklin." The two men learned to know and love each other in 1836 when Henry went to London.

Our story is ended; yet for a moment would we ask our readers to turn back to those experiments on a large scale Henry was making in August, 1831. Let us look again at the big "magnet, weighing 101 pounds" with a great "reel" for an armature, wound with a mile of wire, and knowing from Henry's paper that he had found out that merely to move the armature before the poles of the magnet was to produce a current of electricity in the wire; let us also look again, on the same page, at the picture of the modern dynamo, to note its main features, viz., a "big magnet" (Henry's electromagnet unchanged in principle, since he gave it to the world so long ago), and a reel armature, wound with wire, revolving between its poles. It is curious, in those August days of 1831, to see Henry so literally making a dynamo. He had made his smaller magnet, with a wire around its armature, move a needle 40 feet distant; this larger affair was to produce power capable of work; of what kind and extent of work it could be made capable, we in these days know well. Around the room in which he was working were the wires of the telegraph, and in his possession was the first electric motor, a combination made by him of his electromagnet and permanent magnets. With these three prizes in his hands, why did he not leave the Albany Academy and all its arduous duties? There were many reasons, but we give only the one pre-eminent with Henry. He would have had to leave not only the Academy but the great field of original discovery to introduce these things into practical use. The work required for such an undertaking, very different from that of scientific investigation, would have involved years of the time so valuable to Henry. Fortune offered her wealth to the young man if he would, as it were, stop to dig up the gold he had found, instead of seeking further for new treasure, but Henry's answer was, "My ambition is to add to the sum of human knowledge by the discovery of new truths which may be of some use to the world; the practical application of these I desire to leave to others." He might at least have patented his prizes, so as to receive



EASTERN WING, SMITHSONIAN INSTITUTION, WASHINGTON, D. C.

from them some benefit, but when his friends urged him to this his reply was, "What I can give to the world I desire to give freely." The only reward he received for his gifts was the one he desired. At the close of his days he said "I have had a happy life; I hope I have done a little good in it." We have wandered far from the discovery of magneto-electricity, let us return to it and close our story.

A brilliant spark flashes in young Henry's studio in 1829, to betray to him, in the extra current, the secret principle of the dynamo. To-day, this potent instrument enters factory and home, in a thousand ways the effectual slave of man, while tired horses rest in their stables, as it drives our cars to and fro. High up in our city street, when night comes down, the electric spark, leaping from wire to wire, burns a carbon point and turns our darkness into day. The lightning, forced to be man's messenger in the telegraph, compelled to do his work in the electric-motor, has been caught in its free play from cloud to cloud to do this service; even as the steed once coursing in wild freedom over the plain now threads with patient feet the medley of rolling wheels on the pavement below. To tame the intermittent flash into this steady cheering ray, Henry developed the magnetic force, and Faraday and Henry both set electricity and magnetism to work, the one producing the other; but that they can do so anywhere is due to the discovery of Henry, which made it possible to call them into conjunctive action *through any length of wire.* Each year, each month, each day almost, adds some new blessing to the world, through the great discovery of the *identity of electricity and magnetism.* Let England sing her hymn to Faraday; he well deserves it; but let not America forget the meed of praise due her Henry. His is surely not the second place in the great discovery.

STATUE OF JOSEPH HENRY, WASHINGTON, D. C.

THE SEQUENCE

Of Discoveries Connected with and Accompanying the Discovery of Magneto-Electricity.

1829	The making of the powerful intensity magnet, capable of excitation at a distance; the magnet of the telegraph of to-day. The making of the quantity magnet. The discovery of the law embodied in Ohm's theory of the relation between the electric flow and electric resistance. The discovery of the combination rendering possible the telegraph. The making of the first magneto-electric telegraph. *The discovery of, and sparks obtained from, the extra current,* now considered the same phenomenon as that of magneto-electricity.	BY HENRY.
1830	The perfection of the quantity magnet, the stepping stone for both Faraday and Henry in the discovery of magneto-electricity. *The discovery of magneto-electricity.*	BY HENRY.
Aug. 1831	The making of the first electric motor. Experiments on a large scale with magneto-electricity; the making of a dynamo.	BY HENRY.
Aug. 29-30, 1831	Experiment with Henry's magnet in the form of a ring, in which the phenomenon of magneto-electricity was obtained but not fully recognized.	BY FARADAY
Sept. 24th, 1831	Experiment with a bar magnet, viz: *The discovery of magneto-electricity.*	BY FARADAY
Oct. 17th, 1831	Experiment of inserting cylindrical bar into the end of a helix cylinder, usually given in text books as the one by which the discovery of magneto-electricity was made.	BY FARADAY

AN INTERESTING ELECTROLYTIC PHENOMENON.

In a communication recently made to the Académie Royale de Belgique, Prof. Lagrange and M. Paul Hoho describe some experiments made by them on a luminous and calorific phenomenon which takes place under certain conditions when a current is passed through an electrolyte. The phenomenon was first observed in 1844 by Foucault and Fizeau, and has subsequently also been investigated by Righi, Colley, Planté and others. Prof. Lagrange and M. Hoho employed in one experiment a 10 per cent. solution of H_2SO_4, the positive electrode being of copper with 180 square cms. in the liquid, the negative electrode being a copper wire ½ mm in diameter plunged into the electrolyte to a depth of ½ mm. Current was obtained from a battery of accumulators. At first only the ordinary phenomenon of electrolysis are observed; then, as the volts are increased, bubbling and boiling occur at the negative electrode, next intermittent arcs take place between wire and liquid, finally a luminous cylinder is formed having the copper wire for axis, the current then becomes steady, and the resistance very high. On plunging the wire further into the liquid, this series of phenomena can be reproduced. Much the same effects were produced with platinum, zinc, tin, iron, steel and carbon electrodes of different diameters, with sulphuric acid solutions of different strengths, and with a chloride of sodium solution. The production of the luminosity is accompanied by an abnormal resistance which is localized round the negative electrode; with electrodes 29 cms. apart, practically all the fall of potential takes place within 5 mm. of the negative electrode. The shape of the negative electrodes appears to have but little influence. Luminous effects can be made to occur also at the positive, but with some difficulty. It is, however, impossible to produce luminosity at both poles at the same time.

GALVANIZING IN THE COLD.

The London Metallurgical Company are introducing a new process of galvanizing, which seems to have several advantages over the older process. The process appears to be one in which zinc is deposited from its solution in the cold on the wire or sheeting to be coated, and the inventors claim that in this way a more even and uniform thin coating of the protective metal is obtainable, while at the same time, in the case of wire, the tensile strength is not diminished, as occurs when thin iron or steel wires are galvanized by the common methods of steeping in molten zinc. At the ordinary temperature, too, there is no appreciable tendency to form a zinc iron alloy, which causes a considerable waste of zinc in addition to the reduction of strength already pointed out, and may be regarded as a further defect in the present system. Comparative tests on the hardness of the coating on iron sheeting by means of the sclerometer also show that a plate galvanized by this process has a harder surface than that obtained by the ordinary hot method of galvanizing.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, MARCH 9, 1892. No. 201.

Study science with earnestness—search into nature—elicit the truth—reason on it, and reject all which will not stand the closest investigation.—Faraday.

A FEW FIGURES ON UTILIZING NIAGARA.

ONE of the most interesting episodes in connection with the recent Buffalo Convention was the visit to the Hydraulic Power Co.'s works at Niagara Falls. To see the task of making the huge raceway actually in hand was enough to stimulate the enthusiasm of any electrical engineer, and there were not a few members of the party glad to note that there was every possibility of developing a new industrial city near the Falls without in any way spoiling the wondrous natural beauty of the scene. Perhaps there were not a few, also, who were struck with the possibilities of local utilization of all the power derivable, and with the idea that it might be better to have a new Buffalo near the Falls than to try to take part of the Falls to old Buffalo.

It has, in fact, seemed to us that a good deal of the talk about delivering cheap power in Buffalo is rather wild, and likely to do more harm than good to many long-distance projects that have in them larger elements of reality and necessity. We are presented with figures showing that the Niagara Falls Power Co. will deliver power on the spot, at the cataract, at a rate ranging from $10 per h. p. for 5,000 h. p. up to $21 per h. p. for 300 h. p. These figures, however, take no account of current generation, transmission and transformation, all of which have to be added, and for which precedent furnishes very little precise information. But let us for a moment take a few figures on the other extreme of water-power service, and see what it can sometimes cost.

In the reports of the water-power of the United States of the Tenth Census, we find the case of Lawrence, Mass., which was taken up, and the value of which was discussed in a paper read recently by C. T. Main, before the American Society of Mechanical Engineers. Basing his figures on the census report, Mr. Main calculates that the total cost per horse power of developed plant there is $130, which includes an item of $20, due to making the plant large enough to compensate for the fluctuation due to the rise and fall of the river. Deducting this amount, therefore, in order to cover a case where the water supply is uniform, we have $110 as the cost per horse power for a fall such as we find at Lawrence.

Now, a good steam plant in 500 h. p. units can be installed for $65 per horse power, so that the ratio in favor of steam there is about two to three. The operating expenses for both cases is given by Mr. Main at $13.70 in the case of water and $21.80 in the case of steam per horse power per annum. But to the figure given for water must be added the cost of steam, or equivalent plant, for heating the buildings in winter, which is taken as equal to one-fifth of that required for steam power, and the expense of maintaining it. This item, when added, brings the cost of the maintenance of the water plant up to $19.13 per horse power per annum; that is, slightly under that of steam; but, as will be noted, with a far greater original outlay.

In the case of Lawrence, Mass., cited above, objection might be made that the cost of power given was too high. While it is true that in some cases the cost of water power in this country is lower than given, yet, on the other hand, not a few cases can be cited in which it is considerably higher, reaching in some cases as high as $25, so that we believe the case cited is a good one for the argument we are making, and that the figure will hold.

At the Buffalo Convention, some data from the Oerlikon Works was cited to show how inexpensive the electrical part of the work would be. For instance, "the cheapest kind of a line" would suffice to carry 25,000 volts for 22 miles! We beg to differ most emphatically. A summer holiday trial in a quiet region of Germany is no test of the average conditions obtaining for six months of the year, along the storm-swept, exposed southeastern shore of Lake Erie. So far from the "cheapest kind of a line" sufficing, Prof. Elihu Thomson seems to have his doubts of everything short of a first-class oil pipe line with special methods of insulation between pipes and conductor. Moreover, the figure is given of only $36 per horse power for the generating and transforming plant. If it is secured for twice that, even on large units, the promoters will be doing pretty well. The cost of the Frankfort-Lauffen plant was about $285 per effective horse power, in the ratio, it is stated, of $46 to $49 per horse power for the apparatus and $236 per horse power for the line.

It is said, and with truth, that these figures are high. But there needs an enormous cutting down in investment and maintenance before this power can be delivered and distributed in Buffalo to compete with the steam now manufactured there at about $35 per horse power. We are personally very much inclined to believe with Mr. William

Stanley, Jr.—no mean authority on this subject—that most, if not all, of the power will be used around Niagara Falls. It will certainly be cheap at that point, and its utilization there with the aid of electricity will still be one of the great engineering feats of the century. People talk gabble about using the power of Niagara in New York City. It is vastly more within the bounds of likelihood that we shall have to drink the water of Lake Erie instead of running our factories with it.

HIGH AND LOW SPEED ENGINES IN ELECTRIC RAILWAY WORK.

Our readers who have been following the discussions appearing in our columns on the best type and size of engine to be employed in central stations will find much food for thought in the results of a test carried out at the power station of the East Cleveland Railroad Co. by Mr. Chas. W. Wason. The tests are of all the more value for the purposes of comparison, as both the high and low speed engines are of the single cylinder type, working non-condensing and representing standard types of construction. In view of the diversity of opinion which still exists as to the merits of the two types tested, it must be considered as remarkable that the consumption of coal and water was so nearly identical in both cases, with, however, a very slight difference apparently in favor of the low speed engine. In drawing conclusions from these tests it would be well, however, to bear in mind that electric railway work is of such a variable character that the highest economy with either type of engine is not attainable, so that it would be unwise to generalize from these tests as to the economy of engines of either type employed in electrical work of a more uniform character. While these tests are of unquestioned value, the record requires to be still further amplified by a test of low speed direct-connected engines and of condensing engines of both types. We believe that American electric railway power stations embody examples of every one of these types, and some concerted action for the purpose of carrying out tests appears to be not only possible but timely.

MUNICIPAL LIGHTING PLANTS.

Discussion of the question of municipal ownership and operation of street lighting plants has recently assumed some prominence again in the daily press and otherwise. One of the most absurd contributions to the discussion that has come to our notice is to be found in a paper by Michael A. Mikkelsen, Johns Hopkins University, printed and circulated by the American Academy of Political and Social Science, Philadelphia, under the title "Electric Street Lighting in Chicago." It is absurd as failing to notice items of cost that should be patent to any person assuming to write upon an economic subject. Because the annual cost per arc light, in the Chicago municipal system, is stated to be $68, while Boston pays private corporations, according to Mr. Mikkelsen, $237.25, [the correct figure for Boston is $146, as given in report of Lamp Department,] he concludes that Chicago is effecting a large saving, and implies that municipal ownership is a manifest advantage. Mr. Mikkelsen omits to mention that interest, taxes and depreciation are not taken into account in the cost per light of the Chicago system. He gives the outlay "for organization and maintenance" to the date of his paper (which date nowhere appears) as $556,000. This we take to be cost of the plant.

Reported cost per year of service, 900 lamps @ $68.	$61,200
Add interest and taxes on $556,000, say 6 per cent.	33,360
Depreciation " " say 5 per cent......	27,800
	$122,360

Or $135.96 per lamp, more than double Mr. Mikkelsen's figures.

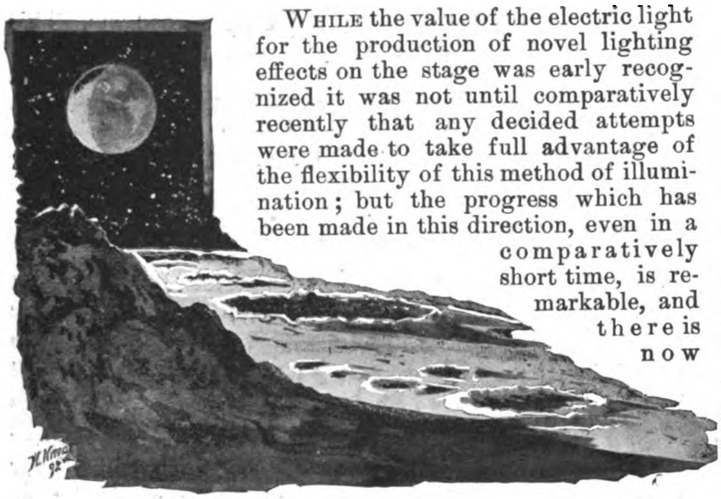
The above takes no note of water rates or of certain salaries, over and above the operating force, which we understand should be properly included. It has been stated that the actual cost to the city of Chicago, when all legitimate charges are included in the reckoning, is not less than $190 per lamp per year. It is somewhat suggestive in this regard that the Chicago Arc Light and Power Company has recently tendered for lighting a district of the city not yet equipped by the municipality at $182.50.

The question of public advantage as between municipal and private ownership of lighting plants is one that should be considered on a less partisan basis, and with less heat than hitherto, with more candor and a wider inclusiveness of the facts upon which it depends. *A priori* reasoning will not settle it. The objections to municipal ownership are obvious enough in view of the general conduct of public works, as to both cost and efficiency in our large cities. Its possible advantage can be shown only by the production of a complete service record, and an inclusive and unquestioned accounting of the operations of a considerable number of city plants.

POLYPHASE MOTORS IN AMERICA.

The claims which individuals and nations make for inventions of great merit are frequently apt to be obscured owing to a lack of proper understanding of the points at issue while often, in addition thereto, the records available are not drawn upon. We think this is exemplified in a marked degree by the controversy which has arisen as to the inventorship of the three-phase alternating motor as employed in the Lauffen-Frankfort experiments. Mr. Tesla early laid down the broad principle of the rotating field, employing currents of different phase, and described in his patents methods of operating at 90 and 60 degrees phase difference. The later substitution of one name for another to designate the same principle, evidently does not constitute invention, so that Mr. Tesla must be conceded to be the originator of the polyphase alternating motor system. But it is a matter of additional importance to know that such motors were first operated in this country and that, as described by Mr. Albert Schmid, on another page, a three-phase alternator has been in commercial operation for some time past. Mr. Schmid also shows that the work on this type of motors has steadily advanced, and that Tesla machines of no less than 1,000 h. p. are now commercially available. It is evident that we have at hand already in this country apparatus for the heaviest work in long-distance transmission that is likely to come up, not excluding the magnificent schemes for harnessing and distributing Niagara.

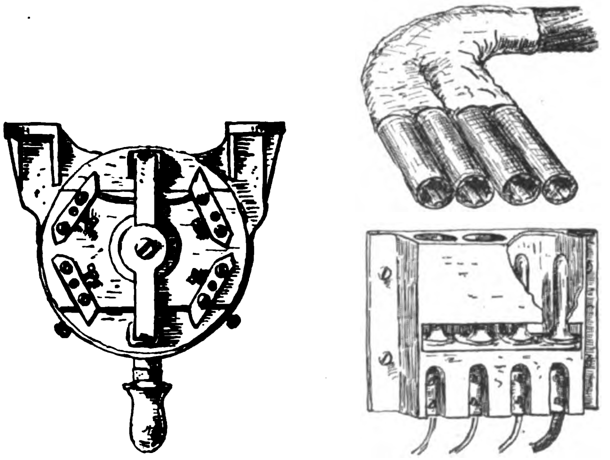
ELECTRIC LIGHTING ON THE "URANIA" THEATRE STAGE.



While the value of the electric light for the production of novel lighting effects on the stage was early recognized it was not until comparatively recently that any decided attempts were made to take full advantage of the flexibility of this method of illumination; but the progress which has been made in this direction, even in a comparatively short time, is remarkable, and there is now no character of stage lighting work, even the most complex, which cannot be effected electrically.

The perfection to which stage lighting has arrived is admirably exemplified in the methods employed in the production of the scientific performance entitled "A Trip to the Moon," which is now being produced at the Scientific Theatre "Urania" at the Carnegie Music Hall in this city —a performance we would strongly advise all our local readers to see. The apparatus and methods here employed were designed by Mr. J. C. Mayrhofer, electrical engineer, of New York, and consist of 850 incandescent lamps of 24 c. p., each operating at 110 volts and including a system of five arc lamps taking 12 amperes each, intended for sciopticon illumination.

One of the most important pieces of apparatus employed is the stage regulator, illustrated in Fig. 1, which was specially constructed for this purpose by Siemens & Halske, of Berlin, and which is arranged for eight circuits and for three changes of color in each circuit. The board is seven feet high and has a base three feet by two, and is so arranged that every possible shade of color can be obtained, together with every variation in strength of the light. The blue, red and white colors are produced by lamps having bulbs of corresponding color and are switched on independently, by means of the switches shown in the four vertical rows. The construction of these 24 switches is shown in Fig. 2. By turning the handle to the left the full current is turned on to the lamps, while turning to the right throws in the full resistance and practically extinguishes them. For every group of lights there is, in addition, a rheostat, which is placed in the base of the regulator as shown, and each group is controlled by one of the switches on the horizontal board. Each resistance is graduated into 68 steps, and the switches are so arranged that two groups, of different colors, can be regulated simultaneously.



Figs. 2, 3 and 4.

Mr. Mayrhofer has designed a special arrangement of the sciopticon illumination for reproducing the sun and moon and their eclipses, using the arc light for this purpose. The apparatus employed consists of a system of achromatic lenses, which in this instance, owing to lack of room, are placed three or four feet behind the transparency forming the background of the scene and which throw the light upon the transparency in an intense beam of exceedingly sharp outline. In the representation of the eclipses of the sun and the moon a number of sciopticons are employed simultaneously, the beam of light from one sciopticon completely covering that of the other.

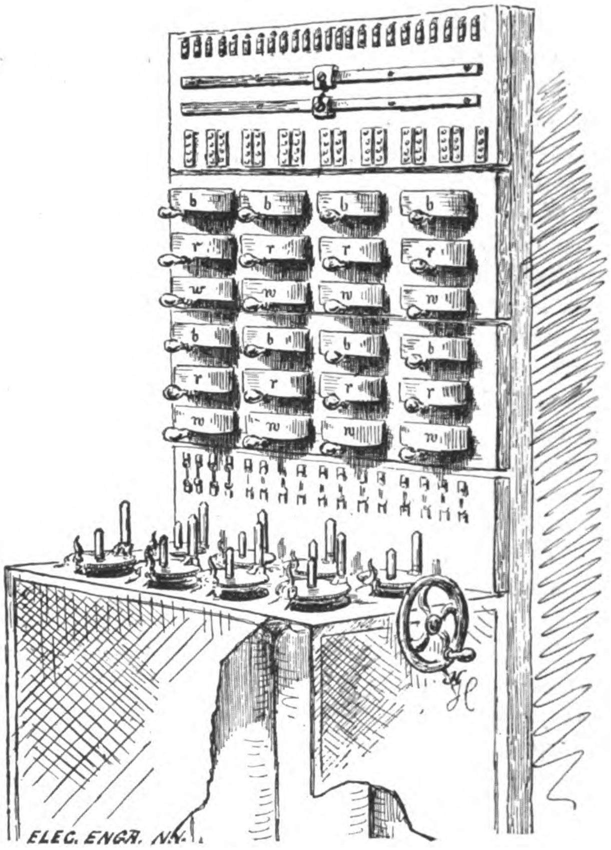


Fig. 1.—Stage Regulator.

The reflection of the heavenly bodies on the surface of water, and the imitation of waves is also produced by the projecting apparatus, by means of three glass plates having a wave-like picture upon them and which are progressively rotated in front of the lenses by means of a clockwork and an eccentric lever. This arrangement is entirely new and exceedingly effective.

Among the other novel forms of apparatus which are brought into play in the scientific theatre are a rail and slide apparatus, as well as the portable cable connection and stage pockets. The former are so constructed that all the ecliptic and parabolic curves which the heavenly bodies traverse or describe in their orbits can be reproduced, a problem which evidently required the highest skill in the application of stage mechanism. The portable connection apparatus is illustrated in Figs. 3 and 4. The connection between the stage regulator and the stage pockets is permanent each having four circuits and the groups of lamps are connected to these stage pockets by four-conductor cables with socket terminals, as shown in Fig. 4. This connection is a very simple one and is specially adapted for traveling theatrical companies.

In order to reduce the number of lamps required Mr. Mayrhofer employs colored lamps of large candle power, so that a smaller number of lamps suffices to give the desired illumination. This is a departure from the methods heretofore employed but the results have shown it to be an eminently wise one.

THE GAS BATTERY AS AN ACCUMULATOR.

BY

W. M. Stine

THE article in a recent number of THE ELECTRICAL ENGINEER on "A Combined Accumulator and Gas Battery," by Mr. F. A. La Roche, recalls to the writer some results obtained during a somewhat similar series of investigations pursued a year ago. Though differing in details they appear to have a direct bearing on the experiments above referred to.

At that time my experiments were simply preliminary to a series I am still at work upon. Though the data obtained are still incomplete, they possess so much interest for me that I am anxious to see the matter thoroughly worked out. Pressing routine duties leave no time for the present for their further prosecution, and I give my results in the hope that they may be of some value to other workers in this field and may perhaps contain some suggestions for them. I present them as an abstract from a paper on "Some Forms of Carbon Storage Batteries," which was read before the Physical Section of the American Association for the Advancement of Science at the Washington meeting last August.

The ideal in designing accumulators is to obtain maximum output with minimum weight. It is preferable to have this energy delivered at a reasonably high voltage per cell, with intensity, rather than simply quantity of chemical action; necessitating fewer cells for a given purpose. This ideal storage is doubtless that which would result from the decomposition of water on charging, with the subsequent reunion of the H and O on discharge. In the formation of water from the constituent gases more energy is liberated than in any other practical chemical reaction. Such a battery would develop a high voltage and store the most energy for a given current, while the mass of matter involved in the chemical reaction would be the least possible for an ampere of current. All this is clearly demonstrated in the gas batteries of Grove and others. It is, however, acknowledged to be impossible to reduce this ideal battery to a practical working form, for the reason that gases act in such cases only in solution.

In a series of investigations made by the writer it became necessary to employ a modification of this type of battery, and a modified form of the carbon electrode was used. The high absorptive power of finely-divided carbon for gases was utilized. Well-burned animal charcoal was treated with acid to dissolve out the mineral matter, and then thoroughly washed and dried at a high temperature to expel all gases absorbed by it. This dried mass was moistened with a 40 per cent. (by weight) solution of sulphuric acid and packed in small battery tumblers around the porous cups which were also filled with the same mixture. Plain arc carbons were heated and inserted for the electrodes, and so connected as to make the carbon in the porous cup positive. A current of one ampere was generally employed in charging and the potential carefully noted by a voltmeter.

A noticeable feature of these cells was the rapidity with which they acted with a very small charge. The first charge was continued for five minutes and they behaved quietly and without gasing, except at the water-line if made too moist. Such charges usually developed voltages ranging from .9 to 1.4 volt. They were then discharged through an electric bell, to determine relative efficiency. As an audible voltmeter, a bell possesses some merit.

The first five-minute charge given to a cell would usually ring the bell for nine minutes, and this increased by use to from 15 to 25 minutes. Increasing the time of charge showed that the cell reached its limit of economical capacity in about ten minutes, when the voltage became 1.7 to 1.9. When pushed beyond this the cells would gas badly, though the voltage increased slowly and in some cases reached 2.79 volts.

The stability of the charge was, however, low. While standing charged for an hour the voltage decreased considerably, and the decrease was more marked during the first hour following the charge than subsequently. But the output in watts was but slightly lower than when discharged at once. This greater immediate activity of the cells is doubtless due, to a great extent, to the amount of gas still remaining in solution; and the decrease upon standing must have been caused by the progressive absorption of the gases by the carbon, thus taking them out of solution and thereby increasing the internal resistance.

The cells were frequently allowed to remain charged for 12 hours and occasionally the charge had almost entirely disappeared by the end of this period. This was accounted for, in part, by the appearance of the oxygen, or positive electrode, when withdrawn from the cell; it was invariably eaten and furrowed. In one case where the cell had been in use for some time, the electrode was found reduced to the thickness of a lead pencil. It resembled the worn zinc from a Leclanché cell, and the carbon appeared to have been consumed rather than simply disintegrated. The hydrogen or negative electrode in no case showed signs of corrosion, except where, by change of polarity, it had been positive. This oxidation of the carbon finally led to an abandonment of the experiments.

Though convinced that a gas battery, pure and simple, is not practicable, yet the idea of combining it with an accumulator is an excellent one, and should be successful. If, instead of combining the gas battery and the accumulator in a single cell, the gases were led through pipes into another cell, where they would be kept separated by such a device as Mr. La Roche used, this gas cell could be connected in parallel with the accumulator and the energy lost by gasing almost completely restored. Were the gas cell to contain some absorbent substance in connection with a liquid, it would appear to yield better results. It is possible that the oxidation of carbon and the increasing internal resistance which occurred during my experiments would not take place under the high pressures here employed.

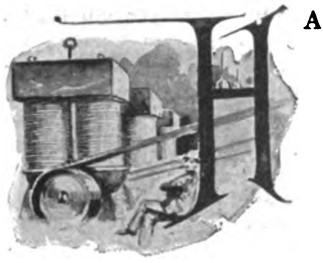
While charging, this gas cell could be thrown out of circuit and then, when connected in parallel, the two cells would form branches of a divided circuit, each containing its own E. M. F. It is evident that dynamic equilibrium would be maintained even to complete discharge. There would be some loss due to heating owing to difference of E. M. F. between the branches.

OHIO UNIVERSITY, ATHENS, OHIO.

THE MAGNETIC PROPERTIES OF OXYGEN.

COMMENTING on Prof. Dewar's recent experimental verification of the magnetic properties possessed by liquid oxygen, M. Guillaume points out in *L'Industrie Electrique* that if we accept the values found by Edmond Becquerel for the magnetic constant of oxygen, it ought, when in the liquid state, and in a field of medium strength, to possess a magnetic moment per cubic centimetre, one-third of that of iron, and a magnetic moment per gramme twice as great as that of iron; so that the strange conclusion is forced upon us that oxygen is the most magnetic of substances.

THE ELECTRIC PLANT AT THE VIRGINIUS MINES, OURAY, COL.



HARDLY a more striking example of the manner in which water-power developed at the foot of a mountain can be utilized at its lofty summit can be found than in the large plant which has been installed by the Edison General Electric Co. at the Virginius group of mines near Ouray, Colorado. It is one of the largest purely mining plants, if not the largest, in the world. Every difficulty likely to be met with in work of this nature was encountered in the installation. The pipe line is laid along the side of a rocky cañon; the wires from the power house to the mine are strung partly through dense timber, where they are exposed to damage from falling trees and partly above timber line, over rocks and snow banks, where the poles and wires are liable to be carried away by snow-slides and where lightning storms are frequent and violent. The line is nearly four miles long, the voltage of the current 800 volts, and the mine is wet. The relative advantages of the ground return and complete metallic circuit are illustrated, and switches are so arranged that either may be employed, the metallic circuit being used at present. The plant includes a variety of machinery, comprising two pumps, one hoist, one blower, and two motors running mills, indeed, almost everything except locomotives and drills, and these will probably be added shortly. Lastly the enormous saving that can be effected in many places by the utilization and transmission of water-power by means of electricity is strikingly manifested. Coal at the mines costs $18 per ton, and before the installation of this plant was made, the cost of the power amounted to nearly $40,000 per annum. This sum is largely saved by the adoption of electric power. An instance is also afforded of unprofitable mines being rendered profitable by the use of cheaper power, for while some of the mines in this group are rich enough in metal to repay working under the most

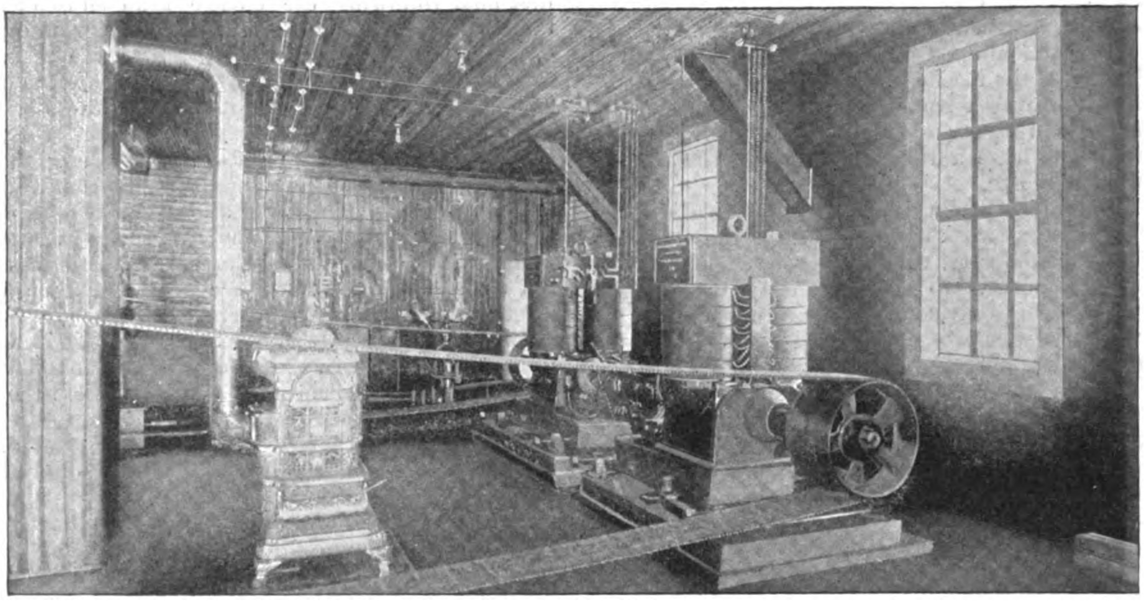


FIG. 1.—INTERIOR OF VIRGINIUS MINES POWER HOUSE, NEAR OURAY, COL.

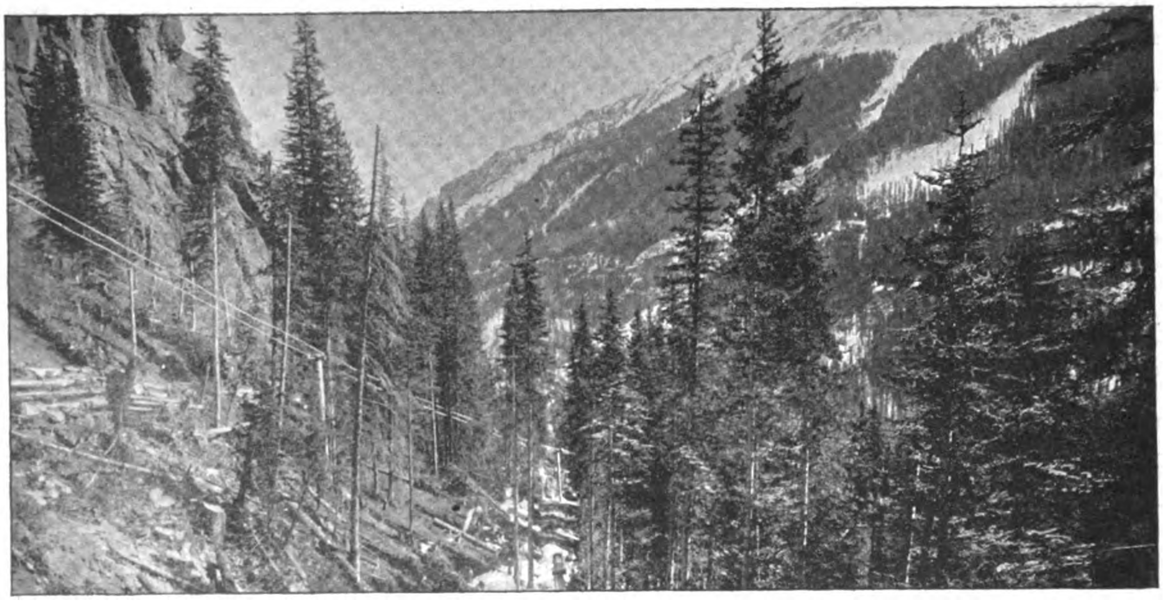

FIG. 3.—VIRGINIUS PLANT, LINE THROUGH TIMBER: ALTITUDE 9,000 TO 10,000 FEET.

adverse conditions, there are others of lower grade which would have been shut down in case the electric plant had proved a failure, but which, with the plant, will now yield a satisfactory profit.

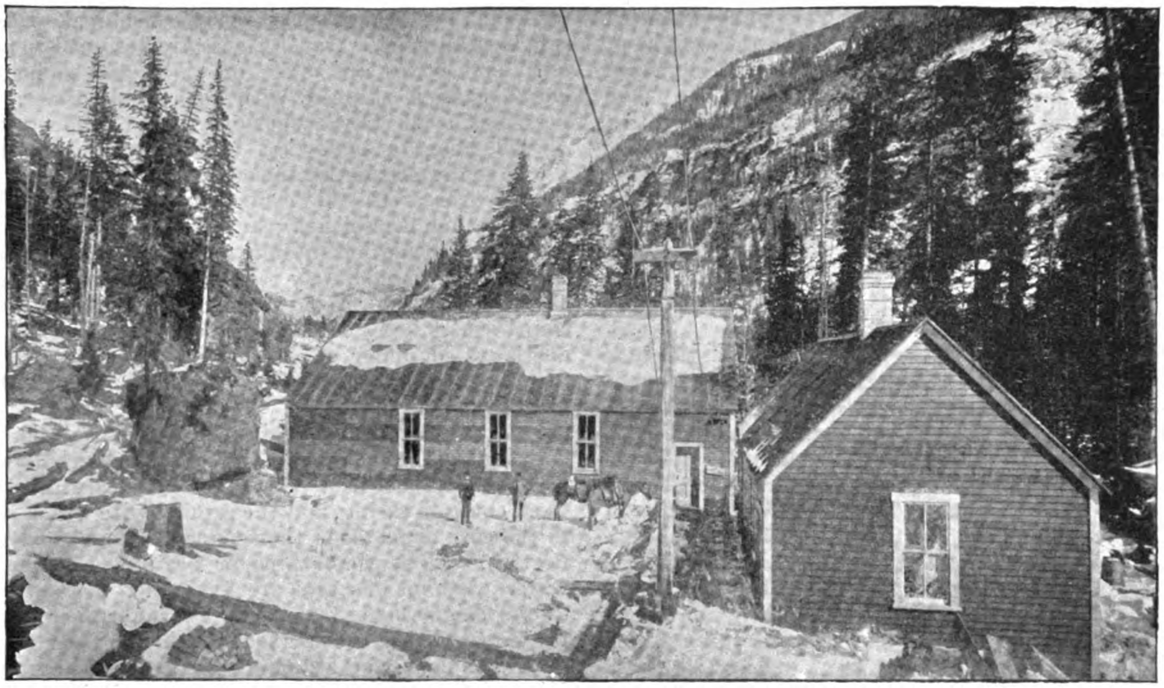

Fig. 2.—Power House; Electric Plant, Virginius Mines, Col., Altitude 9,000 Feet.

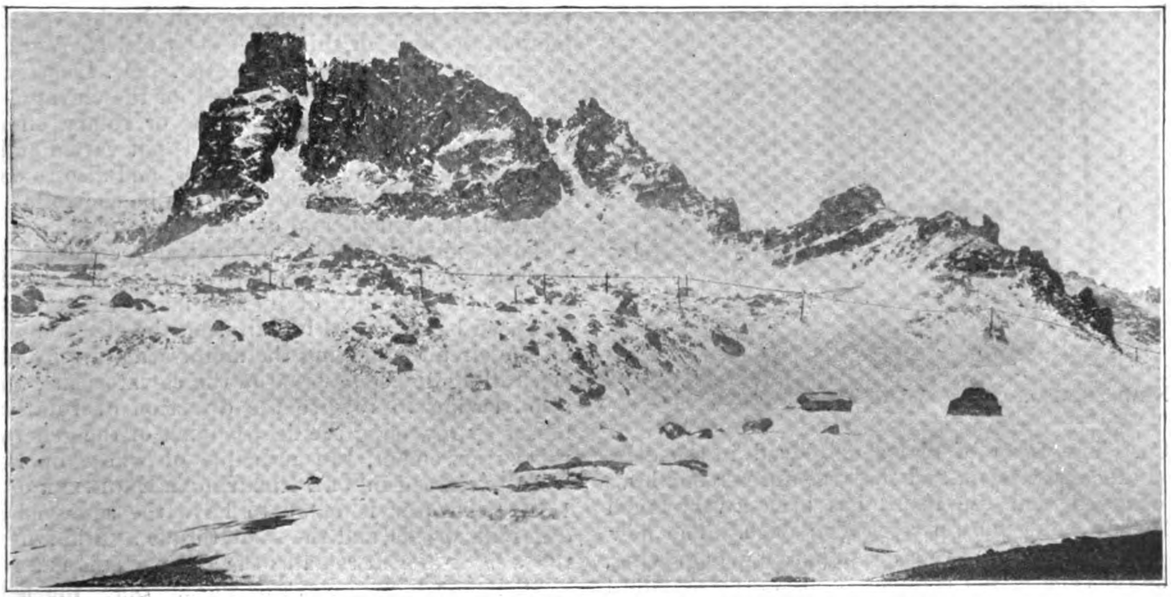

Fig. 4.—Line Across Snow Plateau: Altitude 12,500 Feet.

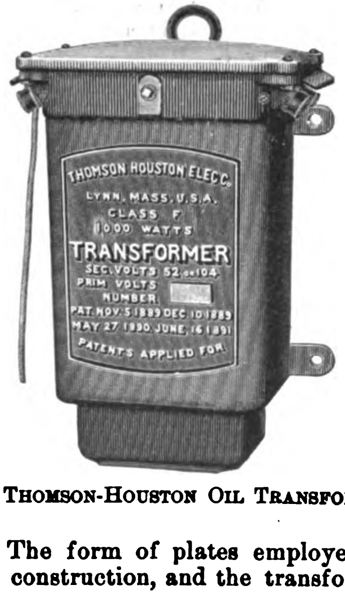
If a careful search of the Rocky Mountain region had been made with a view of selecting for the first extensive experimental mining plant, a location presenting every conceivable difficulty and which would prove a crucial test to electric power at the very outset, it is very probable that the Virginius Mine would have been chosen. The Virginius and neighboring mines, owned by the Caroline Mining Company, are situated near the summit of Mt. Sneffles, in the region of perpetual snow, at an almost inaccessible altitude of 12,700 feet above the sea and about 5,000 feet higher than the timber line. The water power utilized for the plant is in Red Cañon Creek, nearly four miles from the mines. The water-power plant consists of a small dam, and iron pipe line, extending along the side of the cañon, a distance of about 4,000 feet, giving an effective head of 485 feet, and two Pelton wheels, one 5 feet, the other 6 feet, in diameter, capable of developing under that head 500 h. p. and 720 h. p. respectively, or a total of 1,220 h. p., the two wheels being connected to separate shafts, so that either wheel may run the entire station. The electric generating plant comprises, at present, one 100 K. W. Edison dynamo and two 60 K. W. Edison dynamos, giving a total output of 295 e. h. p. The length of the line, as previously described, is a little over 19,000 feet. The electric machinery operated at the mines consists at present of two pumps, of 60 h. p. and 25 h. p., respectively, one hoist (25 h. p.), two Edison motors, each of 60 h. p. running concentrators and stamping mills and a 15 h. p. blower. The large pump which was erected when the plant was first installed, raises 150 gallons of water, 700 feet per minute, and is of the Knowles duplex type. An Edison standard motor is geared to it by a double worm, one right hand and one left hand, working into two spur-gears that mesh into each other and operate the pump, the object of the two worms being to neutralize the longitudinal thrust. The smaller pump, which was installed a few months ago, is somewhat similar, the motor, however, being mounted over the pump, with its armature vertical, the weight of the armature counteracting the thrust of the single worm employed. Both pumps have been working steadily and smoothly for several months, and have satisfactorily filled requirements.

The hoist consists of an Edison motor of standard type, but of street car winding and controlling switch, geared to the drum through the medium of a friction clutch. By means of the controlling switch and clutch, the hoist is under more perfect control than a steam hoist. The motors for the mills and blowers are of the standard type, and present no exceptional features.

The most serious troubles have been caused by lightning, electric storms in that section of the country being frequent and very violent. This has formed the subject-matter of particular study and special lightning arresters have been devised that give excellent protection. Since their adoption little or no trouble has been experienced from this source. That difficulties were encountered in the early operation of the plant is not surprising, and the fact that these difficulties have been overcome and the entire plant is operated successfully and satisfactorily under conditions that for severity are not likely to be exceeded anywhere, demonstrates the practicability of electric power for mining, and guarantees its success in this field.

THE NEW THOMSON-HOUSTON OIL TRANSFORMERS.

A radical departure in the manufacture of transformers has been recently taken by the Thomson-Houston Electric Co. The form of plates employed in the core, the method of construction, and the transformer box have all been changed, and the result has been a very much higher efficiency and a more perfect regulation. The new transformer, illustrated in the accompanying engraving, is known as the type F, and is manufactured in six standard sizes, ranging from 12 to 150 lights capacity.



New Thomson-Houston Oil Transformer.

One of the radical changes in the new type is the banishing of all fuses from the transformer box. For the primary circuits there has been designed a special combination of switch and fuse, which is in an iron box and which may be placed where convenient in the neighborhood of the transformer which it protects. By avoiding fuses within the transformer it becomes possible to seal the boxes hermetically after they are once in position, something which of course cannot be done when it is necessary to open the transformer at intervals on account of a blown cut-out.

A perfect and permanent insulation of the primary coil from the secondary coil, and both from the core, is a matter which has been very seriously considered, with the result that all type F transformers are designed to operate in oil. The boxes are made oil tight, and sufficient oil in closed cans is shipped with each transformer. The oil possesses some advantages over the paraffine usually employed, being a somewhat better insulating medium and filling the interstices of the coils more closely.

By reason of the oil insulation, the liability to burn out is very much diminished ; and even in case of a puncturing of the insulation by lightning or by other severe strain, the break is immediately re-insulated and the destruction of the transformer avoided. In the manufacture of the transformers great care is taken in the insulation, and each one is tested under a pressure of 5,000 volts alternating (equivalent to about 9,000 volts direct) before the introduction of the fluid.

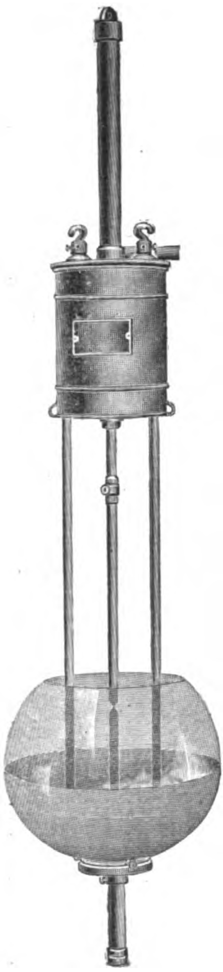
Another safeguard against loss of insulation between primary and secondary is added by the grounding of the core. The sheet-iron plates are very carefully insulated from the iron casing, and the ground wire which is attached to the core or plates is then connected to a good earth connection, such as water pipe or gas pipe. Where neither water pipe nor gas pipe are available, a good earth conductor can be made by placing a large copper or iron plate far enough below the surface to be in damp earth, imbedded in broken coke, and attaching the ground wire to the plate. With the core grounded in this way, a lightning discharge reaching it is conducted to the earth by the grounding wire, and the points at which the discharge took place are immediately re-insulated by the oil in the transformer.

LEONARD'S METHOD OF OPERATING ELECTRIC ELEVATORS.

The operation of elevators or the lifting of variable weights by means of electric motors involves problems met with in perhaps no other work to which electricity is applied, and hence our readers will be interested in the method devised for this purpose by Mr. H. Ward Leonard, of this city, and recently patented. Mr. Leonard's objects are mainly to enable the speed of the elevator-car to be varied without varying the torque or rotary effect of its armature so long as the weight is not varied and without varying the efficiency of the motor, and also to enable the speed and direction of movement to be controlled from the car itself in a simple and convenient manner.

To accomplish this he mechanically connects the operating motor with the elevator-car and connects the motor so that the strength of its field-magnet remains constant, its speed being varied by altering the electromotive force on the circuit supplying the motor-armature by means of a controlling device situated in the elevator-car ; this device also serving to reverse the direction of rotation of the motor by reversing the field magnet of the generator. By this arrangement, the principle of whose operation was fully explained in The Electrical Engineer of Nov. 25, 1891, the motor is made to have the same efficiency at different speeds and the same torque at different speeds if the weight moved remains the same. This is a feature of great importance in elevator work. Since the field is kept at a constant strength, no sparking occurs at the commutator-brushes, for the non-sparking point does not change materially. The reversal of the electromotive force is accomplished at a time when the same is at a minimum, and to reverse the motor the electromotive force of the supplying generator is first gradually reduced to a minimum point, then reversed, and then gradually raised to the point desired.

THE GRAVES LOW TENSION ARC LAMP.



Graves Lamp.

The Graves low tension arc lamp shown in the accompanying illustration, is the invention of Mr. W. D. Graves, of Cleveland, O., who has made the subject of arc lighting a special study for the last ten years, and has brought out many improvements in the arc lamp.

This illustration shows his very latest improvement and it not only embodies all the desirable features of his former lamp, but contains many that are peculiar to itself. This lamp does not contain any clock-work, dash-pots or complicated sets of springs, and the adjustment of the lamp is simple. The same winding answers for any desired quantity of current from four to twenty amperes, with very little adjustment of the mechanism. Thus it is obvious that a change in current or variation in potential affects the light far less than usual.

The carbons are held in suspension by mechanical means and thus a uniform length of arc is secured at all times, and the feeding is simply done by the shunt circuit. The clutch is very simple and will allow for greater variation in the size of the rod than is usually the case with corresponding freedom from wear. Should it become worn to such a degree that it does not work perfectly, it can be replaced by a new one very readily and at a very little cost.

The lamps are at the present time working with good results on 110, 220 and 500 volt circuits and also on $6\frac{1}{2}$, 8, $9\frac{6}{10}$, 10 and 18 ampere circuits. From this it will be seen that the lamp is adapted to any standard currents and can be used either on a multiple system, or in series, and in order to do this, it is not necessary to add any complicated mechanism to gain the desired results.

The designer of this lamp has arranged the construction to meet the convenience of both the trimmer and the repairer, making it possible for any ordinary workman to take it apart, clean, assemble and adjust it in the shortest possible time. All the screws and threads are standard, so that should any part become broken, it is not necessary to send to the factory for special screws or parts.

The lamp when constructed for constant current circuit is provided with two positive automatic cut-outs, and when the carbons are consumed, the lamp is cut out through no resistance, and thus saves the power required to run the lamp when burning and makes it practically impossible to burn out the coils or any other part of the lamp.

THE DEVELOPMENT OF ELECTRIC TANNING.

According to *La Lumière Electrique* several French tanners have adopted the electric tanning process, but have not made the fact public "for fear of displeasing a clientèle always distrustful of new methods." The Société Brion et Dupré is known to employ six drums, capable of an annual output of 600 tons of tanned hide. In Portugal there are two electric tanneries at work, at Porte and Braga, having an annual output of 700 tons of tanned hide; and in Madagascar an electric plant is being set up. In Brazil, at Boa Vista, some eight miles from Rio de Janeiro, there is an electric tannery covering about 13 acres, and possessing no less than 100 drums. The annual output of the Boa Vista plant will ultimately be about 70,000 tons.

STAGE LIGHTING BY ELECTRICITY.

BY

Dr. Graham Scott

Few theatre-goers realize the lavish expenditures on light which managers are obliged to make in order to present a realistic stage picture.

The calcium light is most commonly used for stage work, though attempts have been made to substitute cheaper illuminants, such as magnesium, zirconium, and carburetted hydrogen, or illuminating gas. None of these being adequate to the demands, however, attention has been turned to electricity, which promises to meet the requirements made upon it.

Developments have recently been made in this line by the Scott Electric Co., of New York. In some of the European theatres ordinary arc lamps of from six to ten amperes have been used, but in them the fault has been that the candle power obtained from so small a light is insufficient to admit of the screening or "toning" necessary to diffuse and overcome the violent glare of electric light. They have been, in most cases, obtained from street circuits of a potential too high to be safely handled. The Scott lamp is adapted to constant potential circuits of low voltages and is self-focussing. A current of from 12 to 20 amperes at a potential of 50 volts is usually supplied, giving from 2,000 to 5,000 c. p. against 900 to 1,200 c. p., the maximum of the calcium light.

There are many advantages to be gained by electric lighting. First, and perhaps the most important, is the instantaneous control which the operator obtains over any number of circuits however widely distributed, allowing the production of effects which with calcium would be impossible.

Second, a much stronger light can be produced and regulated than with calcium, and, with the aid of filterers to diffuse it, richer and more mellow effects can be obtained. By the use of a lens, greater accuracy is secured in focussing than is possible with a calcium light.

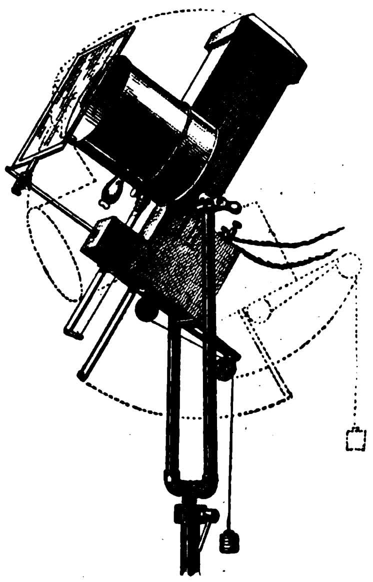


Fig. 1.—The Scott Lens Box for Electric Stage Lighting.

Lastly, yet of most importance, is the greatly reduced cost of electric lighting, for the actual results show that an improved quality of light can be furnished at one-fifth the cost of any other. In many of the prominent theatres of New York, Chicago, St. Louis, and other leading American cities this apparatus has been introduced with gratifying results.

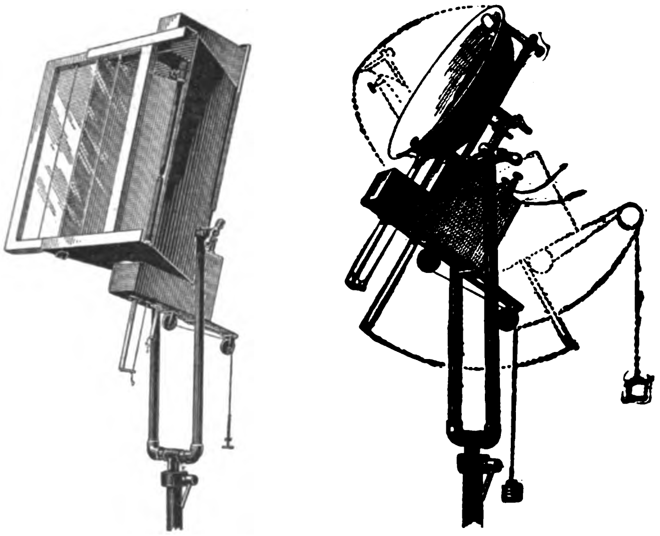
The accompanying illustrations show the electro-calcium lamp now in use. Its form is such that all the usual appliances, such as the lens box, Fig. 1, the color box, Fig. 2, or the reflector, Fig. 3, can be used as readily as with the calcium light. It will be noticed that the lamp can be placed at any angle, from below the horizontal to the vertical, and has a lateral range of motion that includes a complete circle. The electro-calcium apparatus is so compact and thoroughly mechanical in construction that many theatrical companies carry an outfit of from two to fifteen lamps, etc., on the road.

The flexible wires, pockets, switches and rheostats can be put up on stage and gallery in a few minutes, and if the electric current can be spared (as it can in most instances, each electro-calcium lamp taking the equivalent of only 30 16 c. p. incandescent lamps), it is but the work of a moment to couple the main connecting wire and series of necessary cut-outs and plugs with the electro-calcium outfit.

If the dynamo of the theatre is run to full capacity, it is always very easy to make arrangements with some outside electric company to run the necessary main wire to the theatre to operate the requisite number of electro-calciums.

The Edison Illuminating Co., of San Francisco, ran a wire in this way from their station to the Baldwin Theatre—about 2,500 feet—for Mr. David Henderson's "Crystal Slipper" company when performing there about a year ago. This company carried 15 of the Scott electro-calcium lamps on the road.

Mr. Henderson's "Sinbad" company is now carrying 18 of the electro-calciums on the road. The lighting of "Sinbad" is the most brilliant and gorgeous ever seen in the history of stage illumination. This gentleman is the first theatrical manager of the country to use the electro-calcium apparatus manufactured by the Scott Electrical Co., and with the able assistance of Mr. Martin Krueger, his electrician, has demonstrated to the theatrical world the uses and possibilities of electricity for stage lighting.



FIGS. 2 AND 3.—COLOR BOX AND REFLECTOR.

"Sinbad," with all the magnificent electro-calcium lighting effects, will be presented at the Garden Theatre, in this city, during the coming summer season.

Stuart Robson carries two electro-calciums on the road, and his manager, Mr. John Wooderson, and himself express themselves as perfectly satisfied with the apparatus.

Messrs. Richardson and Colby, managers for Francis Wilson, state that the company will save several thousand dollars during the season of 40 weeks by using the eight electro-calciums instead of the old style lime lights, for which they paid between $5,000 and $6,000 per season.

A COMPARATIVE TEST OF HIGH AND LOW SPEED ENGINES IN RAILWAY WORK.[1]

BY CHAS. W. WASON.

HAVING high speed and Corliss engines in our power house, I thought it of sufficient interest to make some comparative tests relative to the economy of the two types of engines. A brief description of our plant may not be out of place. Three Armington & Sims engines 14½ x 15 inches and three others 18½ x 18 inches of the same make, compose the high speed portion of our power plant. To each small engine are belted two Edison generators of 40,000 watts capacity and to each large engine are belted two 80,000 watt generators, manufactured by the same company. In the other part are two 28 x 48 inch simple Corliss engines made by the C. & G. Cooper Co., belted to countershaft, 7 inches in diameter and about 80 feet long with four clutch pulleys 88 inches in diameter by 28 inches in face made by the Hill Clutch Company, and from the countershaft are belted four 175,000 watt Edison generators. Our steam plant consists of 14 tubular boilers, 18 feet long, 72 inches in diameter with 72 4-inch tubes with Murphy settings. We have been able to use the same boilers in each test selecting those that would equalize the distance the steam was carried in each test.

Laboring under the disadvantage of not having an ampere meter of sufficient capacity to carry the entire current, we were obliged to station a man to read the individual amperemeters of each machine, they taking the amperes upon the sounding of a gong every 15 seconds. The water used for steam passing through a meter, it was an easy matter to determine the quality used during the 10 hours. Each wheelbarrow of coal thrown on the floor was weighed, so that we know the number of tons burned. An accurate account of the number of motor and tow cars moved and mileage made by each was kept. Hourly readings of the thermometer, and condition of the weather were noted. We used a Bristol automatic steam registering gauge. The temperature of the water as it left the Berryman heaters was taken every 15 minutes, also as it ran from the street main.

By taking readings of the quantity and pressure of current every 15 seconds, or in other words 2,400 readings in 10 hours, a very fair average of the electrical output has been obtained. Owing to the constant and rapidly varying load it is almost impossible to get the mechanical horse power. In taking a card with the indicator the load will change before the stroke is completed. I would very much like to hear from any one who has a device that will accomplish this purpose. I expected to find a greater difference in favor of the low speed over the high speed; of course, we have the countershaft to run in the former which load does not come in on the latter, giving in turn a factor of flexibility that is of much importance.

The following is the data of tests taken Feb. 14th, with high speed, and Feb. 21st, with slow speed plant:

1892.	Feb. 14th. high-speed engines.	Feb. 21st. Slow-speed engines.
Average elec. horse power developed in 10 hours	563	630
Maximum elec. horse power developed in 10 hours.	813	842
Minimum elec. horse power developed in 10 hours	486	354
Number gallons oil used in 10 hours	7 gal.	8 gal.
Water consumption for 10 hours	3,900 cu. ft.	3,800 cu. ft.
Water consump. per aver. elec. horse-power per hour.	43.29	37.69
Water evaporated per lb. coal per hour	6.61 lbs.	6.51 lbs.
Amount of bituminous slack coal used in 10 hours	36,900 lbs.	36,300 lbs.
Amount of ashes made in 10 hours	4,890 lbs.	4,779 lbs.
Amount of fuel used per aver. elec. h. p. per hour	6.55 lbs.	5.76 lbs.
Pounds of comb. used per aver. elec. h. p. per hour	5.68 lbs.	5.00 lbs.
Number of pounds of coal per car mile	6.57 lbs.	6.38 lbs.
Average amperes per 10 hours	812	907
Maximum amperes per 10 hours	1,120	1,160
Minimum amperes per 10 hours	720	720
Average voltage per 10 hours	518	518
Maximum voltage per 10 hours	535	530
Minimum voltage per 10 hours	505	510
Number of readings of 15 seconds intervals	2,385	2,395
Average temperature of water from heaters	186° F.	197° F.
Average temperature of water from street main	39° F.	39° F.
Average temperature of the outside atmosphere	43° F.	41° F.
Condition of weather	rainy.	foggy.
Average steam pressure as per automatic steam registering diagram	96 lbs.	97 lbs.
Maximum steam pressure as per registering diagram.	102 lbs.	100 lbs.
Minimum steam pressure as per registering diagram.	90 lbs.	90 lbs.
Average chimney draught	⅞ lbs.	15/16 lbs.
Number motor cars run on line[1]	62	62
Number tow cars run on line	9	10
Number miles made by motor cars	4,640.02	4,627.29
Number miles made by tow cars	767.65	806.53
Number passengers carried on cars	12,366	15,463
Number miles made by Brooklyn motor cars	61.75	87.28
Number miles made by Brooklyn tow cars	30.87	43.64
Number miles by Broadway motor cars	117.10	117.10
Number of Brooklyn motor cars	4	4
Number of Brooklyn tow cars	2	2
Number of Broadway motor cars	5	5
Number of Broadway tow cars	None.	None.
Total number of motor car miles	4,818.87	4,831.77
Total number of tow car miles	798.52	850.17
Total number of motor cars	71	71
Total number of tow cars	11	12
Total number of motor and tow cars	82	83
Total number of car miles made from power developed	5,617.39	5,681.94
Average horse power per car	6.86 h. p.	7.59 h. p.

[1] Fifty-four of these are No. 6, and seven are No. 14 Edison, with one T.-H. S. R. G. of 15 h. p.

Undoubtedly more data could be obtained (and more comparisons made; however, the above may prove a starter for others who are working in this unexplored field.

---

[1] A paper read before the Cleveland, Ohio, Electric Club, March 1, 1892.

ACCUMULATOR CARS IN PARIS.

WHAT is termed the first serious trial of accumulator cars in Paris is reported as about to be made by the Société des Tramways de Paris et du Department de la Seine. If the experiment is successful, other companies propose to adopt the system, whilst new lines for the construction of which concessions have been granted will probably be similarly equipped. The first line of the Paris Company on this method is to be in operation between Saint

Denis and the Madeleine, and the cars are to attain a speed of 7½ miles an hour normally in Paris, 10 miles outside the fortifications, and 22 miles an hour if necessary! The cars to be used may be characterized as locomotives, as they will only contain the storage batteries, the motors and the driving mechanism. This type of car is the patent of the firm of G. Averly, of Lyons, and each axle is fitted with a motor of 15 h. p. The motors are of the Gramme or Siemens type. The cells are of the Laurent-Cély-Sarcia make. One of the peculiar features of the cars is the arrangement of mechanism which permits of their being derailed and placed on the line again as may be desired. The cars, which will shortly be put into service, are provided with electric brakes, and the weight of one locomotive with two trailing cars is 12 tons.

ON THE LAW OF HYSTERESIS.—V.

BY CHARLES PROTEUS STEINMETZ.

Cast-Steel, Annealed and Hardened.—Of one kind of steel, two test pieces were cast, at the same casting, turned off to standard size and, by comparing them in the magnetometer, found to be exactly alike. Then the one piece was hardened, the other left annealed. Magnetometer tests gave the following magnetic cycles:

TABLE VII.

	Hardened.		*Annealed.*		
	I	II	III	I	II
Maximum M. M. F., in Ampereturns: F =	44.5	65.5	108.0	44.5	101.0
Maximum magnetization B =	8,500	11,400	13,500	14,100	16,600

Herefrom as coefficient of hysteresis, was found

$$\eta = \underbrace{.02494 \mid .02512 \mid .02490}_{} \mid \underbrace{.007997 \mid .007962}_{}$$

Average, $\eta = .024987 \sim .025$ $\eta = .007980 \sim .0080$

Hence, when *annealed*, the hysteretic loss is $H = .008\, B^{1.6}$; when *hardened* $H = .025\, B^{1.6}$; and calculated by means of these formulas, we derive

$$\underset{\text{calc.}}{H} = 48{,}400 \quad 77{,}500 \quad 101{,}500 \quad 34{,}730 \quad 45{,}100$$

and

$$\underset{\text{calc.}}{H} - \underset{\text{obs.}}{H} = +100 \quad -300 \quad +400 \quad -70 \quad +100$$

$$= \text{per cent. of } \underset{\text{calc.}}{H} \quad +.2 \quad -.4 \quad +.4 \quad -.2 \quad +.2$$

It is especially interesting to note that though the chemical constitution of both samples is exactly the same, their magnetic behavior is entirely different, so that the *magnetic* properties of iron seem to be determined much more by its *physical* than its *chemical* constitution.

Another sample of cast steel of low magnetic conductivity gave the results shown in Table VIII.

TABLE VIII.

	I	II	III	IV
Maximum M. M. F.: F =	37.0	52.0	75.0	95.0
Maximum magnetization: B =	6,380	7,640	8,950	10,000

Average, $\eta = .001195$, *i. e.*, $\sim .012$

Herefrom, $H = .012\, B^{1.6}$

$$\underset{\text{calc.}}{H} = \quad 14{,}620 \quad 19{,}520 \quad 25{,}140 \quad 30{,}020$$

$$\underset{\text{calc.}}{H} - \underset{\text{obs.}}{H} \quad +20 \quad -380 \quad +140 \quad +420$$

Maximum magnetization: B =	6,800	10,300

Average, $\eta = .01616$; $\underset{\text{calc.}}{H} = \quad 23{,}000 \quad 42{,}800$

$$\underset{\text{calc.}}{H} - \underset{\text{obs.}}{H} = \quad -300 \quad +800$$

$$= \text{per cent.,} \quad -1.5 \quad +1.9$$

Magnetic Iron Ore.—In the following, Table XI. are given the magnetic characteristics of a piece of magnetic iron ore, apparently pure Fe_3O_4 of the dimensions, 1 in. × 1 in. × $2\frac{11}{16}$ in.

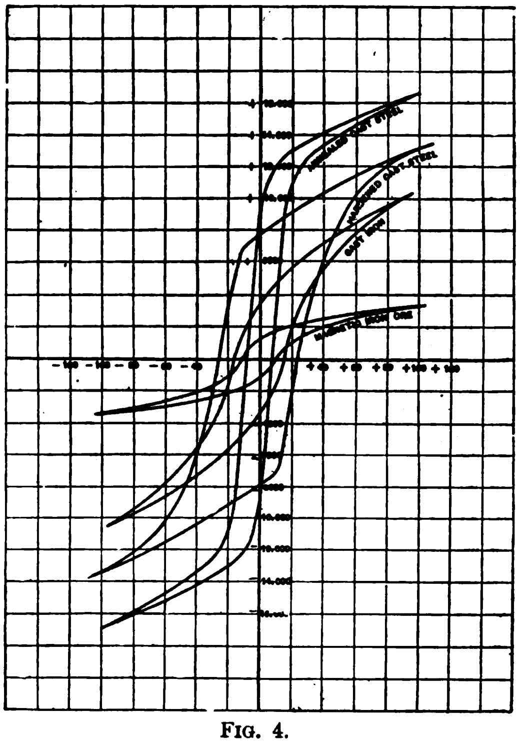

FIG. 4.

TABLE XI.

MAGNETIC CHARACTERISTIC.

F in ampere turns per centimetre length of magnetic circuit.
B in lines of magnetic force per square centimetre.

F	B	F	B	F	B
10	750	70	2930	140	3770
20	1510	80	3080	160	3930
30	2000	90	3220	180	4070
40	2320	100	3350	200	4200
50	2560	110	3470	220	4310
60	2760	120	3580	240	4400

TABLE XII.

CYCLIC MAGNETIZATION.

	I.		II.			III.	
F	B_r	B_d	B_r	B_d	F	B_r	B_d
0	± 900		±1020		130	3640	3740
10	0	+1520	− 200	+1660	140	3730	3820
20	+1200	1920	+1000	2020	150	3820	3900
30	1800	2230	1750	2280	160	3910	3980
40	2160	2500	2150	2520	170	3990	4050
50	2450	2700	2390	2710	180	4050	4110
60	2670	2850	2610	2880	190	4120	4170
70	2850	3000	2800	3020	200	4190	4230
80	3020	3120	2980	3150	210	4250	4280
90	3190	3250	3140	3280	220	4320	4340
100	3340	3360	3280	3410	230	4360	4370
110	3440		3410	3530	240	4400	
120	(106.)		3530	3640		(240.)	

$$\underset{\text{obs.}}{H} = 9{,}840 \text{ ergs}, \qquad 13{,}780 \text{ ergs};$$

$$\eta = .02049 \qquad .02041; \text{ Average}, \eta = .02045$$

Curve of hysteresis, $H = .02045\, B^{1.6}$

$$\underset{\text{calc.}}{H} = 9{,}820 \text{ ergs} \qquad 13{,}810 \text{ ergs}$$

$$\underset{\text{calc.}}{H} - \underset{\text{obs.}}{H} = -20 \text{ ergs} \qquad +30 \text{ ergs}$$

$$= -.2 \text{ per cent.} \qquad +.2 \text{ per cent.}$$

As seen, the coefficient of hysteresis of magnetic iron ore, $\eta = .020$, ranges between that of cast-iron, $\eta = .016$, and of hardened steel, $\eta = .025$. The magnetic conductivity is approximately 20 per cent. of that of wrought iron.

In Fig. 4 is given a comparison of the hysteretic curves of hardened steel, annealed steel, cast-iron, magnetic iron ore. This figure shows well the three characteristic forms of hysteretic curves:

TABLE XI A.

$$H = \eta B^{1.6} [+ \varepsilon N B^2]$$

H in ergs per cycle and cm.^{3}, B in lines of magnetic force per cm.^{2}, F in ampere turns per cm.

Material.	Hysteretic Coefficient. η	Magnetization at the M. M. F. $F = 40$	Residual magnetism R. For $F = 40$	Coercitive force C. For $F = 40$
Very soft iron wire (Ewing)...........	.0020	14700		(1.5)
Westinghouse converter, sheet-iron...	.0024	17800		(1.8)
Very thin sheet-iron, standard.......	.0030 [1]	17100		(2.3)
Thick sheet-iron.........................	.00333[2]	17500		(2.5)

Magnetic iron ore..........................	.02045	2320		

1 For $N = 100$. 2, $\varepsilon = .746 \times 10^{-6}$. 3, $\varepsilon = .2083 \times 10^{-6}$. 4, $\varepsilon = 1.16 \times 10^{-6}$.

(*To be continued.*)

Obituary.

AUGUSTUS CLASON GRAHAM.

WITH profound regret, we have to announce the death, under peculiarly afflictive circumstances, of the founder and first editor of this journal, Augustus Clason Graham, which took place early on the morning of Thursday, February 18th. After returning from a visit to the bereaved family of his brother, James Varnum Graham, who died in Flushing, L. I., on Wednesday, Mr. Graham was so prostrated with grief that he succumbed to a sudden attack of apoplexy, and passed away only a few hours later.

Mr. Graham was descended from an old and distinguished Colonial family, who traced their ancestry to the noted Scottish chieftain Græme, the historical hero of the Highlands. His father, John Lorimer Graham, was formerly postmaster of New York, and in his day a prominent citizen. Augustus Graham was born February 22, 1828, and received a good education in the best schools of the city. In 1849 he joined a party of fifty gold-seekers, who sought to reach California by ascending the Rio Grande. Before they had proceeded many days' journey, they were attacked by epidemic cholera in a malignant form, and in a few hours scarcely half a dozen remained alive. Mr. Graham took command of the remnant, and after unparalleled hardships, ultimately reached New Orleans, with two others, being the only survivors of the ill-fated expedition.

It is not too much to affirm that no more enterprising, public-spirited, generous and philanthropic citizen than Mr. Graham ever won the respect and esteem of the community in which his lot was cast. Of an eminently social disposition, and kind-hearted almost to a fault, he led the citizens in all good works, while the poor and needy found in him the best and most constant of friends. He always took a lively and abiding interest in all literary and educational matters, and for fifteen years prior to his decease had been the treasurer and most active member of the Board of Education of Whitestone, N. Y., his place of residence.

In January, 1881, in conjunction with Mr. C. B. Williams, he established *The Electrician*, of which he assumed the editorial and general management, the business department being in charge of Mr. Williams. This was the first essay which had been made in this country to establish a journal on broad lines, embracing the entire field of the electrical industries. The new journal took a high position from the start, and its cordial reception by those interested in the then rapidly growing electrical developments soon led the managers of other journals, which had already established themselves as exponents of the telegraphic, telephonic and other special interests, to enter the same field. Comprehending at once the new requirements of the situation, Mr. Graham associated with himself Mr. Franklin L. Pope, in the editorial conduct of his enterprise. The journal was at once enlarged and greatly improved in many ways; a broad, independent and vigorous editorial policy was marked out, which has been consistently adhered to from that day to this, and under its new title of *The Electrician and Electrical Engineer*, subsequently shortened to the THE ELECTRICAL ENGINEER, it entered at once upon an uninterrupted career of prosperity. Ultimately, seeking to withdraw from the cares of active business, Mr. Graham disposed of his interest to his associates, but it has been a gratification to them to feel that he has never ceased to manifest the warmest interest in the success and prosperity of the journal, to which his own intelligent conceptions and high ideals in earlier days contributed no unimportant share.

Mr. Graham leaves a widow and two children to mourn his untimely death.

EUGENE T. LYNCH, JR.

A GREAT many of our readers will be inexpressibly pained and grieved at the death in Memphis, Tenn., of Eugene T. Lynch, Jr., by a fall from his horse. From his active connection with the old United States Electric Lighting Co. in this city, young Mr. Lynch was well known to a very large circle in the electrical field. He served as an officer of both the National Electric Light Association and the New York Electric Club, and took a leading part in their affairs until recently, when he was tempted South by the large opportunities in electric railway work and the demand for electric lighting. As electrical engineer and contractor, he installed several plants, and was busy with a number of projects at the moment of his sad and untimely death.

Legal Notes.

LITIGATION IN THE FIELD OF INTERIOR WIRING.

THE growing importance and value of methods of interior wiring, combined with the spread of a well-founded conviction that before long nearly every interior wire for electric lighting will be run through tubes, has naturally led to litigation with regard to patents on interior conduiting, and there is promise already of a struggle for the possession and control of what must eventually be an enormously valuable field of work. The Interior Conduit and Insulation Company having announced its intention to maintain the claims it has made to a practical monopoly, both in fundamental principles and in detail devices, trouble has been taken to secure from it a statement as to the patents on which its case is based:

No. 176,784. Issued to Edward A. Hill, May 2, 1876.

Claims in combination a series of electric circuits, a series of inclosing tubes with occasional breaks giving access to wires from the surface of floors, walls, etc.

No. 343,087. Issued to L. Stieringer and J. H. Vail, June 1, 1886.

Claim in combination main and branch circuits in combination with distributing centres for interior electric lighting.

No. 401,498. Issued to Edward H. Johnson and E. T. Greenfield, April 16, 1890.

Claims the use of an insulating tube in a system of interior conduits in combination with the two wires of a circuit in one tube. Also a system of tubes consisting of mains, branches, etc., continuous from source of supply to points of consumption, except as intersected by switches, cut-outs, etc.

No. 469,208. Issued to E. T. Greenfield, Feb. 16, 1892.

Claims the same as above except that it covers the use of two tubes, each enclosing a single wire of a circuit.

Many minor details demanded in the practical working-out of a conduit system are also said to be fully covered by these and other patents, but the four patents above mentioned are considered ample to establish the company's contentions as to the following exclusive patent rights:

To employ a system of tubes for interior electric lighting.

To employ a system of electrical distribution in which a main circuit supplies a number of branches.

To employ a system of tubes in which the two wires of a circuit are placed in a single tube.

To employ a system of tubes in which there is a tube for each wire of a circuit.

With regard to the above we are informed that the Interior Conduit & Insulation Co. has secured an injunction against the Holtzer-Cabot Electric Co. under the patents mentioned above.

On the other hand, suit for injunction and accounting has been brought against Grace, Pinkham and Godfrey, who may be said to stand for the Interior Conduit Co., by the Indurated Fibre Industries Co., and the Builders' Insulating Tube Co. for infringement of what is known as the McMahon patent, covering the making of pipes, or paper tubing, to carry electric wires. The plaintiffs also announce their intention to bring suit against users. In the above suit, a demurrer has been filed on the part of the plaintiffs, which demurrer calls in question the validity of the McMahon patent. Argument is now awaited. The plaintiffs are making a paper tube called "Buildite."

A further aspect to the situation is given by the action of the New York Insulated Wire Co., the manufacturers of the "Vulca" composite duct. Their attitude in this triangular fight may be inferred from the following notice they have given out during the past week as to their claims:

First—We were the pioneers in advocating the system of single wires in conduits and demonstrating the "Duplex" or double conductors unreliable and dangerous.

Second—That the "Vulca" electrical wire ducts will stand the action of cements, plaster, acids, etc.

Third—We guarantee our customers absolute protection against all suits for infringements in using our Vulca wire ducts and complete system for interior wiring.

The above summarizes the situation, so far as any steps have been taken to enforce rights or determine them in this new and important field of work.

ANOTHER DOUBLE CARBON LAMP INJUNCTION.

JUDGE SHIPMAN of the United States Circuit Court, in this city, handed down, on March 1, his opinion in the suit of the Brush Electric Company against the United States Electric Lighting Company. The suit turned on the use of the "double carbon lamp." The Brush Company claimed the exclusive right to use this device under a patent granted Sept. 2, 1879.

Judge Shipman upholds this claim, and grants a perpetual injunction against the United States Company restraining that corporation from using the "double carbon" in the future. The defendant is also required to appear before United States Commissioner Shields to render an accounting of profits made on the use of the disputed patent in the past two years.

Patent Notes.

OPERATING CONVERTERS IN PARALLEL—THE STANLEY PATENT.

A PATENT relating to electrical distribution by alternating currents issued on March 1st, to the Westinghouse Company, as assignee of William Stanley, Jr., appears to have a very important bearing on the art as now practised in this country. The history of this patent is a somewhat remarkable one. In October, 1885, Mr. Westinghouse having previously secured an option to purchase the American rights of Gaulard and Gibbs for the original alternating system, which as then operated in London, had the converters arranged in series, like arc lamps, employed Mr. Stanley to make an experimental investigation of the system, with a view of adapting it to the requirements of the electric lighting service in this country. He took possession of an old disused factory in a secluded locality in Great Barrington, Mass., and commenced his labors. A descriptive paper written by him dated November 26, 1885, shows that he had at that early date become fully possessed of the idea that the converter must be so constructed that the counter E. M. F. opposing the impressed E. M. F. would vary in direct proportion to the variation in resistance and flow of current in the secondary circuit, and that to accomplish this it was necessary to use endless cores in the converters, and to connect them in multiple, all of which was a radical departure from the theories of Gaulard and Gibbs, but which has been abundantly proven to be the correct practice. By March, 1886, Stanley had completed a small plant and lighted up a number of buildings in Great Barrington at a considerable distance from the station, this demonstration being the earliest example of the practical use of the multiple arc self-regulating system of alternating distribution. About a year after this a small plant was erected by Marmaduke M. M. Slattery for the Sun Electric Company, of Woburn, Mass., which was in all essential particulars identical with that of Stanley. It had converters with endless cores placed in multiple arc, and was constructed with the same ratio of voltage, in primary and secondary circuits, and the same ratio of iron to copper in the converters, coincidences which were claimed in behalf of Stanley not to have been altogether accidental. The able and ingenious attorney who had charge of Mr. Slattery's interests, filed on April 5, 1888, an application for a patent, broadly covering in all its essential features a system of multiple-arc distribution so constructed and proportioned as automatically to maintain a correspondence between the number of lamps alight and the load on the dynamo. Immediately after the issue of this patent, No. 386,936, July 31, 1888, Mr. Stanley, by way of protecting the interests of the Westinghouse Company, filed an application covering exactly the same ground and making the same claims. A vigorously contested and protracted litigation ensued before the Patent Office lasting several years, which has been finally terminated by the decision of the Commissioner in favor of Stanley, resulting in the issue of his patent. Meantime, Slattery's interests had passed into the control of the Fort Wayne Company, and thence into that of the Thomson-Houston Company. The virtual effect of the Commissioner's decision and the issue of a patent to Stanley will be to render the Slattery patent void. As all multiple-arc alternating plants necessarily employ the construction and mode of operation covered by the Stanley patent, the indications are that the effect of the patent upon the relative strategic positions of the leading competitors now in the electric lighting field will be by no means an unimportant one.

Personal.

MR. FRANK SILLIMAN, one of the staff of the engineering department of the Thomson-Houston Electric Company, was one day last week presented with a handsome testimonial from the members of the same staff on the occasion of his marriage and departure to Savannah, Ga., where he has gone to accept an important appointment. The testimonial consisted of a dozen silver and pearl fruit knives, and a very handsome silver calendar, and was presented by Mr. W. J. Button, in a few appropriate words. The following gentlemen, members of the engineering staff, of the railway, lighting and international departments, were the donors: A. Jaastad, M. T. Kahurl, F. E. Greenwood, C. L. Howes, W. J. Button, H. W. Adams, G. D. Norton, J. F. Dubois, J. H. Watterman, A. Chandler, F. P. White and W. A. Chapman.

MR. ROBB MAC KIE, for the past two years electrical engineer of the Allied Electric Light Companies of Cincinnati, has resigned that position to establish an office as consulting engineer in that city. Mr. MacKie was formerly general superintendent of the Fort Wayne Electric Company and is widely and favorably known in the profession. He was elected a member of the National Electric Light Association at the recent Buffalo meeting. His long and varied experience in practical electrics fit him peculiarly for the occupation he has adopted.

DR. LOUIS BELL, who has been editor of *The Electrical World* for a little less than two years, has resigned, and will hereafter have no connection with that paper. It is understood that Mr. Carl Hering will do part of the editorial work in connection with his engagements as an expert in Philadelphia. Dr. Bell will devote himself to the important field of power transmission and railway development. His recent book, written in conjunction with Mr. O. T. Crosby, on "The Electric Railway," is a most valuable and useful publication.

College Notes.

PENNSYLVANIA STATE COLLEGE.

THROUGH the liberality of the Westinghouse Electric Co., a 500 light alternating incandescent dynamo, with constant current exciter, compensator, alternating voltmeter and ammeter, and a number of converters, have recently been added to the equipment of the electrical engineering department.

The trustees, on recommendation of Prof. Osmond, about a year ago, authorized the extension of the course to include a fifth year. Accordingly, the course for the degree of E. E. now requires five years; but at the end of the junior year, students who cannot remain two more years may take an approved course of one year (taken from the two) and receive the degree of B. S. in electrotechnics. This extension to five years makes it possible to bring into the course a large amount of mechanical engineering and also increase somewhat the distinctive electrical work both in the applications and in the advanced theory of electricity.

Students of the electrical department, especially Messrs. Bohn and Loyd, have recently designed and constructed a dynamo, on castings sent by Mr. Greenwood, of the Rockhill Furnace, for lighting the machine and car shops and other buildings of the furnace.

MOTORS ON THE U. S. S. "MIANTONOMOH."

INFORMATION comes to us that the Crocker-Wheeler Electric Company has just placed four of its perfected fan outfits in the turrets of the new U. S. S. "Miantonomoh," to blow the smoke away from the guns. This is surely a novel use of the electric fan.

Literature.

Magnetic Induction in Iron and other Metals. By J. A. Ewing, M. A., F. R. S. S., L. & E., M. I. C. E., D. Sc. London, *The Electrician Printing and Publishing Co.* 351 pp., 5 x 8 inches. price, $4.

For some time past the London *Electrician* has been publishing a series of excellent articles from the pen of Prof. J. A. Ewing, whose work in magnetism is generally recognized as classical. In these articles Prof. Ewing, without entering too deeply into the history of the subject, has placed before his readers an accurate record of the more recent and important work done in magnetism; and these articles, reprinted in book form, are now before us.

The work begins very properly with an explanation of the fundamental ideas embodied in magnetic work and measurement, a description of the methods of measurement usually employed for determining the value of iron and steel, and a number of valuable data exhibiting the results of measurements on various specimens of iron, steel, nickel and cobalt. The subject of magnetic hysteresis, a term which, by the way, was coined by Prof. Ewing, is naturally treated of with considerable fullness, and induction by very weak and very strong magnetic forces is described, together with the influence of temperature and stress.

Prof. Ewing then takes up the magnetic circuit with particular reference to the application of the theory to the construction of machines. The last chapter of the work is devoted to the molecular theories of magnetism, beginning with that of Poisson and Weber, Ampere and others, to which he has added his own most interesting theory recently developed.

The author, to use his own language, has, throughout, endeavored to familiarize the student with the notion of intensity of magnetization, (I) as well as with the notion of magnetic induction (**B**). "It has been urged by some writers," says Prof. Ewing, "that the alternative which is in this way offered is unnecessary and confusing, and that if we keep "**B**" we may dispense with "**I**." The scientific value and the practical utility of "**B**" are so obvious that no one proposes to avoid using that. It is "**I**" that we are told must go. In this cry the author is by no means disposed to join. It is not too much to say that in stating the magnetic qualities of a metal the quantity "**I**" is of primary importance. The facts of saturation, the molecular theory, and the phenomena of magneto-optics, all demonstrate its physical reality and its fundamental interest."

Like all of Prof. Ewing's works, this one is also enriched by copious reference to original publications and papers, so that the book as a whole presents the best résumé of this subject extant.

Practical Electrical Engineering. London, *Biggs & Co.* New York, *J. A. Penman.* Published in parts. Price, 75 cents per part.

This work which has been undertaken by some of the best electrical writers in England has already received a notice at our hands, and we have now before us Volume I, complete. This contains exhaustive chapters on electric measurements, steam engineering as applied to electric distribution, the construction of central stations, switchboards, etc., and the principal systems of underground electrical conduits employed in England, and to some extent in this country. There is also before us Part 12, consisting of the first chapters on secondary batteries, which contain excellent descriptions of the most modern types of cells, together with very clear illustrations.

Armature and Field Magnet Winding. By Edward Trevert, Lynn, Mass. *Bubier Publishing Co.:* 1892. 113 pp., 5 x 6½ inches. Illustrated. Price, 50 cents.

Although many works treat of the methods of design and the calculation of the windings for armatures and field magnets of dynamo-electric machinery, little has appeared on the practical methods of winding as carried out in the workshop. The author has in the present volume devoted particular attention to the latter subject, a variety of methods of winding drum and ring armatures being described from the workman's standpoint. In the short treatise on the method of calculating windings, the author has followed Kapp's method to good advantage.

Annuaire pour l'an 1892. Bureau des Longitudes, Paris. *Gauthiers-Villars & Fils.* Price, 1 franc 50 cent.

Besides the practical information contained in the *Annuaire* each year, the volume for 1892 includes a number of articles from the pens of well-known savants on monetary matters, statistics, geography, mineralogy, etc.

The Elements of Electric Lighting. By Philip Atkinson, A. M., Ph. D. Seventh edition, fully revised and enlarged. New York, *D. Van Nostrand & Co.* 260 pp. Price, $1.50.

This little work is so well known as to require no detailed review at this time, and it will therefore suffice it to say that it is brought down to date. It will give the layman and student an excellent idea of the modern methods and apparatus for generating, measuring, storing and distributing electricity.

The Ventilation of Buildings. By Alfred R. Woolff, M. E. Second edition. Pamphlet, 32 pp., 6 x 9 inches. Price, 25 cents.

Letters to the Editor.

LONG-DISTANCE TRANSMISSION AT ONE MILLION VOLTS.

In a communication to The Electrical Engineer of January 20th I sketched a system for the distribution of power by means of high-pressure continuous currents. I will now refer in more detail to the generating machinery, and to the line likely to prove most successful.

For some years it has been the practice in many central stations to operate arc generators in series, supplying lamps and motors; a further evidence has come to hand in the last few weeks of a system of this character at Genoa, which is on a considerable scale. I may therefore say at once that I have contemplated the operation simply of a large number of the ordinary constant-current generators complete with regulators running at any speed independently of one another in series. Nothing more nor less than this. Similarly for the motors, the constant-current machines with regulator operating on field for constant speed or constant voltage or ampereage of a driven machine.

Thury employs for his generators one field circuit which may or may not be a saving.

After experimenting with a static induction machine I have come to the conclusion, that up to 50,000 to 100,000 volts, overhead bare wires may be used, and consideration will show that at this pressure, the total energy of Niagara might be economically transmitted into the greater industrial centres of the North American continent.

As regards the line, above 100,000 volts, it may be liable to brush discharges, especially over a damp insulator. For high pressures therefore I would use oil insulated cables in which the brush or silent discharge is entirely suppressed and with which I believe pressures up to 2,000,000 or 3,000,000 volts can be readily carried.

It is a point for consideration as to whether petroleum or a viscous fluid is preferable. As in oil a movement of the fluid or apparent ebullition precedes discharge, it is probable that a difficultly movable fluid, as some qualities of Isolatine, would raise the pressure of discharge.

In the Brooks underground conduit, solid paraffine with oil in addition has been proposed. Of this, and any other oil insulated cables I should be glad to have particulars.

George Edensor Dorman.

Chicago, Ill., March 1st, 1892.

MOISTURE-PROOF CONSTRUCTION FOR IRON ROOFS.

With regard to Mr. J. Edwin Giles' communication on the iron roofs of the Edison Station at Hazelton, Pa., contained in your issue of Feb. 10, 1892, we feel certain that Mr. Giles could not have read our communication in regard to the subject of iron roofs published in your issue of Jan. 20, 1892, because there we described several methods in use by us, and two methods which give a thoroughly fireproof construction and not as expensive as the method he describes. We regret exceedingly that Mr. Giles did not call on us prior to the building of his station, as we feel sure we could have built him one which would have been more satisfactory than the one he now has. It seems foolish to have to put in an entire interior lining as he has done, which he himself says acts as a gutter to conduct the water which forms on the underside of the corrugated iron roof and running down to the sides of the building. We feel sure that with the fireproof sheathing we described in your issue of Jan. 20th no moisture will condense on the underside of the corrugated iron roof covering.

In regard to the covering describod by Dr. Amory, manager of the Brookline Gas Light Co., we would say we understand that this station has not been in use as yet, so we are not able to learn whether his experiment will be a successful one or not. Mr. Giles evidently failed to communicate with parties who had had experience in regard to the matter of iron roofs. Our company has made a special study of this for a great number of years, and we feel sure that we can give anybody satisfactory information should they favor us with communications on the subject.

Burr K. Field,
Berlin Iron Bridge Company. Vice-President.
East Berlin, Conn., Feb. 19, 1892.

CONDENSATION ON IRON ROOFS.

We have noticed an article in your issue of Feb. 10th by Mr. J. Edwin Giles, in regard to the condensation of moisture on the underside of iron roofs. We desire to state for his benefit, and that of others who have had trouble of a similar kind, that this problem can be solved in a satisfactory manner by the use of Mackite plaster boards as a lining for the corrugated iron, as we have practically demonstrated repeatedly in electric stations, machine shops, freight depots, etc. The construction with the plaster boards is very simple, as the fastenings holding the sheets of corrugated iron pass directly through the boards, securing them in place also.

We shipped several thousand square feet of Mackite to the Edison Electric Illuminating Co., of Easton, Pa., last September, to be used under the roof of their station, and we can refer to them. The advantage must be seen at a glance, this material affording a dry and fireproof lining for an iron roof, at a comparatively very low cost. We shall be pleased to correspond with any of your readers who are contemplating the erection of a roof of this description.

Eastern Plaster Board Company.

New York City.

WORLD'S ELECTRICAL CONGRESS.

It has been arranged by Mr. C. C. Bonney, President of the World's Congress Auxiliary, Mr. O. Chanute, Chairman of the Engineering Congress Committee, and Mr. Elisha Gray, Chairman of the Electrical Congress Committee, that the section of the Engineering Congress relating to Electrical Engineering shall be merged into the World's Electrical Congress.

Due notice of this agreement from the office of the World's Congress Auxiliary will follow the recently distributed circular relating to the Engineering Congress.

H. S. Carhart,
Secretary of the World's Electrical Congress Committee.

POSITION OF FEED-WATER HEATERS.

I have noticed by an inspection of various electric light and power plants throughout this country—that where condensing engines are used—in some cases a closed feed-water heater is placed *between* engine and condenser, and in other cases live steam is used to heat the feed-water or else the feed-water is not heated at all.

This seems an important point, and I should be glad to hear the expressions of opinions of various engineers of experience on the subject.

R. B. Owens.

University of Nebraska,
Lincoln, Neb., Feb. 20, 1892.

BUFFALO CONVENTION TRAIN SERVICE.

On behalf of the National Electric Light Association I desire to tender thanks through the electrical press to the following named gentlemen, for the very efficient service rendered and the numerous courtesis extended to our delegates during the recent Convention in Buffalo:

Mr. M. C. Roach, Gen. Eastern Pass. Agt., N. Y. C. & H. R. R. R., New York City; Mr. Edson J. Weeks, Gen. Agt. Pass. Dept., Buffalo, N. Y.; Mr. H. H. Parry, City Ticket Agt., Buffalo, N. Y.; Mr. J. C. Yager, Div. Supt. Wagner Palace Car Co., New York.

C. O. Baker, Jr.,
Master of Transportation.

National Electric Light Association,
New York March 1st, 1892.

Society and Club Notes.

GEORGE CUTTER ON INSULATION.

At the last meeting of the Brotherhood of Electrical Mechanics of Chicago, a large and attentive audience listened to a talk on "Conductivity and Insulation." Mr. Cutter's recent illness had prevented him from preparing a proposed series of experiments on this subject, but his lecture drew out quite a little discussion as to modern wires and insulations. After calling attention to the relation between the terms "conductivity" and "insulation," he showed how the conductivity of the wires in common use was brought to a high state long before the more thorough means of insulation were adopted. He then dwelt on the comparative value of various insulating materials, and called on the electrical mechanics to sustain the results produced by high-class material by taking good care of the joints and other trying spots.

A brief discussion on making joints and on means of testing insulation followed this off-hand talk, which incidentally paid a high tribute to the work and opportunities of the electrical mechanic.

THE PHILADELPHIA CENTURY CLUB.

At a recent meeting of the Century Electric Club, held Monday, February 8th, the following amendment was made to the by-laws:

"The membership of this organization shall consist of two classes, active and honorary. Active members shall be over eighteen years of age, and shall have been at least one year in practical electrical work. They shall also have a certain amount of theoretical knowledge, and their eligibility shall be thoroughly investigated by the membership committee."

Anybody desiring to become a member shall apply to Mr. Charles W. Carnes, Penn Mutual Building, Philadelphia, chairman of the membership committee.

FRANKLIN INSTITUTE.

At the meeting of the Electrical Section of the Franklin Institute, held January 5, Mr. H. S. Hering gave a description of some types of recording volt and ammeters, and suggested some new modifications. Mr. W. S. Aldrich continued his remarks upon electromagnetic machinery, with lantern illustrations. Prof. Houston read a paper on "An Early Conception of Magnetic Field," which was referred for publication.

At the meeting of the American Institute of Electrical Engineers, at 12 West 31st street, on March 15, Mr. A. Wurts will read an interesting paper on "Lightning Arresters."

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEBRUARY 23, 1892.

Alarms and Signals:—

Electrical Burglar-Alarm for Windows, F. C. Page, 469,266. Filed June 16, 1891.

Fire-Alarm System, H. Redding, 469,376. Filed May 15, 1891.

Has for its object to enable the circuit to be closed and the gongs briefly operated for the purpose of testing the system without giving the full alarm.

Electrical High and Low Water Alarm, A. C. McConnell, 469,424. Filed Dec. 2, 1890.

Conductors, Conduits and Insulators:—

Molding for Electric Wires, W. Gritten and A. Parmly, 469,241. Filed Apr. 27, 1891.

A molding for wires made of slag-wool.

Electric Conductor for Metallic Circuits, S. W. Holman, 469,248. Filed Oct. 10, 1891.

A metallic circuit conductor in which both wires of each circuit are arranged helically leaving an air-space in the centre of the cable.

Conduit for Cable or Electric Tramways, G. S. Morison, 469,262. Filed Dec. 29, 1890.

Claim 1 follows:

A railway conduit constructed in sections, the side pieces of each section overlapping each other at opposite ends of the section whereby when the sections are placed together, end to end, openings will be left alternately on opposite sides as pockets.

Tube for Electric Conductors, E. T. Greenfield, 469,469. Filed Mar. 21, 1891.

A conduit consisting of a small tube thrust into a larger tube which has been partly filled with a soft insulating material, which material is then allowed to harden or set.

Electric Cable, H. V. Hayes and J. S. Stone, 469,475. Filed Oct. 12, 1891.

A cable consisting of a number of associated pairs of compound conductors laid up in reversed layers and properly insulated.

Conduit for Electric Conductors, E. T. Greenfield, 469,470. Filed Aug. 14, 1891.

A junction sleeve or collar having a non-conducting ring imbedded in its inner surface.

Electric Cable, H. V. Hayes, 469,522. Filed Aug. 16, 1889.

A metallic circuit in which the direct and return wires are combined spirally with insulating material so that the thickness of the latter from the common axis of the spirals to the inner surfaces of the wires is greater than its thickness on the exterior surfaces.

Dynamos and Motors:—

Speed-Regulator for Dynamos or Motors, L. H. Leber, 469,257. Filed May 11, 1891.

A ball governor which operates by breaking the circuit completely when the machine attains too high a speed.

Electric Machine, M. von Dolivo-Dobrowolsky, 469,515. Filed Aug. 3, 1891.

A system in which the current-generating and the current-receiving devices, which are equal in number, are severally connected to form closed circuits, while the conducting or line wires are connected to equidistant points of the said circuits, or to the united terminals of the respective devices.

Dynamo-Electric Machine, J. Sohlman, 469,281. Filed Sept. 18, 1891.

Has two stationary annular armatures with induction coils, a central shaft carrying two groups of field-magnets and revolving within the two armatures; the pairs of armatures in groups having an equal number of poles, and the position of the corresponding elements of the pairs being relatively adjustable.

Electromagnetic Reciprocating Engine, M. J. Wightman, 469,441. Filed Feb. 5, 1891.

A reciprocating motor in which it is possible to alter the length of the stroke, the number of strokes per minute, and the relative strength of the force of the going and returning motion.

Galvanic and Thermo-Electric Batteries:—

Diaphragm for Electrical Cells, C. N. Waite, 469,428. Filed Feb. 18, 1891.

A dense, compact film of a metallic albuminate.

Lamps and Appurtenances:—

Electric Arc Lamp, W. D. Graves, 469,347. Filed Nov 9, 1891.

An automatic regulating device for arc lamps.

Electric Arc Lamp, F. R. Boardman, 469,362. Filed Jan. 27, 1891.

Consists of an insulated box containing a refractory block with two carbon holders rigidly connected to the box on opposite sides by insulated connections, a spring or weight within each holder feeding the carbons toward the block, a bayonet joint secured to one end of the carbon-holder, and a corresponding attachment upon the base of the lamp.

Incandescent Lamp, F. H. Manchester, 469,482. Filed Nov. 4, 1891.

An incandescent lamp base which shall be unaffected by change of temperature.

Incandescent Lamp, F. H. Manchester, 469,483. Filed Nov. 4, 1891.

Has for its object a lamp base which shall be more durable and less expensive than those in ordinary use.

Electric Lighting System, J. F. McElroy, 469,656. Filed June 4, 1891.

A car-lighting system in which the generator is operated by the motion of the train.

Miscellaneous :—

Electric Hose-Coupling, J. B. Strauss, 469,283. Filed Sept. 14, 1891.

An electric hose-coupling by means of which signals may be communicated through wires laid within the casing of the hose through any number of lengths, by means of which the firemen may communicate with the engineer.

Poison Cabinet, E. G. Kubler, 469,349. Filed Dec. 14, 1891.

Has for its object to prevent more than one bottle being removed from the cabinet at once, thus avoiding accidents due to misplacement of the bottles.

Automatic Electric Gas-Lighting Burner, R. C. Nourse and T. W. Lane, 469,408. Filed Dec. 29, 1890.

Electromagnetic Stop-Motion for Steam Engines, W. W. Hailstone, 469,471. Filed June 2, 1891.

An arrangement by which the admission of steam to a cylinder may be stopped by means of an electric current under the control of circuit closers located at a distance.

Electric Elevator. R. Watson, 469,361. Filed Oct. 8, 1891.

An automatic governor controlled by the load upon the elevator, increasing the speed of the latter as the load is decreased and vice versa.

Electrical Atomizer, C. Lightbody, 469,481. Filed Apr. 10, 1891.

Apparatus for Pointing Carbon Pencils, P. Moses, 469,486. Filed Apr. 21, 1890.

Process of and Apparatus for Electroplating the Hulls of Vessels, A. D. Buchanan, 469,538. Filed Feb. 20, 1891.

Process consists in docking the vessel, incasing its hull in a flexible envelope, filling the envelope with a metallic solution, and making electric connection between the solution and the hull of the vessel.

Automatic Advertising Apparatus, W. C. Jennings, 469,652. Filed May 20, 1891.

Apparatus for Stopping Engines, J. P. Tirrell, 469,669. Filed Oct. 24, 1891.

A power-controlling device actuated by an electrically-controlled coupling mechanism.

Railways and Appliances :—

Electric Railway, W. S. Smith, 469,280. Filed Sept. 3, 1891.

Claim 1 follows:

The combination, with a trolley arm, of a frame supporting same, gearing for swinging the trolley arm about a vertical pivot, and a shaft for operating said gearing provided with a handle for the motorman.

Commutator Cleaning Device, W. J Phelps, 469,316. Filed Feb. 7, 1891.

Provides means whereby a street car operator can conveniently clean the commutator without leaving his position at the end of the car.

Overhead Conductor for Electric Railways, E. M. Bentley, 469,353. Filed Sept. 17, 1881.

Railway Signaling Apparatus, F. I. Myers, 469,438. Filed July 9, 1891.

Has for its object to clear a signal immediately on the last wheel of the train leaving the block, irrespective of the length of the train.

Brake for Electric Cars, E. S. Amrock, 469,383. Filed Aug. 10, 1891.

Claim 1 follows:

In the combination with a car provided with and operated by an electric motor, a hydrostatic brake, and a connection between the brake and the motor for automatically breaking the circuit of the motor when the brake is applied.

Switches and Cut-Outs :—

Automatic Disconnector, A. L. Johnston, 469,258. Filed Sept. 10, 1891.

A disconnector for railway lighting circuits.

Telegraphs : -

Electric-Telegraph Apparatus, J. Robinson, 469,273. Filed Jan. 21, 1891.

An apparatus by which the movements of a transmitting handle indicating communications from the transmitter, may visibly be reproduced by the duplicate movement of a pointer corresponding to that of the transmitting handle.

Telephones and Apparatus:—

Telephone Support, H. V. Hayes, 469,474. Filed June 22, 1891.

Signal Device for Telephone Pay Stations, W. Gray, 469,649. Filed Apr. 16, 1890.

A coin channel and guide and a signal sounding device having a part located in the path of movement of the falling coin.

Signal Device for Telephone Pay Stations, W. Gray, 469,650. Filed Dec. 15, 1890.

Similar in its object to No. 469,649.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 2, 1892.

Alarms and Signals :—

Non-Interfering Fire-Alarm Telegraph Box, F. F. Loomis, 469,745. Filed Aug. 31, 1891.

Electric Alarm Clock, J. Yungbauer, 469,802. Filed June 22, 1891.

Conductors, Conduits and Insulators :—

Underground Electric Conduit, E. P. Robbins, 469,723. Filed Feb. 24, 1890.

An underground electric conduit simple and inexpensive of construction, generally applicable to all kinds of roadways, convenient of access and as nearly as possible water-tight.

Distributing Box for Cable Systems, C. H. Wilson, 469,765. Filed Sept. 19, 1889.

Conduit System for Electric Railways, J. E. Waller and E. Manville, 469,828. Filed May 13, 1890.

Claim 7 follows:

In combination with a flexible conductor in a conduit, a collecting arm and shank detachably secured to one another by suitable attachments, said attachments engaging through slots in one of said parts and adapted to be disengaged at will.

Insulator, C. N. Hammond, 469,940. Filed Sept. 30, 1891.

An insulator having a straight recess to hold the wire and a curved slot leading into the recess for the introduction of the wire.

Distribution:—

System of Electrical Distribution, W. Stanley, Jr., 469,809. Filed Aug. 15, 1888.

Employs a dynamo generating alternating current and a number of converters to transform the current from one potential to another in a secondary circuit in which the lamps or other translating devices are included.

Dynamos and Motors:—

Device for Controlling Electric Motors, A. L. Parcelle, 469,712. Filed Mar. 14, 1891.

An arrangement by which the circuit may be closed quickly through the field coils and gradually admitted to the armature coils as the proper counter-electromotive force is being developed.

Dynamo-Electric Machines, E. A. Sperry, 469,725. Filed Jan. 10, 1890.

A rotating shaft with an annular armature, rods passing through the same, a supporting spider for such rods, said rods flattened at the point or points where the armature coils pass them, and a field magnet.

Electromagnetic Machine, R. Lundell, 469,862. Filed Aug. 5, 1891.

Claim 1 follows:

The combination of a disc armature and a double field magnet having a set of positive and negative poles on each side of the disc armature, each set of pole-pieces being magnetized by a single magnetizing coil.

Apparatus for Illuminating Cars of Cable Roads, C. E. Scribner and E. P. Warner, 469,873. Filed Oct. 13, 1891.

A dynamo placed upon a cable car and operated by gearing to the axles of the car.

Commutator Brush and Holder, C. D. Jenney, 469,806. Filed Jan. 16, 1891.

Armature Winding for Dynamo-Electric Machines, R. Eickemeyer, 469,917. Filed June 1, 1891.

A low tension winding composed of bendable metal in one or more separate lengths or strands and shaped in the form of a loop having a straight long side, a straight short side, and correspondingly curved ends, which are offset centrally in opposite directions.

Dynamo or Motor, R. C. Kintzing, 470,057. Filed Oct. 13, 1891.

Consists of a hollow spherical shell containing the field magnet cores, removably attached to the shell, and a spherical armature core.

Motor, La M. C. Atwood, 470,095. Filed Sept. 1, 1890.

A motor for street cars employing hydraulic gears.

Galvanic and Thermo-Electric Batteries :—

Electric Battery, E. Ortelli, 470,073. Filed Sept. 18, 1890.

Based upon the property which bromine, chlorine, fluorine and iodine have of uniting with hydrogen and forming strong acids soluble in water, which attack almost all metals and produce hydrogen.

Voltaic Battery, H. I. Harris. 470,123. Filed Apr. 4. 1891.

An improved construction of primary battery by means of which a non-fuming solution in the carbon cells may be used.

Heating :—

Electrically Heated Smoothing Iron, W. Mitchell, 469,792. Filed May 27, 1891.

Electric Soldering Tool, J. J. Ritter, 469,949. Filed Aug. 27, 1891.

Lamps and Appurtenances :—

Extension Electrolier, C. Deavs, 469,895. Filed Nov. 23, 1891.

Electric Light Attachment for Lamps, R C. Putnam, 470,008. Filed Sept. 5, 1891.

Measurement :—

Electric Meter, J. J. Wood, 469,800. Filed Oct. 27, 1891.

An electric motor driven by the current to be measured and a magnetic retarder consisting of a conducting cylinder revolving in inductive proximity to magnetic poles approaching it exteriorally.

Metal-Working :—

Electric Link-Welding Machine, C. L. Coffin, 470,038. Filed Apr. 25, 1891.

Miscellaneous :—

Electromagnet, A. D. Ayres, 469,672. Filed May 23, 1891.

A series of paramagnetically-encased coils bound together and a series of paramagnetic armatures magnetically separated and bound together, and a commutator whereby the successive energizing of the coils produces a prolonged movement of the magnets and armatures.

Galvanic Electric Plaster, J. W. Shults, 469,796. Filed May 16, 1891.

Galvanic Electric Plaster, J. W. Shults, 469,797. Filed June 29, 1891.

Electrical Releasing-Device for Target-Traps, P. North, 469,905. Filed May 6, 1891.

Method of, and Apparatus for, Rating Watch-Balances, C. E. Emery, 469,967. Filed Apr. 10, 1891.

Lightning Arrester, C. F. Scott and A. Wurts, 470,018. Filed July 17, 1891.

A discharge plate connected with one side of a circuit and a second discharge plate connected with the earth, and apparatus to bring said plates into proximity at rapidly-recurring intervals.

Adjustable Suspension Apparatus for Electrical Translating Devices, H. D. Sisson, 470,080. Filed Sept. 24, 1891.

Automatic Valve-Controller, W. H. Kilbourn, 470,143. Filed Dec. 18, 1890.

Electrical Device for Stopping Horses, A. B. Holson, 470,155. Filed Feb. 14, 1891.

Electric Elevator, C. J. Sturgeon, 470,158. Filed Jan. 27, 1891.

Circuit-Interrupting Device, A. Wurts, 470,161. Filed Apr. 23, 1891.

A complete shunt circuit of high resistance around the contact points of the main circuit interrupter, causing its connection to be severed subsequently.

Railways and Appliances :—

Automatic Trolley Catch, S. A. Shepard and F. P. Lang, 469,750. Filed Aug. 7, 1891.

A trolley catch having a ratchet and pawl, a wedge adapted to engage the pawl, a strap which bears on the wedge and means for winding a spring connected with the ratchet.

Electric Locomotive, T. L. Willson, 469,799. Filed July 3, 1891.

An electric motor having great traction power adapted to very heavy work, steep grade, etc.

Contact Device for Electric Railways, J. C. Love, 469,861. Filed June 16, 1891.

An arrangement for maintaining a constant pressure of the trolley wheel upon the wire.

Railway Station, J. G. Emery, Jr., 469,882. Filed March 30, 1891.

Claim 1 follows:

In devices for operating a movable railway station, arranged to travel on a side track alongside of a moving train on a main track, an electricity-generating device on the train on the main track adapted to supply electric motive power to the auxiliary train on the side track.

Trolley for Electric Railways, W. H. Morgan, 469,899. Filed June 24, 1891.

Has for its object to provide means whereby the wearing parts of the trolley can readily be replaced when worn.

Electric Railway Signal, W. Holloway, 470,129. Filed Aug. 21, 1891.

Switches and Cut-Outs :—

Fuse for Electric Circuits, C. F. Scott and A. Wurts, 470,014. Filed Oct. 16, 1891.

A fuse having great carrying capacity, low melting point, small mass and which will not deteriorate.

Telegraphs :—

Telegraph Apparatus for Branch Offices, J. B. Hurd, 469,856. Filed March 7, 1890.

Adapted to connect local stations with the main line at a central office so that a local operator may have the means of communication with the central office to inform the latter of line trouble which he may detect.

Telephones and Apparatus :—

Telephony, W. C. Lockwood, 469,706. Filed Sept. 29, 1891.

A combination of the horseshoe magnets with opposing poles, the coils in one being in a local circuit embracing a battery and transmitter and the coils in both being in circuit with the main line and ground.

Telephone Transmitter, J. C. Goulding, 469,782. Filed June 12, 1891.

A transmitter that may be placed at any desired height for the convenience of the user.

Electromagnetic Annunciator, F. W. Dunbar, 469,995. Filed Nov. 23, 1891.

A visual annunciator for telephone systems.

Telephone System, T. W. O'Brien, 469,865. Filed Nov. 12, 1890.

Has for its object to enable all signals to be transmitted by means of a single signal transmitter common to the whole system.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT

In advertising, don't try to make an incandescent lamp do the work of an arc.

THE "P. & M." AUTOMATIC ELECTRIC DROP LIGHT.

A LINE of very interesting and useful novelties just put upon the market by the Southern Electric Company, of Baltimore, Md., are destined to improve the present methods of electric light installations and add to their convenience and beauty. The improvements are quite marked over the present methods and fixtures, and a brief description will be found of interest. The "P. & M." automatic electric drop light illustrated herewith in Figs. 1 and 2 is designed to supersede complicated and expensive fixtures, whose delicately balanced system of pulley and weights has made their use of limited extent. The drop light, broadly speaking, consists of a drum and its attached lamp cord, running in grooves to insure precision; the whole fixture with its ornamental brass trimmings, is a credit to its makers, while its small size and neat appearance add greatly to its attractiveness.

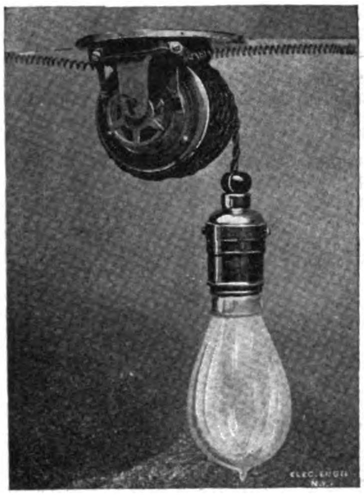

FIG. 1.—THE "P. & M." AUTOMATIC ELECTRIC DROP LIGHT.

The mechanism is that of the ordinary spring roller used so extensively on window curtains; the certainty of its action having been so thoroughly demonstrated any comment is unnecessary beyond noting the superior finish and adjustment of the different parts.

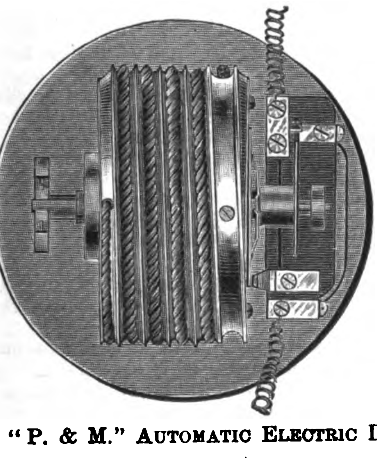

FIG. 2.—THE "P. & M." AUTOMATIC ELECTRIC DROP LIGHT.

Only one size of cord and drum is made at present; any change in the size of lamp or style of shade may be made at pleasure; the inconvenience of adding or subtracting weights so as to balance the parts having been entirely done away with.

If, in its normal position, the lamp is supposed to hang with the current turned off and it be desired to light it, any downward motion of the lamp releases the switch carried by the roller and turns on the current. If, on the other hand, it is desired to put out the light, the slightest upward impulse is sufficient. The mechanism is thus direct and positive and not liable to get out of order, the current is under perfect control by the slightest motion of the hand, and the lamp capable of any desired adjustment as to its position.

A double-pole cut-out is located under the roller block and is a complete protection against any abnormal increase of current. The perfection of the device leaves little to be desired, and we recommend it to the consideration of the trade.

The cuts shown are one-half size. Mr. G. E. Painter, the electrician of the company, is the inventor.

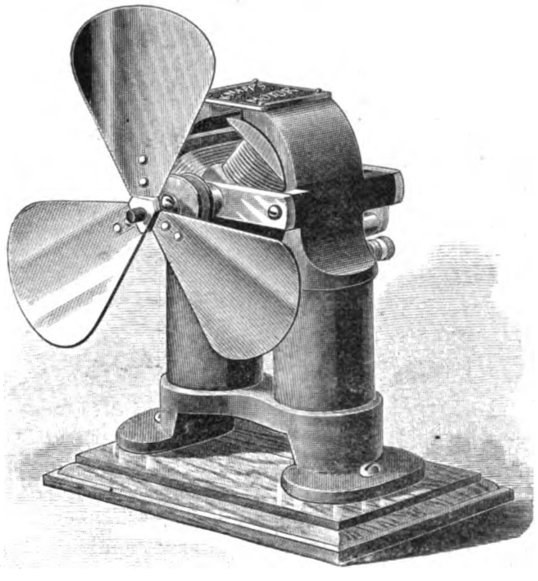
THE "STORELECTRO" CAR.

ON Saturday, February 29, the first public trial trip was made of the new storage battery car built by the Ford-Washburn Storelectro Co., of Cleveland, Ohio, and proved eminently successful. The car is 26 feet in length over all, and carries 180 cells of battery placed under the seats, operating a 40 h. p. Ford-Washburn motor. With this equipment a loaded trailer was drawn up a 1½ per cent. grade at the rate of 15 miles per hour. On an ordinary track one charge it is claimed will last for 50 miles.

Superintendent George Mulhern, of the Woodland Avenue and West Side Street Railroad Company, who was on the car at the time of the test, was very favorably impressed with the result. The system, he says, will probably be adopted by his company, and, meantime, the experimental car, the "Ideal," will make regular trips on the road.

THE KNAPP FAN MOTOR.

WE illustrate herewith the Knapp motor for light work, just put upon the market by the Knapp Electric and Novelty Co., of 34 Warren street, N. Y. It stands 6 inches high, and with a 6-inch fan weighs less than four lbs. The binding posts to circuit are not, as usual, on the wooden base but are on the iron of the magnetic circuit, and well insulated. In this manner, it is made easy to remove the motor from its ordinary base and to fasten it to the edge of a desk or table, when, of course, a fan of much larger diameter can be used. The motor is sent out, however, mounted on a neat mahogany stand, to which it is secured by a neat iron pedestal. The motor is carefully finished in enamel, and has full brass trimmings, being a good piece of work all through. The present size, with fan, is being marketed at $5. It will run with any of the ordinary motor batteries, and appears to be quite economical of current.



THE KNAPP FAN MOTOR.

SEBASTIAN LATHE CO.

THE new catalogue of the Sebastian Lathe Co., of 41, 43 and 45 Central avenue, Cincinnati, O., contains a very complete list of lathes for both metal and wood working, planers, drills, shaping machines, power saws, shafting, hangers, and mechanics supplies of every conceivable nature. In addition to this, the catalogue contains a list of useful books for mechanics and amateurs.

CHEAPER ALCOHOL FOR MANUFACTURING PURPOSES.

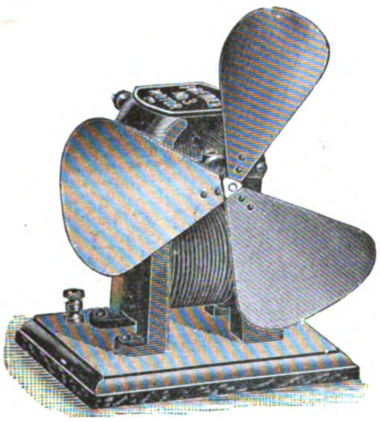
THE recent discovery of a new process alcohol for use in the arts by Prof. Wm. Read, of Needham, Mass., is worthy of notice. For many years the consumers of alcohol for manufacturing purposes have labored under the disadvantages of a heavy revenue tax and the high rates set by the whiskey trust, having only as a substitute the foully smelling wood alcohol or the fouler fusil oil, which was a poor one at the best. Several years ago Prof. Read in his chemical researches discovered a formula and process which, carefully perfected, has, it is confidently asserted, opened a field as wide as that which lay before the discoverers of the oil territory.

The spirit manufactured under his process is pure and colorless and in its properties is exactly identical with the spirit in present use except that its "cutting" or solvent properties are far more active than those of the spirits at present on the market. One of its greatest values appears to lie in the immense saving it will make by redissolving spirit varnishes which have become thick, dry or positively hard from exposure to the air by careless workmen, large quantities of which varnishes are used by electric manufacturing companies for insulating purposes.

Its burning properties are identical with those of pure grain alcohol. The Massachusetts Chemical Co. has been organized to handle this new chemical, and they are now erecting laboratories sufficient to supply the enormous demand which has already arisen for their product.

THE PREMIER ELECTRIC MOTOR.

WE illustrate on this page the No. 2 Premier electric motor, built by the Premier Electric Co. of 11 Whipple street, Brooklyn, who are building up a large business in these motors and in batteries to run them. This little motor is made of the best soft iron, enameled, carefully insulated and wound with the best double-covered wire. It has small oil cups on its bearings, a brass driving pulley, binding posts, etc., and easily adjustable brushes. It carries a 5-inch fan. The No. 3, size takes a inch fan; and the concern are now building a dainty little No. 1, which will have a small but effective fan, to sell at $3. It is interesting to note the rapid stages by which improvements in small motor manufacturing have reduced the price to the point where it seems impossible that anybody who wants relief from the heat will refuse to buy.



PREMIER ELECTRIC MOTOR.

The Premier Co. are now building a two-story factory at 17 and 19 Whipple street, which they expect to occupy before April 1, and where they will manufacture not only their motors but the Premier Grenet and Premier carbon batteries They expect also to put on the market shortly an improved dry battery, learners' telegraph instruments and a number of popular electrical novelties. The company to-day is a copartnership composed of Mr. A. Rodrigues, Mr. M. R. Rodrigues, a well-known electrician, and Mr. E. F. Kelly, manager of the sales department.

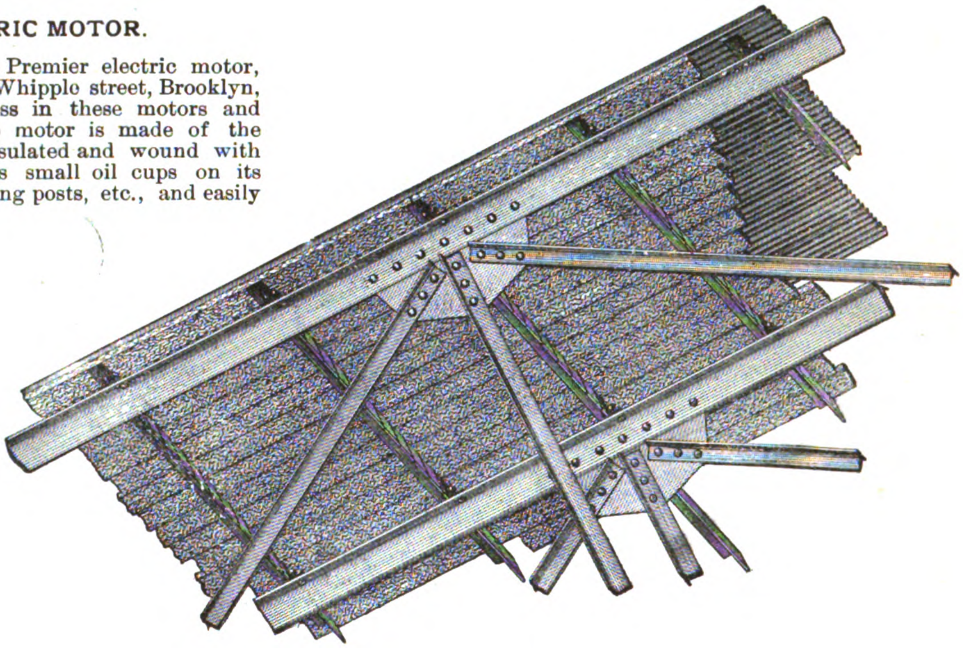
THE JOHNSON STANDARDIZING CO.

THE JOHNSON STANDARDIZING COMPANY is a new corporation organized to own and control, for the purpose of greater convenience, the manifold inventions, contracts, experimental work and general electrical properties heretofore owned or controlled individually by Mr. Edward H. Johnson. Mr. Johnson's personal operations in the way developing and marketing not only his own inventions but those of numerous young inventors who have turned to him for help and advice have become so extensive that it was found advisable in many ways to assign them all to a small close corporation, the stock of which is, of course, owned almost wholly by Mr. Johnson himself.

MACKITE PLASTER BOARDS IN ELECTRIC LIGHT STATIONS.

WITH the experience gained during the last ten years, central station construction has made great progress, and in no detail is this more marked than in the precautions taken to make stations of as fireproof a character as possible. While some of the materials of which such a building is composed may be combustible, much can be done towards reducing the fire risk by the application of protective materials, which are designed to prevent the fire from getting at the timbers and beams.

One of the most interesting and valuable materials of this kind is that known as the Mackite plaster board, which has already gone into extensive use in this country after having been in use abroad for a long time. These Mackite plaster boards, which are made by the Eastern Plaster Board Co., of 52 Broad street, this city, are generally four feet long. Reeds of the same length are placed in the molds in which the boards are made, a mixture of water, plaster-of-paris, fibre, ground cork, etc., which is used, being poured over them, and worked around them, so that when the board is dry the reeds shall be nowhere exposed. The reeds give the boards longitudinal strength, enabling them to be used and handled in these lengths; the fibre makes the boards tough, elastic and strong transversely; the cork waste increases their sound-deadening qualities, while the plaster-of-paris makes them a solid fireproof board, furnishing the rough base for the hard finish coat which is applied to them after they are nailed in position.



"MACKITE" PLASTER BOARD ROOFING.

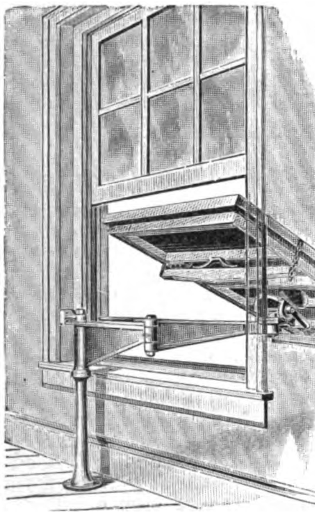
The boards are easily and rapidly nailed in place, tinned wire nails with large heads being used. As soon as the joints between them are filled with plaster, the skin or hard finish coat may be applied, and, as this dries quickly, the building is immediately ready for occupancy. Boards of three-quarters of an inch and one inch in thickness are generally used to take the place of lath and plaster, but Mackite is also made in the form of planks of all thicknesses and of hollow blocks of various sizes. Another good feature of Mackite is that it is not only a non-conductor of sound, but is readily and cheaply applied in the form of blind or intermediate floors, hollow partitions, etc., for purposes of sound deadening.

Mackite, being a non-conductor of heat, prevents the condensation of moisture on the inside of iron roofs. It is, therefore, specially adapted for electric light stations, and has been applied in such situations in a number of places. The accompanying engraving shows the manner of applying the Mackite board lining to a corrugated iron roof as built by the Berlin Iron Bridge Co. The fastenings holding the sheets of corrugated iron pass directly through the boards, securing them in place also.

THE THOMSON-HOUSTON MOTOR COMPANY, of Boston, have recently added a ventilating engineering department, and will use exclusively hereafter the Davidson fan, made by the Davidson Ventilating Fan Company, of Boston. This form of fan has been adopted after exhaustive tests, and will be used in conjunction with their own well-known type of motor.

SOLAR PRINTING FRAMES.

The Philadelphia Engineering Works, Limited, of Mifflin street, Philadelphia, have recently introduced an improved form of blue print frame, shown in the accompanying illustration, which possesses a number of valuable and distinctive characteristics. As will be seen, the frame is supported upon a single standard, occupying no appreciable floor space, and may be folded back against the wall when not in use. The frame is so mounted at the end of the supporting arm that it can always be placed in position to catch the rays of the sun in a direction normal to its surface at any hour of the day. It is strongly though lightly made of well-seasoned white pine, and will, no doubt, become deservedly popular.

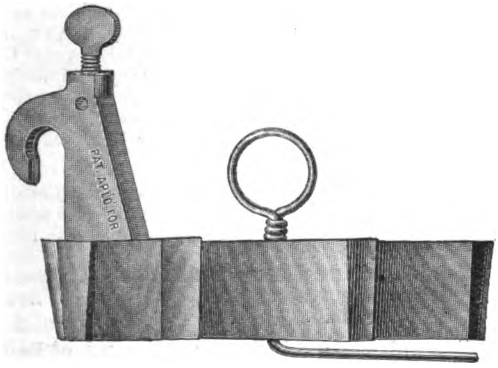


A Solar Printing Frame.

THE DELANY CROWFOOT ZINC.

The E. S. Greeley & Company have become the sole licensees for the manufacture and sale of the new zinc shown in this cut, the invention of Mr. P. B. Delany. The zinc itself is just like the ordinary crowfoot zinc in common use, but Mr. Delany has added a very simple and effective means for removal of the stalactite formations of spongy copper which grow on the under side and hang down into the copper solution, thus setting up local action and causing great waste of zinc and bluestone.

The device scarcely needs description. A glance at the cut will show a wire sweep through the central toe of the zinc. The wire is bent on a horizontal plane with the zinc, so that by touching the eye-end projecting above the solution the sweep is free to move in either direction so as to thoroughly sweep or brush the entire bottom of the zinc from centre to circumference, thereby sending all the spongy coating to the bottom of the jar. Heretofore this operation has been attended with so much difficulty that it was either imperfectly done or neglected altogether.



The Delany Crowfoot Zinc.

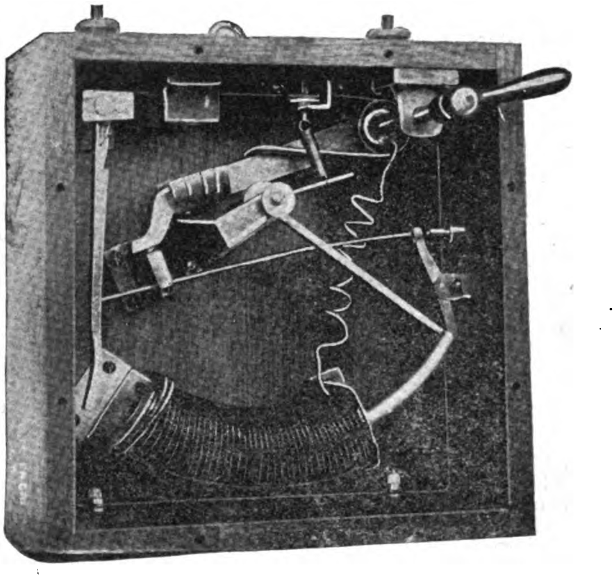
The careful battery-man or operator who has angled in a gravity cell with a piece of bent wire, smutching his fingers and twisting his neck trying to dislodge an inaccessible pendant, will welcome this simple improvement which will enable him to clean off a thousand zincs in a few minutes without splashing the shelves or his clothes. With this improvement it will not be necessary to disturb zincs from the time they are placed in the battery until entirely used up.

Besides the great saving effected in zinc and copper, the resistance and efficiency of all the cells of a battery will be uniform, as the laziest or most careless attendant will not fail to give the sweep an occasional twist.

As we understand that the nature of the device is such as to add little or nothing to the cost of the zinc, we see no reason why the Delany form of crowfoot zinc should not become a standard.

THE NEW DEAN AUTOMATIC CUT-OUT.

The accompanying illustration shows a new design in automatic cut-outs that has recently been designed by Mr. J. H. Dean, of St. Paul, Minn. The instrument is so arranged that the current passing through the solenoid attracts a core which is attached to an arm about which it swings. When the current exceeds a certain limit, the core is drawn into the solenoid, and raises a lever which in turn releases the switch and opens the circuit. If, as in the case of stationary motors supplied from central stations, the current is suddenly cut off when changing from one machine to another, the circuit is automatically opened by the tension spring. This engages the small lever by withdrawing the core from the solenoid and raising the lever, which in turn releases the switch. The tension spring is so arranged that it can be made to open the circuit for any predetermined amount of current. One of the main features of the cut-out is that it does away with all fuses, which are usually a large item in connection with central stations, and it may be relied upon to act at stated amounts of current. It can readily be applied to railroad circuits by using magnetic blow-outs at the switch contact. The cut-out has been given practical tests and found to work very satisfactorily in all cases.



The New Dean Automatic Cut-Out.

THE STORAGE BATTERY SUPPLY CO.

The above company are the agents of the Consolidated Electric Storage Co. of this city, and have offices at 120 Broadway, with works at 158 West Twenty-seventh street. They are making a specialty of supplying stored current for all purposes, whether for special or regular work such as running phonographs, automatic machines, small lathes, portable lamps, etc. We referred recently to a small portable lamp of theirs (page 205, of this volume), and are glad to refer to it again as a very handy little equipment. The lamp is encased with a glass shield, has a reflector, and derives current from the battery box on which the reflector is mounted. The business is under the active direction of T. D. Bunce, Jr., and R. S. Vorhees.

UNDERWOOD COTTON LEATHER BELTS.

Touching the Buffalo Convention, it should be noted that the Buffalo Street Railway Company's consolidated lines have just ordered three 24-inch Underwood cotton leather belts for their power station. These are in addition to the four cotton leather belts of same make and size now running at this station. These and other Underwood belts running in Buffalo were inspected and found to be doing exceedingly well. The Iroquois and Broezel hotels are equipped with them, and guests of these houses who were attending the Convention were shown the practical working value of the Underwood belting. The Buffalo belts were purchased through the Engineering Equipment Company, who have full control of the Underwood trade in New York State, from their offices, 143 Liberty street, New York City.

THE NEW V. V. CEILING PENDANT CUT-OUT.

ANOTHER new form of ceiling cut-out has recently been added to the long list of special and improved devices now upon the market. The article in question is a development of a design by Mr. J. Van Vleck, electrician for the Edison Electric Illuminating Co., of New York, for whose special requirements it was originally made. Mr. Van Vleck has succeeded in embodying in one block of small dimensions all the desirable features that such an appliance should possess.

The cut-out is adapted to both exposed and surface work. In the latter case the wires are brought directly through the base to the binding posts and do not appear on the outside of the cut-out. It has a square base and consequently is especially adapted to moulding work.

The interlocking contacts are substantially made and of such a character as to permit of no loose connections or the liability of the same working loose. Double-pole safety catches are concealed in the cover, permitting easy renewal without disturbing the base of the block, and the room for making connections is not cramped.

Possessing no external binding posts nor metal parts, the block has naturally found favor and received the endorsement of the Fire Underwriters. The block is known as the "V. V." ceiling cut-out, and a close inspection or trial will readily demonstrate that the claim of the manufacturers, the Interior Conduit & Insulation Company, that it is sure to meet with approval.

PHILADELPHIA NOTES.

MESSRS. J. W. PARKER & CO., Philadelphia, agents for the Ball engine and C. & C. motor, report the following installations: North Hudson Elevated Road, Hoboken, N. J., one 250 h. p. railroad Ball engine; Leesburg, Va., Electric Light Company, one 60 h. p. compound Ball engine; Doylestown Electric Light Co., Doylestown, Pa., one 125 h. p. standard Ball engine. C. & C. motors—Edgemoor Bridge Works, Wilmington, Del., one 15 h. p. special motor; Wm. Sellers Co., Philadelphia, one 7½ h. p. special motor; Winifrede Coal Co., Winifrede, Va., one 8 h. p. special motor; Delaware Electric and Supply Company, Wilmington, Del., one 5 h. p. motor; Sternberg & Co., Philadelphia, one h. p. motor; Novelties Mfg. Co., Philadelphia, one 2 h. p. motor; Harding & Dubois, Philadelphia, one 7½ h. p. motor; Assembly Building, West Chester, Pa., one 1 h. p. motor.

THE ISOLATED LIGHTING DEPARTMENT of the Thomson-Houston Electric Co. has been merged with the general department of that company in order that it might bear the same relation to that company that the other lines of electric work enjoy. All isolated work is now conducted through the general department. Mr. C. K. Westbrook, the former manager of the isolated department, still remains with the company in the capacity of salesman in both central station and isolated work.

THE LA ROCHE ELECTRIC WORKS have just issued a handsome catalogue of over 50 pages, finely illustrated and giving a full description of their arc and incandescent lighting machinery and instruments which they make in large variety. It also gives many testimonial letters from those who are using the La Roche system.

THE RIES ELECTRIC SPECIALTY CO., of Baltimore, are driven to their utmost capacity in filling orders for their regulating sockets. They have just established an agency at Helsingfors, Finland, Russia, and are communicating with parties in different countries, all of which is the result of their advertising in THE ELECTRICAL ENGINEER

MR. ARTHUR L. BOSLEY, of the Pennsylvania Electric Engineering Co., and Miss May A. Turner were married last week at the home of the bride, 1924 Girard avenue. Owing to the recent death of the bride's mother, none but the immediate family was present. Mr. Bosley and bride are making an extended tour North.

MR. EDWARD R. GRIER, formerly of the expert department of the Thomson-Houston Electric Co., of Lynn, Mass., has opened an office at 501 Girard Building. Mr. Grier will make a specialty of construction work, and will also act as agent for several well-known manufacturers of electrical supplies.

MR. F. A. LA ROCHE, general manager of the La Roche Electric Works, has recently returned from a three weeks' business trip through the West and South to Cuba. Mr. La Roche closed some important contracts during his absence and reports a bright outlook.

W. H. WESTON & CO. have just finished some very fine switchboards, among which was one for the Tucker Electrical Construction Co., of New York, and several for a concern in Maine. The demand for their railroad switches continually increases.

THE WASHINGTON ELECTRIC CONDUIT CO. have orders for their terra-cotta conduits to be laid in Washington alone which will amount to over $50,000. Several other cities have adopted the terra-cotta conduits.

THE PENNSYLVANIA ELECTRIC ENGINEERING CO. has just closed a contract with the Milville (N. J.) Electric Light Co. for a 500-light National alternating dynamo.

NEW ENGLAND NOTES.

THE COMBINATION CAR COMPANY, of 23 Court street, Boston, was organized some time ago for the purpose of manufacturing a combination car; or, in other words, a car which would be suitable either for winter or summer purposes. At present street railway companies are obliged to have two sets of cars, one for winter and another for summer use, which necessarily involves a large expenditure of capital, not only for the cars themselves but for their storage when not in use. The combination car is instantly transposable from a winter to a summer car, by means of an ingenious system of windows, which can either be opened or closed. The seats are all placed across the car, and access is had to them by a passage running up the centre of the car, so that passengers require to get on and off at the ends, which is a decided advantage, as it eliminates all danger from stepping off in front of an approaching car. One of these cars is now nearly ready for use, and will soon be seen in the streets of Boston. The company's officers consist of Mr. Frank Chandler, president; Mr. Wm. H. North, vice-president; Mr. Gilman B. Bolton, treasurer, and Mr. G. C. Hoyt, secretary.

THE AMERICAN CIRCULAR LOOM COMPANY, of Boston, have recently added to their justly-celebrated product of canvas-jacket wires, the manufacture of a flexible tubing for interior wiring which seems to have great merit, and was fully described in a former issue of THE ELECTRICAL ENGINEER. They have lately been experimenting, with very flattering results, with the same tubing, protected with a lead covering, for underground and submarine work, and seem to be in a fair way of obtaining what everyone is looking for—a cheap and efficient underground conduit.

S. C. NIGHTINGALE & CHILDS, of Boston, Eastern agents for the Magnesia Sectional Covering Company, of Ambler, Pa., have received a contract for covering the steam pipes, etc., of the new electric light station at Brookline, Mass., and will also cover with magnesia all the new pipe-work now being installed in the station of the Boston Electric Light Company. They are also covering the four Manning boilers and the cylinders of the Greene compound engine, now being installed by the Thomson-Houston Company, at Lynn, for testing their large power generators.

THE BOSTON BRAID MANUFACTURING COMPANY, of 28 Beach street, Boston, are making a specialty of fine silk braid for the manufacture of filaments for incandescent lamps, and have scored a decided success in this line. Quality and uniformity are absolutely indispensable, and Mr. Fieldler, the general manager of the company, reports that judging from the demand for his goods, they appear to have given the highest satisfaction.

THE RHODE ISLAND BRAIDING MACHINE COMPANY, of Providence, R. I., have recently supplied the Electric Supply Company, of Ansonia, Conn., with several of their heavy double-deck wire-covering braiders, with a special take-up arrangement for winding up heavy wire. They have also supplied recently several of their special taping machines to various manufacturers of insulated wires.

MR. F. L. LENOIR, superintendent of the Worcester Consolidated Street Railway, reports all but twenty-one miles of the entire road equipped, and work on this is progressing rapidly. He has just returned from a short Western tour of inspection. The Worcester, Leicester and Spencer Railway have recently added a 100 h. p. multipolar generator, which works with five bi-polar dynamos of 80 h. p. each.

THE THOMSON-HOUSTON ELECTRIC COMPANY, of Boston, have recently received the order from the Brooklyn Street Railway Company for 600 complete car equipments, comprising 1,200 motors in all.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XIII. MARCH 16, 1892. No. 202.

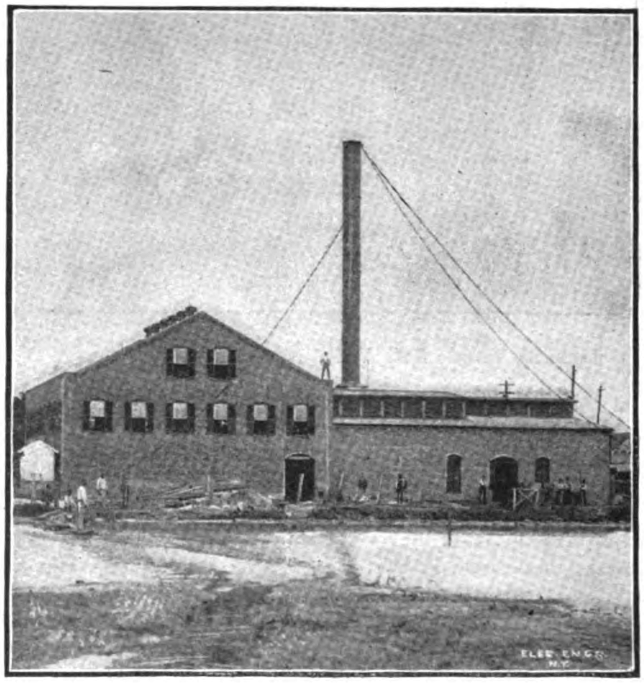
ELECTRIC LIGHTS ON A CORAL REEF.

Part of the Staff.

THE installation of an electric light plant at Key West, Fla., has attracted considerable attention in electrical circles, from the fact that it is the southernmost plant in the United States, and is built on a coral reef. Key West lies in lat. 24° 32′; a mere speck of rock begirt by the blue waters of the Gulf, almost unknown to the rest of the world, and the very end of the United States. The Key has been settled about seventy years, and during that time has grown from a small hamlet of fishermen to a city of 23,000 people. The inhabitants consist of Cubans, negroes, Conchs and Americans. The Cubans are cigar makers; Conchs, sponge fishers and wreckers; and the negro, with his elastic make-up, covering a wide range of occupations, some of them useful mechanics, a few utilized as policemen, while a large majority do an immense amount of arduous "sitting around." The Americans are endeavoring to lift the city out of the old-time rut by improving the condition of things in general.

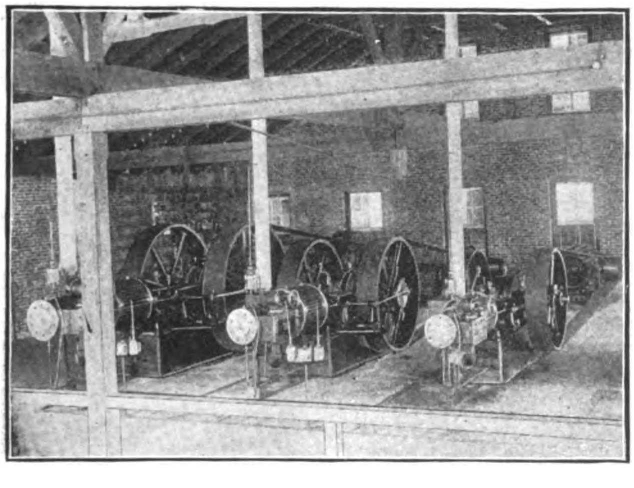
Through the efforts of the latter class of citizens, the lighting of the town in a civilized manner has been accomplished. Some years ago a franchise was granted, and a company formed known as the "Key West Gas and Electric Company," who erected a small gas plant, using petroleum, from which gas was manufactured. This went into operation in 1884. The question of installing an electric plant was brought up from time to time, and in order to hold the franchise a few poles were set. Through the efforts of Mr. John Jay Philbrick, a local merchant, an extension of time was granted, and, after buying up nearly all the shares of the company and making a careful examination of the different systems of electric lighting, Mr. Philbrick, in the early part of 1891, gave the Thomson-Houston Electric Company, through their Atlanta agent, Mr. Hiram Ogle, an order for the electric plant, and the Ball Engine Co. of Erie, Pa., for the steam plant. The lighting plant called for was one 50 light 10 ampere arc dynamo, with lamps of 2,000 c. p.; one 650 light, and one 1,500 light compound wound alternating dynamo, for lamps of 16 c. p. with all the necessary appliances and fixtures.

The steam plant consists of three Ball condensing tandem compound engines of the latest improved pattern, one of 65 h. p., one of 110 h. p. and one 165 h. p., one Otis heater of 300 h. p., one Wheeler surface condenser of 300 h. p., one Davidson air pump and fresh-water pump, one Keating injector, two steel boilers 150 h. p. each. A brick building, 62 x 45 feet, was erected in which to place the machinery. But here the first difficulty presented itself. A pit 10 feet deep was required for the heater, condenser and pumps, but this was found impracticable on account of the friable nature of the coral rock, through which the water bubbled up without interruption. It would require a powerful steam pump to keep the pit clear while it was being dug, and costly masonry to keep the water out after it was dug. The rock could only be worked with pick and shovel; blasting had but little effect on account of it being very soft and offering no resistance. The plans were changed. An additional brick building, 80 x 60 feet, was built, in which the engines and dynamos were placed on foundations 10 feet high, of hard brick, resting on the coral rock, and with a small amount of earth filling, making a solid mass of masonry 36 x 40 feet and 10 feet high. On the top of this mass of masonry and earth filling was spread grouting of broken stone and cement six inches thick, and finished with a graniteoid floor 1¼ inch thick. This brought the heater, condenser, pumps and hot-well on a level with the floor of the first building (which was used for a boiler house) between the engine foundation and partition wall. In front of the condenser a salt well, 18 x 18 feet and 5 feet deep was dug in the rock, from which the water supply for the circulating pump was drawn. From this to a salt-water pond, on Government land 100 feet west of the station, a canal was dug through the rock to the pond, which covered about three acres and was connected with the sea. The depth of water in the pond was 13 inches at low tide. Spread over the bottom of the pond was 23 inches of silt. A channel 10 feet wide was dredged through the pond and the inlet from the sea deepened. A tide gate placed in the inlet allowed the tide to enter



POWER HOUSE; KEY WEST ELECTRIC LIGHT PLANT.

the pond and closed on the ebb, giving a depth of about 25 inches of water at low tide, an ample supply for condensing purposes. The top of the boiler house floor was but 23 inches above the high-water mark located on the beach. While digging the salt-water well the water ebbed and flowed with the tide, although over 100 feet of rock lay between the well and pond which was affected by the tide. The distance from the station to the sea proper was 1,100 feet. There is no fresh water on the island except what is collected from the roofs, stored in stone cisterns and sold at one and a half cents per gallon. As no cistern had been built for the use of the station, and it was necessary to have enough fresh water to make up for the waste and fill the boilers after cleaning, the engineer made an examination of the brackish water which could be drawn from the rock at a depth of from three to five feet, and as this water was used for domestic purposes by those who had no cisterns, he concluded to use it until a cistern could be built. It was found that the rock was filled with water from rains, and held back by the dense sea water surrounding the island, and at a level somewhat above the tide marks, ebbing and flowing with the tide. A well four inches in diameter was drilled into the rock and the water tested for salt every foot. At a depth of 20 feet a slight change was noted and the drill stopped. A pipe 18 feet long was dropped in for suction and the boilers fed from this when occasion required. A trace of salt was perceptible in the water, but on the whole it was superior to water used at many places on the main land for boilers. In a trial of two hours' duration, the pump delivered a solid stream through a 1½-inch nozzle without diminishing the supply, showing conclusively that the water flowed through the rock as readily as through gravel. Although a small quantity of this water was used for boiler fuel each day, some scale was looked for, but after twenty-one days' run the boiler was opened and found perfectly free of all earthy deposit, and with the exception of a small amount of oily matter along the water line as clean as when put in service. The fuel was Cumberland coal.



DYNAMO ROOM; KEY WEST ELECTRIC LIGHT PLANT.

The arrival of the machinery was an event in the history of Key West, and was viewed with great curiosity as it came over the steamer's side. The landing of the big boilers created much excitement among the natives, who at once began to speculate on the manner of transportation from the wharf to the station nearly a mile away. Heavy teaming was unknown, consequently there was no truck strong enough to carry the boilers, on the island. They were therefore placed on cradles mounted on skids, and trundled very slowly—about half a mile a day—through the streets on rollers, with the aid of a tackle and a pair of mules. Previous to the arrival of these engines and boilers, the entire steam power on the island amounted to about 15 h. p.

The poles used for the line are cypress, shipped in from Tampa by vessel. As the island is a mass of coral rock, all holes for the poles, with the exception of places once a salt marsh, and now filled in, were dug with steel-pointed bars; costing from seventy-five cents to two dollars each, according to the hardness of the rock. Layers of flint were often struck, and where this occurred an entire day was often consumed in getting one hole down to the required depth. In the lower part of the town which was at one time a salt marsh and filled in, the earth was too soft to hold the poles, and the tide flowing in the gutters of the streets, kept the ground soaked. Barrels were sunk in which the poles were placed, and broken stone was tamped in. The lower end of the poles was coated with asphaltum, and the remainder painted. Twenty-five lightning arresters were placed in different parts of the lines. Kite-flying is one of the amusements, and indulged in as much by grown persons as by youngsters, and in a short time the lines were festooned with all manner of kites and kite-tails, and for blocks at a stretch the wires were pulled together. An ordinance was passed by the city council imposing a fine of $5 against kite-flying, and the police were instructed to arrest all violators. A short time before the plant went into operation, men were sent out, and the lines were cleared. Many schemes were tried to remove the wrecked kites, but the most effective was with a torch on the end of a long pole.

On December 24th last, the engines turned over for the first time. It had been announced some weeks previously that the town would have the lights on Christmas Eve; and a large crowd of people gathered at the station to see if it was possible to make a lamp burn without oil, and with a wick that looked like a piece of iron. At seven o'clock the engines were started, five minutes later the switch was turned, and in an instant the station was in a blaze of light, while cheer after cheer went up from the motley crowd. The light was at once popular, and orders came in so rapidly, that the line force was increased, and lines were extended as fast as possible. The street lighting has been done by private subscription. The price for arc lights is $4.50 and incandescent lamps are fifty cents per week, all-night lighting. The plant has cost about $70,000. It was installed by Mr. H. P. Loring for the Thomson-Houston Co. and Mr. C. W. Hanson for the Ball Engine Co. Almost the entire expense has been borne by Mr. Philbrick, through whose efforts Key West has one of the finest electric plants in the South, and the lighting of a coral reef has been accomplished.

DIELECTRIC HYSTERESIS—THE LOSS OF ENERGY IN A DIELECTRIC MEDIUM UNDER ALTERNATING ELECTROSTATIC STRAIN.

BY

Chas. Steinmetz.

IN a paper read before the American Institute of Electrical Engineers on January 19, 1892, I have proved by experimental data, that the loss of energy in iron and other magnetizable bodies, under alternating magnetic strain, is expressed by the formula,

$$H = \eta B^{1.6},$$

that is, proportional to the 1.6th power of the intensity of the magnetic field.

The analogy existing between the behavior of dielectric bodies in an electrostatic field with that of a magnetic body in a magnetic field suggested that in dielectric media in an electrostatic field, for instance in the insulating medium of a condenser which is alternately charged and discharged, a consumption of energy takes place, which depends upon the intensity of the electrostatic field according to a law similar to that of magnetic hysteresis.

That in the dielectric medium of a condenser, which is connected with an alternating E. M. F., a consumption of energy takes place, is known from the fact that the condenser gets hot, while it does not get hot when connected to a source of equal, but constant potential.

To determine this loss of energy and its dependence upon the E. M. F. I made, towards the end of January, 1892, a number of tests with a condenser of 3 microfarads capacity, with paraffine paper as insulating medium, by connecting this condenser in an alternating current circuit of 170 complete periods per second, and measuring the energy consumed by the condenser, in a similar manner, and with the same apparatus that was employed in the tests on magnetic hysteresis.

After subtracting the energy consumed by the leakage current—which was found by testing with a continuous current of equal E. M. F.,—and the energy consumed by the instruments, it was found that:

The energy consumed by the dielectric medium under alternating electrostatic strain is directly proportional to the SQUARE *of the intensity of the electrostatic strain; that is, proportional to the* SQUARE *of the* E. M. F. *acting upon the condenser;* or, expressed in symbols,

$$H = k E^2.$$

Hence, while the *magnetic hysteresis* follows the law of the 1.6*th power*, the *dielectric hysteresis* follows a simple *law of squares;* that is, it acts just the same as a mere dead resistance connected into the circuit.

The tests covered the range from 80 volts up to 320 volts, and agreed very nicely with the law of the square.

Beyond 320 volts the dielectric medium apparently began to give way, and the energy-consumption increased faster than proportional to the square of the E. M. F. That was still more marked in a second set of observations, made right after the condenser was overstrained. Here the deviation from the law of squares began even at a lower E. M. F., and the energy-consumption increased so rapidly with increasing E. M. F., that the tests had to be interrupted.

In a third set of tests, on the next day, the dielectric had somewhat recovered; the energy-consumption remained proportional to the square of the E. M. F. up to about 250 volts, then increased more rapidly, and then suddenly increased very much, while the E. M. F went down, and a hissing noise was heard in the condenser; it had given way.

From the above we derive the conclusion, that up to an E. M. F., at which the dielectric begins to break down, the energy-consumption in the dielectric of a condenser is proportional to the square of the E. M. F. acting thereupon.

ECONOMY IN ARC LIGHT WIRING.

BY

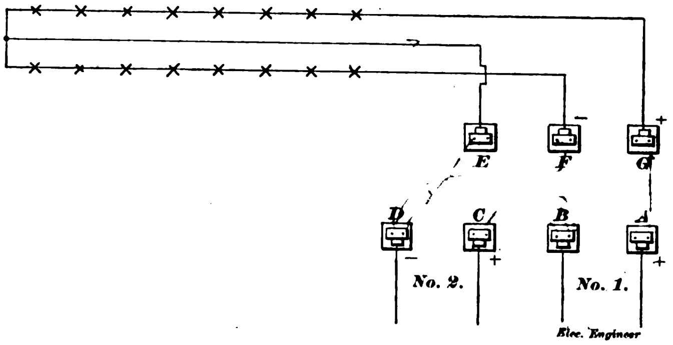
S. H. Sharpsteen

THERE are many towns throughout the country that have from 50 to 80 arc lamps and possibly many to be installed, of about the same number. Continuous service with a small amount of copper, with certain amount of loss of energy allowed, are important questions. If the town is long and scattered, copper will be a large item and must be used as economically as possible.

The first thing usually done is to put both municipal and commercial lamps on the same circuit, possibly with one large machine. The work is done in a hurry and the towns-people think with the stockholders and directors, possibly, that the plant shows much engineering skill. Fall comes with its long nights and the superintendent finds that he has got to burn his street lamps much longer, by far, than there is any need of. The final result is that another circuit has got to be run, the commercial lamps put on one, and the municipal lamps on the other.

About three years ago I adopted the following method and have found it to work well: By referring to the figure one can see that all the arc lamps were put on two legs of wire; the commercial lamps on one leg marked G and the municipal lamps on leg marked F. A third wire was started from a switchboard terminal E just to the left of the other two and run out on the pole-line until it came to the last commercial lamp and was there connected to the leg containing the commercial lamps.

The circuit went on some distance farther containing municipal lamps, but all that was necessary was to run past the last lamp of either leg. In the case referred to here there were two machines worked in series the switchboard terminals of one being C and D, and of the other A and B. Since the two were driven from the same countershaft with friction pulleys, when the commercial lamps were wanted, machine No. 1 was started and by means of the usual cables and plugs A and G were connected together; and also B and E; the result was that the commercial lamps were lighted.



PLAN OF CIRCUITS FOR ARC LIGHTING.

Later on when it was dark enough to want the street lamps, machine No. 2 was started, the brushes put down at point of minimum working capacity when by means of the remaining hole in the terminal B, the latter was connected with C; and by means of the remaining hole in E, E was connected with D. The result was that machine No. 2 was in circuit with no load and if brushes were not at the point above referred to they would burn. The next thing in order was to disconnect E and B, which put both machines on the commercial circuit. Now to get E out and F into circuit, one plug of the cable just taken off from the switchboard was put into the remaining hole at D. The other plug was put into the right hand and held near F until the plug in E was withdrawn far enough to draw a short arc, when the plug held in the right hand was put into one of the holes in F, when the arc at E let go and both lamp legs were on both machines. In this connection one might say, "Why not leave plug in E until plug is into F?" This would be all right if machines were automatic in regulation, but if not, the current would be apt to increase in quantity since there would be two paths for the returning current and resistance decreased. One good feature of having two machines is to make partly sure of always having the commercial circuit working. In case of an accident or some little thing occurring that causes the shutting down of one machine the other machine can be made to work the commercial lamps alone.

MR. TOMPKINS, superintendent of the Berkshire Electric Co., is spending the winter in California.

INSULATED ELECTRIC CONDUCTORS.[1]—I.

BY

James Bowstead Williams M.D.

Chapter I.

In San Francisco, in 1886, during a conversation with a friend relating to electrical matters, the question was asked, "Isn't it possible to invent *some* means by which the escape of the current from telegraph lines can be lessened, or even prevented?" The speaker then added: "When I was an operator in Arizona, we had a great deal of trouble with our railroad lines during certain seasons of the year, and at times could not communicate with cities in California." As my attention had never been directly called to this matter before, these remarks caused me to wonder whether or not something could be invented which would prevent the escape of the electric current from the line to the glass insulators; for my experience of glass as an insulator, in 1868—during which year I made a frictional machine, the cylinder of which was a large bay rum bottle—and some years later, while making and using Ruhmkorff coils, had taught me that glass could not always be depended upon to insulate electric currents, particularly high tension currents, on account of the deposition of moisture upon its surface during certain atmospheric conditions.

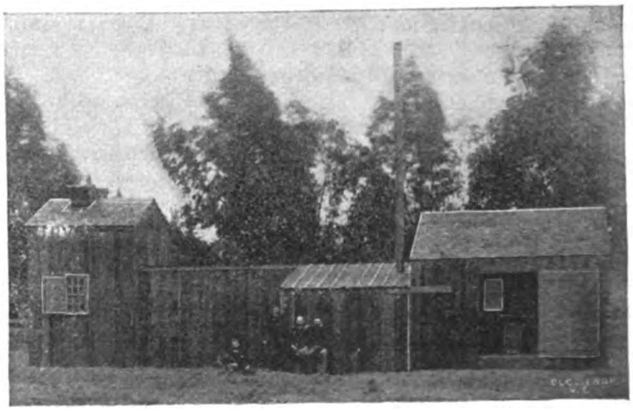
I considered this matter for several days, when the thought occurred to me, "Why not, instead of simply trying to discover a better way of insulating telegraph wires than by the use of the ordinary glass insulators, institute a thorough examination of all obtainable insulating materials and endeavor to produce compositions for the efficient insulation of *all* kinds of electric conductors?" And the longer I considered the matter, the more determined I was to begin the examination.

At that time it was generally supposed that "Underwriter's Wire"—since very appropriately called "Undertaker's Wire"—was good enough for all ordinary purposes; and remarks somewhat similar to the following were made to me by parties who were supposed to know something about insulation:—"Why hunt for anything better than underwriter's wire? For if it were *not* good enough why do you suppose underwriters would recommend its use?" "Its universal use is proof enough of the value placed upon it." "What we need the most is a wire which will not allow fire to run along its surface." I was not discouraged by such remarks, however, but began to devote all the time I could spare from my practice to the study of the subject of insulation; read all of the United States and English patents relating to the subject; consulted text-books, reports of English committees, and other literature in the libraries; and realizing the commercial value of highly insulated wires and cables, I decided to commence active work at once. But before commencing my investigation I readily saw that special testing apparatus would be required, in order to enable me to rapidly determine the comparative insulation resistances of *short* pieces of highly insulated wires. I therefore designed and made a modified form of Sir William Thomson's quadrant electrometer, with replenisher and gauge in a separate vessel, together with the necessary discharge key and other necessary adjuncts; and since then I have never regretted the time spent in making them. This testing outfit will be illustrated and described in a subsequent article.

After providing myself wiith these testing instruments, I obtained samples of all the insulated conductors I could procure, and insulating material of various kinds, and began the practical study of the insulation of electric conductors. My first "mixing rolls" consisted of a marble slab, heated over a coal oil stove, and a stout wooden spatula, with which I succeeded in mixing several rubber compounds. For compositions combined directly by means of heat, *i. e.*, while in a melted state, I used agate ware saucepans; and for those combined by means of solvents, double-chambered vessels and evaporating dishes. My first "tubing machine" I made of brass tubing, and provided it with a piston which was operated with a strong screw and handle, and the necessary dies with their centering and adjusting devices. By means of this tubing machine I was able to cover wires with compositions which were readily rendered plastic by heat. My first experiments in vulcanizing were performed with a dental vulcanizer.

One of the first pieces of wire which I insulated with a rubber compound I still have; and its insulating layer, although exposed to air, moisture, etc., for nearly five years, and mixed and applied in the crudest manner, still retains its insulating properties apparently unchanged.

Encouraged by my first efforts, and seeing the necessity of more fully investigating the subject, and also of having suitable machinery, I informed a former schoolmate and friend, Dr. James L. de Fremery, of my researches and work, who, after seeing the results I had already obtained, generously informed me that the necessary funds should not be lacking to make a most thorough examination of all obtainable insulating materials and methods of using them; and he has my sincere thanks for both his moral and financial backing. I then gave up my practice as a physician and visited Eastern cities, in April 1887, for the purpose of purchasing machinery, materials to experiment upon, insulated wires, and whatever else was necessary for the work. Immediatly after my return to California, the laboratory, a photograph of which is shown in the accompanying illustration, was built in Oakland, and equipped with the necessary machinery, a portion of which was obtained in the East, and the remainder either made in my workshop or by others after designs of my own. The atmosphere in and about the laboratory was continually charged with moisture and gases from marshes which lay between the laboratory and San Francisco Bay, and oftentimes with sewer gas. The trade winds, with their accompanying fogs, which often last from March until November, blew directly across the marshes from the Pacific; and nearly every night during a portion of the year the lower part of the building was enveloped in a thick mist. So great was the amount of moisture *always* present in the atmosphere that we were obliged to keep the machinery covered, except while in use, with a layer of thick petroleum, in order to prevent its rusting; and even the petroleum (18° B.) was not proof against the effects of the moisture and various gases, but had to be renewed every few days.



Laboratory for Testing Insulated Wires.

These facts are stated to show what severe conditions, purposely chosen, the insulating materials were subjected to during their examination and use; and it was owing to these conditions that we were often enabled to observe the effects of moisture, gases, etc., upon the different materials, simple and compound, in a few hours instead of having to wait for days or weeks, as would have been the case had the work been carried on under favorable conditions.

---

[1] *Copyrighted* 1891, *by James B. Williams, M. D. All rights reserved.*

Throughout the entire work in California, both in laboratory and factory, which occupied more than three years' time and at an expenditure of several thousand dollars, I was ably assisted by my brother, Mr. Rufus W. Welty, who was of the greatest service to me, particularly in the setting up and management of machinery, and in designing and making new forms of the same. Whenever the work was of such a nature that additional help was necessary, I employed from one to four others, as occasion required.

Having written this somewhat long introduction, the different kinds of material experimented upon will be enumerated, and a description of the various ways in which they were used and examined, and also of the electrical apparatus employed in testing the same, will be given; after which the writer will endeavor to set forth, in simple and concise language, and probably for the first time, how all kinds of insulated electric conductors can be manufactured for use, from the selection and preparation of the materials with which the metallic conductors are covered, to the finishing of the insulated conductors and protection of the same, including descriptions of the machinery used, and the processes employed, in their production; and to the above will be added, from time to time, as occasion requires, other items of importance relating to the subject of insulation which have been obtained from laboratory and factory practice. As all insulated conductors now in general use may conveniently be divided into types or classes, but one example of each type will generally be selected for illustration; and these types will be referred to as types 1, 2, 3, et seq., except the inexpensive types—such as magnet wire, weatherproof wire, etc., —which will be called by their proper names. In addition to the types above mentioned, illustrations and descriptions of some new forms of insulated conductors invented by the writer and secured by letters patent of the United States and foreign countries will be given.

It is evident to any one familiar with the manufacture of two or more types of insulated conductors that, in treating of a subject embracing the details of the manufacture, etc., of more than a dozen types, repetitions of such details are unavoidable; but, unless necessary to a proper understanding of the subject, they will be made as few in number as possible. The principal substances examined in laboratory and factory were india-rubber and gutta-percha; resins and gum resins, such as colophony, copal, amber, shellac, pitch, etc.; paraffines and paraffine oils; coal tar and its asphaltum; petroleum, asphaltum, and other petroleum products; vegetable oils, such as linseed, cotton seed, etc.; fibrous material, including paper, parchment, jute and cotton and silk; and several mineral substances, such as asbestos, silica and silicates, lead and zinc salts, lime, etc. These substances and many others were examined singly, whenever they could be so examined, and in suitable combinations (oftentimes unsuitable combinations) of two or more. The total number of combinations exceeded five hundred; and the methods of combining the substances, applying them to conductors and testing them, and the apparatus with which they were electrically tested, will now be described in the following chapters.

"DIE ELEKTRIZITAET."

A NEW semi-monthly periodical with this title, the organ of the Leipziger Elektrotechniker-Verein, has just made its appearance. There are a number of electrical societies springing up in Germany.

AN ELECTROLYTIC WATTMETER.

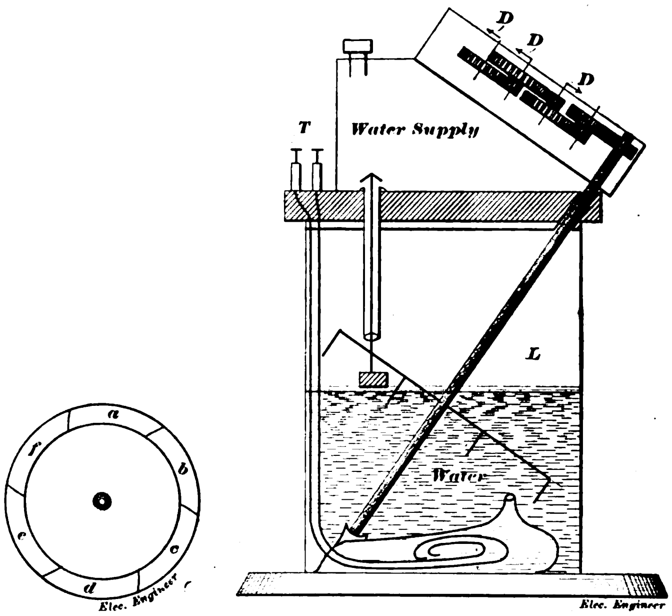
BY

F. A. LaRoche

PERHAPS no subject of inquiry has received more attention from the electrical mind than the production of a satisfactory wattmeter. Of the many valuable achievements in this direction it is safe to say, that not one embraces all the features of the ideal instrument. It is not claimed that the device here described even approaches the ideal; but one sterling virtue recommends it to notice. While on minor counts, it is quite possible to excel the instrument under discussion, yet in point of accuracy it stands eminently superior. Every little variation of current is noted and summed up in the final registration with unfailing fidelity.

For its action this meter depends upon the electrolysis of water. The principle is not new, but in the method of its application lies the originality and usefulness.

The whole mechanism is contained within a circular glass jar covered by a loosely fitted lid; this jar is about eight inches in length and six in diameter. Inside and upon the bottom of the jar is placed a circular receptacle; this addition is also of glass, and provided with a rim that raises it from the bottom of the jar leaving a hollow space one inch in height. Within this enclosure the terminal wires are placed, and the gases liberated. The top of this enclosure is slightly convex but rising higher near the circumference on one side, and terminating in a conical elevation. Through an aperture in this cone the gases escape to be measured and accounted for.



FIGS. 1 AND 2.—LA ROCHE ELECTROLYTIC WATTMETER.

The construction of the apparatus will be clearly understood by reference to the accompanying illustrations.

Fig. 1 represents a disc of vulcanite, the rim of which is divided into six equal compartments, *a*, *b*, *c*, *d*, *e*, *f*, that are raised upon one side of the disc. These divisions form cups about one inch in depth, and the same in width, each entirely separate and gas tight. Through the centre of the disc is secured a shaft consisting of a long, pointed glass rod upon which the whole is intended to revolve.

Fig. 2 represents a vertical section of the meter ready for use. In this figure will be observed the disc and rod in position, the cups opening toward the bottom of the jar, and the lower edge of the disc immediately over the cone from which escape the gases before mentioned. When the jar is filled to the level L, Fig. 2, with a mixture of sulphuric acid, one part, and 10 parts water, and the current passed through the terminals T, the following results ensue:

Water is decomposed into its elementary constituents oxygen and hydrogen. These gases collect in the top of the enclosure at the bottom of the jar from whence they escape through the opening at the apex of the cone C. The position of the disc is such that all of the escaping gases is collected within the inverted cups.

It will be observed that the disc is inclined at an angle of about 45 degrees. This is necessary to secure the desired end. As the gases fill the cups the upward pressure increases, causing the disc and shaft to gently rotate upon the point.

As each cupful of gas reaches the summit during the rotation and commences to descend upon the other side, the gases escape and the cups again fill with water. Thus the operation is repeated as long as the current passes. From the end of the inclined shaft the record is carried through a train of gear wheels to the several dials, D, Fig. 2, from which the readings are taken.

This apparatus is very simple in its construction but a number of precautions are necessary to insure its accuracy. The liquid must be kept at a constant level within the cell. This is accomplished by placing a reservoir over the top of the jar with a supply pipe that is closed automatically, when the liquid reaches the proper level.

The terminal connected to the positive wire should be made of platinum foil, otherwise the nascent oxygen would speedily destroy it. The negative, however, may be made of sheet lead, as hydrogen is liberated here and is not attended with any corrosive action.

There is but one possibility of a perverted record with this instrument and that would be brought about by the expansion of the gases, provided the temperature should rise unusually, but even here the discrepancy is more theoretical than real. When we remember that gases expand but $\frac{1}{492}$ of their bulk for a rise in temperature of one degree, the consideration becomes insignificant as practical demonstration has proven.

THE PRACTICAL MANAGEMENT OF DYNAMOS AND MOTORS.—VII.

BY

Francis B. Crocker and S. S. Wheeler.

CHAPTER IV.—*Continued.*

Constant Current Motor.—The commonest example is a series wound motor on the arc circuit. The connections are shown in Fig. 19. The switch 1 is to entirely disconnect the circuit from the building in case of fire or other emergency. By simply turning the other switch 2 the motor is started or stopped, and since the current is constant the motor may be overloaded or held still without injury, whereas a constant potential motor would burn out. The precaution necessary is never to touch the machine with current on, as the E. M. F. is probably high and very dangerous. Turn off the switch to fix the machine. A constant current motor should be provided with an effective centrifugal governor for controlling the speed, otherwise it will run away when the load is taken off, like a series motor on a constant potential circuit.

Alternating Current Motors.—These have not been very extensively used up to the present time, although a great variety of forms have been tried or suggested. Alternating motors are required to run on constant potential circuits since almost all alternating current systems are of this kind. But with alternating current there is no trouble from the rush of current which tends to occur in starting a motor with a constant potential direct current, because the self-induction of the field and armature coils prevents it. There are several types of alternating current motors. The simplest of these is a plain series or shunt machine the same as for direct current, except that the field magnet is laminated as well as the armature. The trouble with this type, which has been used commercially in small sizes, is that bad sparking is apt to occur when the brush passes from one commutator bar to the next and short circuits a coil which has alternating currents generated in it by the reversals of the field magnetism. An ordinary alternating current dynamo can be used as a motor but its speed must be brought to agree with the current alternations before it will run, and then if it loses this exact speed it stops, and is therefore unpractical. In the Tesla and other similar motors the effect is obtained by a rotary current, but this requires two or more currents of different phase and usually a special three-wire system would have to be put in before such motors could be operated.

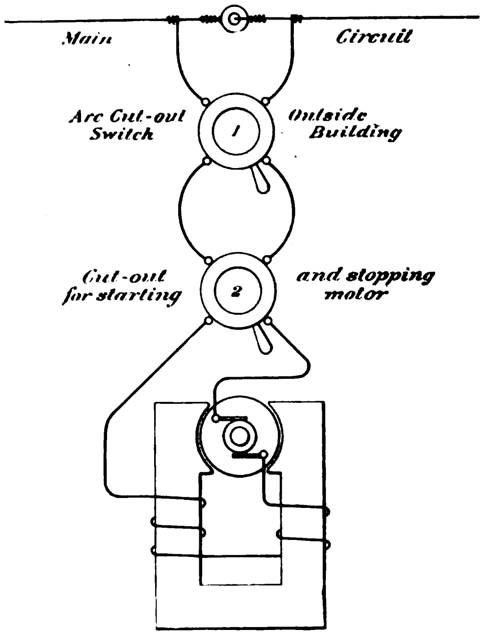


FIG. 19.—SERIES MOTOR ON CONSTANT CURRENT CIRCUIT.

CHAPTER V.

DIRECTIONS FOR RUNNING DYNAMOS AND MOTORS.

After one of these machines has been properly started as described in the previous chapter, it usually requires very little attention while running, in fact a dynamo or motor frequently runs well all day without any care whatever.

In the case of a machine which has not been run before or has been changed in any way, it is of course wise to watch it closely at first. It is also well to give the bearings of a new machine plenty of oil at first, but not enough to run on the armature, commutator or any part that would be injured by it, and to run the belt rather slack until the bearings and belt have gotten into easy working condition. If possible, a new machine should be run without load or with a light one for an hour or two, or several hours in the case of a large machine, and it is always very objectionable to start a new machine on full load.

This is true even if the machine has been fully tested by its manufacturer and is in perfect condition, because there may be some fault in setting it up or other circumstance which would cause trouble. All machinery requires some adjustment and care for a certain time to get it into smooth working order.

When this condition is reached the only attention required is to supply oil when needed, and see that the machine is not overloaded. The person in charge should always be ready and sure to detect any trouble such as sparking, the heating of any part of machine, noise, abnormally high or low speed, before any injury is caused and to overcome it by following the directions given in the chapter devoted to these troubles. Those directions should be pretty thoroughly committed to mind in order to facilitate the prompt detection and remedy of any trouble when it suddenly occurs as is apt to be the case. If possible the machine should be shut down instantly when any trouble or indication of one appears, in order to avoid injury and give time for examination.

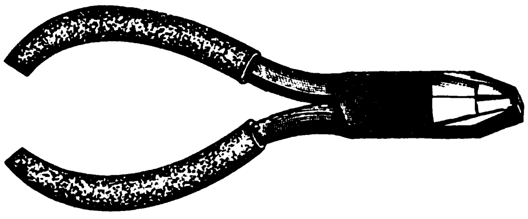

FIG. 20.—TOOL INSULATED WITH RUBBER TAPE OR TUBING.

Keep all tools or pieces of iron or steel away from the machine while running, as they might be drawn in by the magnetism and perhaps get between the armature and pole-pieces and ruin the machine. For this reason use a zinc, brass or copper oil-can instead of iron or "tin" (which latter is merely iron coated with tin).

Never lift a commutator brush while machine is running as it might make a bad burnt spot, unless there is one or more other brushes on the same side to carry the current.

Touch the bearings and field coils occasionally to see that they are not hot. To determine whether the armature is running hot, place the hand in the current of air thrown out from the armature by centrifugal force.

Personal Safety.—Never close a circuit through the body. An accidental contact may be made through the feet, hands, knees, or other part of body in some peculiar and unexpected manner. For example, men have been killed because they were sitting on a conducting body.

Rubber gloves or rubber shoes, or both, should be used in handling circuits over 500 volts. The safest plan is not to touch any conductor while the current is on, and it should be remembered that the current may be present when not expected, due to an accidental contact with some other wire or a change of connections. Tools with insulated handles or a dry stick of wood should be used instead of the bare hand.

The rule to use *only one hand* when handling dangerous electrical conductors or apparatus, is a very good one, because it avoids the chance, which is very great, of making contacts with both hands and getting the full current right through the body. This rule is often made still more definite by saying, "Keep one hand in the pocket" in order to make sure not to use it. The above precautions are often totally disregarded, particularly by those who have become careless by familiarity with dangerous currents. The result of this has been that *almost all the persons accidentally killed by electricity have been experienced electric linemen or station men.*

ELECTRICAL EXECUTION AT ABATTOIRS.

The Aberdeen abattoir is about to be lighted by electricity. In the event of the use in this direction of an alternating-current dynamo, a trial will be made of its capabilities for slaughtering cattle. It is anticipated that this application may become general if experience should prove that it has no detrimental effect upon the quality of the meat.

THE CAPACITY NECESSARY TO NEUTRALIZE A GIVEN SELF-INDUCTION.

BY

Norman Whichello.

MR. SWINBURNE'S recent paper, "The Probable Future of Condensers in Electric Lighting," having drawn attention to the use of condensers for supplying large "idle currents," or what I may term large "idle volts," instead of allowing the dynamo to do it, it has occurred to me that it might be well to show how to calculate the magnitude of the capacity required.

If we have a magnetic circuit to be energized we may do either of two things; (*a*), wind the magnetizing coils as for a continuous current of the same voltage as the alternator, and then place in series with them a condenser of such a capacity as to supply the P. D. necessary to drive the required current against the large impedance of the coil, Fig. 2; or (*b*), we may use a few turns of thick wire and shunt them by a condenser of such a capacity that the large idle current passing through the coils is supplied by the condenser instead of the dynamo.

It only remains to calculate the value of the capacity.

Case (*a*)

Let L = the self-induction (henrys).
r = the resistance (ohms).
k = the capacity (farads).

Let $C = C_0 \sin pt$ be the required current ($p = 2\pi$ times the frequency). Now if at any moment V be the P. D. between the coatings of the condenser and Q the charge on either coating, then $k = \frac{Q}{V}$.

$$\therefore \frac{dV}{dt} = \frac{1}{k} \cdot \frac{dQ}{dt} = \frac{1}{k} \cdot C$$

$$\therefore V = \frac{1}{k}\int C\,dt = \frac{1}{k}\,C_0\int \sin pt\,dt = -\frac{1}{kp}C_0 \cos pt.$$

And the P. D. required to drive the current against the self-induction is $L\frac{dc}{dt} = L \cdot \frac{d}{dt}\,C_0 \sin pt = L\,C_0 \cos pt.$ And against the resistance simply $r \cdot C_0 \cdot \sin pt.$ Hence the whole P. D. required is

$$V = C_0\left\{r \sin pt + \left(Lp - \frac{1}{kp}\right)\cos pt\right\},$$

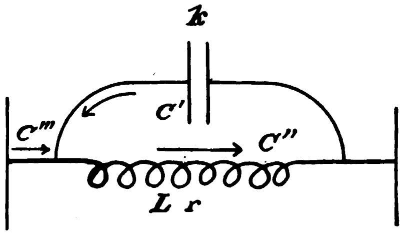

FIG. 1.

and this, by a well-known transformation, is

$$V = C_0\sqrt{r^2 + \left(Lp - \frac{1}{kp}\right)^2}\,\sin(pt + \varphi),$$

where φ is a lag angle; $\varphi = \tan^{-1}\left(\frac{Lp - \frac{1}{kp}}{r}\right)$.

Now if $Lp = \frac{1}{kp}$ *i. e.*, if $k = \frac{1}{Lp^2}$ the second term under the root vanishes and we have simply, $V = C_0 \cdot r \cdot \sin pt$

the same current which we should have if there were no self-induction and no capacity, in fact a current of the same effective value as on a continuous circuit of the same effective pressure.

The value which neutralizes the self-induction is then $k = \frac{1}{L p^2}$; curiously enough we shall find the same value for k in the parallel arrangement.

Notice that by increasing the frequency we can rapidly decrease k.

Case (b)

Let the volts on the mains be $V = V_0 \sin pt$, and use the same symbols as before; $k = \frac{Q}{V}$.

$$\therefore k \frac{dV}{dt} = \frac{dQ}{dt} = C'$$

$\therefore C' = k \frac{dV}{dt} = k \frac{d}{dt} (V_0 \sin pt) = V_0 k p \cos pt$, and the current through the inductive circuit is of course

$$C'' = \frac{V_0}{\sqrt{r^2 + L^2 p^2}} \sin (pt - \theta);$$

$$\theta = \tan^{-1} \frac{L p}{r}.$$

The current C' passes round the inductive coil and adds itself to the dynamo current C''', Fig. 1. Consider its sign carefully. Suppose for the moment that r were negligible; then both currents would be in quadrature with the E. M. F. on the mains, C' in front of the E. M. F., C'' behind it; consequently they would reach maxima simultaneously, C' flowing towards one main as shown by the arrow C'' away from that main as shown by its arrow; but C' passes through the inductive coil, and, as regards this local circuit round which C' flows, *these directions are the same.*

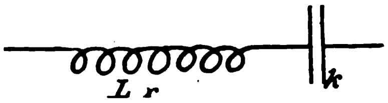

FIG. 2.

Hence we can find the value of C'' by changing the sign of C' and adding it to C'''.

$\therefore C''' - C' = C''$, hence C''' the dynamo current is

$$C''' = C'' + C'$$

$$= V_0 \left\{ \frac{1}{\sqrt{r^2 + L^2 p^2}} \sin (pt - \theta) + k p \cos pt \right\} \qquad (1)$$

And this may be reduced to

$$C''' = V_0 \sqrt{\frac{1 - 2 k L p^2}{r^2 + L^2 p^2} + k^2 p^2} \sin (pt + \psi) \qquad (2)$$

where ψ is a lag angle.

Now if $k = \frac{1}{L p^2}$ and $r = 0$, we have $C''' = 0$, so that the condenser would now be supplying the whole current (as we could have seen more easily in this special case, *i. e.*, when $r = 0$).

If $k = \frac{1}{L p^2}$ but r is not 0, then

$$C''' = V_0 \frac{r}{L p \sqrt{r^2 + L^2 p^2}} \sin (pt + \psi) \qquad (3)$$

But this is not quite the best value for k as we can see by differentiating the expression under the root in (2). If we do this we find that $k = \frac{L}{r^2 + L^2 p^2}$ makes C''' a minimum.

If $k = \frac{L}{r^2 + L^2 p^2}$

$$C''' = V_0 \frac{r}{r^2 + L^2 p^2} \sin (pt + \psi)$$

The amplitude of this current $V_0 \frac{r}{r^2 + L^2 p^2}$ is clearly somewhat smaller than that of the other $V_0 \frac{r}{L p \sqrt{r^2 + L^2 p^2}}$ and it is attained by the use of a smaller capacity. The difference however will be very slight in practice as $L p$ will be very much larger than r when iron is being magnetized.

Hence we may say that whether the condenser be arranged in series or in parallel with the inductance it should be equal to $\frac{1}{L p^2}$.

It might be well to point out that in consequence of alternators not giving true sign waves in practice and also in consequence of the fact that L is not constant when there is iron to be magnetized it will not be possible in practice to realize the above conclusions exactly.

That the capacities required are not usually inconveniently great the example below will show.

Let it be required to neutralize a self-induction of 5 henrys, the periodicity being 100 ~ per second.

$$\therefore L = 5 ; p = 2 \pi 100$$

$$k = \frac{1}{L p^2} = \frac{1}{5 \,.\, 4 \,.\, 10^4 \,.\, \pi^2} \text{ farads,}$$

$$= \frac{1}{2.10^6} \text{ farads (about)}$$

$$= 0.5 \text{ microfarad.}$$

THE DESIGNING OF DYNAMO ELECTRIC MACHINES.[1]

OSBORN P. LOOMIS.

DYNAMOS may be considered in two classes, namely, those used for supplying a variable current at a constant or nearly uniform pressure (such as those used in incandescent lighting) and those used in supplying a constant current at variable pressures depending on the resistance to be overcome in the external circuit. It might appear to some that the rules of design of a dynamo of one class ought to apply to the other, except in the matter of winding the frames, and it was at one time thought so even among electricians; but as investigation progressed it was found that not only were the requirements different, but different methods of designing were necessary to secure practical results.

The foundation stone of the dynamo-electric machine is magnetism, and in the incandescent machine this is particularly so. The days of slim and skinny dynamos for this work have gone by. The field magnets should be large and as short as compatible with the necessary wire to be wound upon them. The same holds true with regard to the pole-pieces, and I think that it is generally conceded among electricians that drum armatures are superior to the ring type for this class of work, except in the case of multipolar dynamos, which embody but another way of reducing the magnetic resistance of the core of the armature by multiplying the number of paths or circuits. With these conditions there is less distortion of the field magnetism upon changes of load put upon the armature.

Contrasted with machines for incandescent lighting, the design of a dynamo for running arc lights might be quite reversed. The frame should be quite light, and the pole-pieces should be thinned down, and in this case a ring armature is much to be preferred on account of electrical and magnetic reasons which will appear later.

The winding of dynamos is now generally divided into three classes or systems, as follows: 1. Series winding, in which all the current generated by the armature passes around the field magnets to the external circuit. 2. Shunt winding, in which only a part of the current passes around the field. 3. A mixture of the preceding called compound winding. This is a shunt wound dynamo, with the exception that all of the generated current passes around the field magnets a few times only, and assists the shunt magnetism for a regulative purpose.

This type is especially useful in generators for motor and incandescent work, and the object is to produce a constant pressure, and in some cases, to slightly increase it with increase of load to compensate for loss of potential in the line circuit to the point of consumption. These changes are instantly and automatically made in the dynamo itself without the aid of external appliances which are necessary in the use of a simple shunt wound dynamo. I might remark that in the early practice of compounding dynamos, this extra magnetic effect in some cases nearly equaled the shunt effect on acconnt of the high resistance of the armatures then built; but in recent dynamos this extra effect is comparatively small owing to the armatures being wound with few turns of wire.

---

[1] A paper read before the Electrical Section of the Brooklyn Institute.

An additional advantage of the compounding is the strengthening of the field at the same instant the load comes on the armature, because at that time there is a tendency to distortion of the field magnetism, and still better effects result by placing the series or compound coils on the pole-pieces, or, as is sometimes done, over the whole armature. It might be argued that putting them anywhere on the magnetic circuit of the machine would do as well, as the magnetism must keep to the circuit; but in the large pole-pieces such as are commonly used, I think that the magnetic lines would be more easily pushed to one side if there were no winding on the pole-pieces. I will state that in my experience copper strip has given excellent results, the resistance being very low and the winding very compact.

What is known as series winding is principally used in dynamos for arc lighting to which it is admirably adapted. This class of generators has, until recently, been much misunderstood. It used to be thought that by shifting the brushes they were moved to points of higher or lower potential on the commutator, which is undoubtedly true, but is not all the truth; for, as the brushes are shifted, the magnetic or polar line is also shifted and this influences the field to a remarkable extent owing to the great number of turns on the armature which are necessary to produce the requisite pressure for this class of work. Together with this a comparatively weak field magnetism is used but is held above saturation by many wire turns in the field bobbins. In this condition of things the armature might be roughly termed a valve which allows more magnetism to pass through itself when the current is lessened (that is, by adding arc lamps) and tending to shut it off when the current is increased, as when lamps are cut out.

These effects are due, principally, to the peculiar construction of this armature running in a nearly constant field. These principles are taken advantage of by Mr. Stanley in his constant current alternating dynamo which automatically produces a uniform current from the capacity of the machine down to a short circuit. Of course, in a continuous current machine these actions are supplemented by an automatic regulator which shifts the brushes, and, as above stated, changes the polar line of the armature which intensifies these effects.

Attention is called to the stability of current in these dynamos. An arc light is a very unsteady resistance and it will be seen that if the field were responsive to these changes we would have anything but a constant current. This explains why it is necessary to put so little iron in the field magnets. Under these conditions they are above the saturation point and changes of the current in the field coils produce little change in magnetism. If this were not done there would be a periodic rise and fall of current and E. M. F.

In dynamos that produce a variable current with a constant or nearly uniform pressure at their terminals nearly the opposite course in design must be followed. The fields should be large and thick or be made multipolar, which is another and in many respects better, way of securing the same result. The magnetic effect of the armature should be made small by winding few turns of wire upon it. Electricians have been slowly but surely tending towards this point and, in proportion, better results have been realized. Another advantage secured in this design is the slight change in the non-sparking points on the commutator. This is due, of course, to a very weak armature running in a strong field, magnetically speaking.

Another extremely important point is that of diminishing the air gap by winding the armature with only one layer of wire. This reduces the resistance of the magnetic circut and renders it less liable to distortion under the varying currents delivered by the armature. If it were possible to find a suitable magnetizable substance which was at the same time a good conductor of electricity (say like copper) I think we could build what might be termed a commercially perfect dynamo (that is of this class); for with no air gap we could keep the polar line of the field perfectly steady. Consequently, what is termed the neutral or non-sparking points on the commutator would never shift and that trouble, known as sparking, over which electricians have heaved so many sighs, would be forever at an end. As this dream is certainly not realized at the present time, the next best thing we can do is to approach it as nearly as possible by reducing this air gap to its lowest limit. It is better to increase the circumference of the armature core in order to get the surface room than to put on the necessary turns in two layers, for the increased iron in the core is to the air space as 1 is to 20,000. Added to this is the advantage of a higher peripherial velocity of the armature wires.

If it is desired to secure extra fine results in special requirements it would be profitable to allow the surface of the poles to come down close to the conducting wire and bore slightly larger for the binding bands. It might not appear that the results would warrant the trouble, but it can easily be demonstrated.

In regard to armature cores I notice it has been the practice with some builders to carefully insulate the sheet iron discs from the shaft by a non-conducting sleeve. This certainly increases the magnetic resistance of the armature and in my experience I have found it wholly unnecessary. By slipping the discs upon the armature shaft directly I have not been able to discover any heating. It certainly saves trouble and at least ought to produce the same results.

Of late there has been some tendency to the use of laminated cores for field magnets. Apart from the better quality of iron, I cannot see any advantage in this practice, for the following reason: All lamination is used to break up circulating currents in the metal subject to magnetic changes, of which an armature is an excellent example; but with the exception of a dynamo using a toothed armature I think that it is generally understood that no magnetic changes occur in the field of a dynamo, or at least not with the frequency necessary for this precaution. In the case of a toothed armature I think a laminated pole-piece would be sufficient for all practical purposes, of course, referring to continuous current dynamos.

In practice I find good results by making the width of the pole piece equal to the diameter of the core. The following data of a machine embodying the principles just enumerated may be of interest.

Data of 16 Kilowatt Dynamo.

110 volts; 150 amperes; 1,400 revolutions.

Resistance of Armature	.022 ohm.
" " Series Coil	.005 "
" " Shunt Fields	20.00 ohms.
Area of cross section of each core	48.6 sq. in.
Area of cross section of pole-piece	107.5 sq. in.

60 turns on armature in one layer.
24 " " Series Coils.
4,088 " " Shunt Fields.

Cross section of wire on armature	25,998 sq. mils.
" " " Copper strip on series	138,000 " "
" " " Wire on shunt fields	5,128 " "

There are some few practical points in regard to commutators and brushes worth mentioning. A brush should bear with a firm elastic pressure on the surface of the commutator. If the spring is not stiff enough, any little unevenness on the commutator will cause the brush to jump from the surface and then trouble commences and grows worse instead of better. By using a firm spring the brush will be held to the surface regardless of slight projections. Again, the brush-holders should be free to slide laterally on the studs to allow the brushes to be placed on the surface of the commutator so as to break joints, thus keeping it free from ridges.

When the commutator pits out at one segment repeatedly a defective joint will generally be found at the junction of the wires and bar. The explanation is that as the brush leaves a good connection and strikes a poorer one a spark is formed repeatedly and gradually eats it away.

It might be thought that the electrical part of the dynamo was all that was worth talking about, but I might mention a little incident. While conversing with a mechanical engineer of considerable experience he remarked that electricians had to learn mechanical experience all over again in the matter of journals, which had not been made long enough in the past. They should be made large, not because a larger bearing in itself runs cooler, but because large shafts do not spring out of line while running.

Turning toward the subject of lubrication there are several forms of self oiling journals in use and they generally give satisfaction, being automatic and much cleaner in their operation. A form recently designed consists of a woven chain ribbon running over, or carried by, a serrated surface on the shaft. I think that this may have some advantages over the ring, as it seems to gather up more oil. There are many that think the old oil cups are good enough but I am sure a little experience with a self oiling machine would secure their preference.

SUBSIDY FOR A CABLE TO JAPAN.

It is officially announced at Ottawa, Can. that the Canadian Pacific Railway has received positive assurances that the Imperial Government will grant a subsidy toward the construction of a new submarine cable between British Columbia and Japan. President Shaughnessy of the railroad, who has just arrived from Yokohama, says that arrangements have been made with the Mikado's Government for the use of land lines in Japan. Efforts are now being made among English capitalists to raise the money and float a company to undertake the construction and operation of the proposed cable in conjunction with the Commercial Cable and the Canadian Pacific route, as already chosen. This route presents very few obstacles and is certainly much better than the Southern Pacific route.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, MARCH 16, 1892. NO. 202.

There is nothing superfluous, or deficient, or accidental, or indifferent in Nature.—Faraday.

SIEMENS & HALSKE IN AMERICA.

ALLUSION has already been made more than once in THE ELECTRICAL ENGINEER to the reported intention of Siemens & Halske, the great electrical manufacturers of Europe, to establish a branch or semi-independent factory in this country—thus taking a leaf out of the book of the Western Electric Co., who have rooted themselves firmly in Europe, and whose success there is an old story. It is now stated that Siemens & Halske will build their American works at once, taking Chicago as a location, and that they will impress the public with their presence and importance by making a very fine display at the World's Fair next year.

In some quarters there is a disposition to be incredulous with regard to this rumored new departure, but we have good reason to assert that large plans will soon be carried into effect. It might, perhaps, be thought that the plan is a counterclap to the movements recently made by the Thomson-Houston Company in Germany. There, as we mentioned about a month ago, the Union Electric Company has just been organized in Berlin, consisting of Loewe & Co., Thyssen & Co., Mulheim-on-the-Rhine, and the Thomson-Houston International Electric Company of Boston. The new concern has acquired all the patent rights of the Thomson-Houston International Electric Company for Germany, Austria and Northern and Eastern Europe. The company, it is said, does not intend to erect its own factories, but will have its entire manufacturing done by Loewe & Co. The capital stock of the new company is 1,500,000 marks, equally distributed between the three contracting parties. The company will devote special attention to the introduction of Thomson-Houston apparatus, both for lighting and power purposes. Now, it might be argued that the proposition of Siemens & Halske to "carry the war" into America is intended to check or offset this invasion in heavier force of their own territory; but such seems to us a narrow view of the situation.

Siemens & Halske will not be the first manufacturers to migrate from Europe to this country nor will they be the last. As we said a few weeks ago, the fact that even two such strong concerns as the Edison and Thomson-Houston companies have joined hands does not by any means prove that the field is closed up for others who would exploit the numerous opportunities of electrical work. While the new American combination controls many extremely valuable patents, some of them exclusive, it is far from monopolizing all the electrical inventions of the age in light, heat and power; and with the increasing activity in every department, the likelihood of such a concentration grows less possible every month, especially as the lapse of time must throw open to the public that which now enjoys rightly the protection of the law. There comes a point, too, in every great industry, even the simplest, at which it ceases to be desirable or feasible to invest any body of men with more and more power, simply because executive ability is limited by harsh conditions of time, strength, and distance. With respect to the Siemens & Halske Company, it may be pointed out that they are genuine pioneers in light and power, and that they thus have also a number of formidable patents, as well as a fund of experience that would be hard to beat.

It is understood, we have said, that the Siemens & Halske works will be established at Chicago, though there is a possibility that the concern may build a town of its own, if it intends to employ the 4,000 men with whom rumor credits it. We can only say that the American electrical public will be glad to see this enterprise started, and that while no one expects to learn much from its European methods, the indirect good to the electrical industries of the country by this accession of skill and capital must be enormous.

ELECTRICITY FOR MASSACHUSETTS STEAM ROADS.

THE late James T. Furber, general manager of the Boston and Maine Railroad system, was a believer in the near substitution of electricity for steam on many of the shorter railroads of New England, and he appears to have found other railway men who agreed with him, notably President Choate, of the Old Colony Road. Be this as it may, the ripening of conviction is seen in the fact that the Railroad Committee of the Massachusetts Legislature has unanimously reported a bill to permit change from the one motive power to the other. The bill provides that "Railroad Corporations which are subject to the provisions of chapter 112 of the Public Statutes and amendments thereto are hereby authorized to operate their railroads by electricity." The chapter referred to is the railroad law of the it is not surprising to see her prompt to try a motive State. It will be remembered that Massachusetts began very early in the matter of adopting steam locomotion, and power that has already given so much satisfaction in the heaviest street railway work. Meantime, the Pennsylvania Railroad Company is beginning its Newark road across the Jersey marshes, and Mr. Villard is studying out the problem for Chicago. May we not hope that the New York Central will soon give us such a service for the Tunnel, from 125th street to the 42d street depot?

THE LAW OF DIELECTRIC HYSTERESIS.

The investigations carried on by Mr. Charles P. Steinmetz on the nature of hysteresis in iron and other magnetic metals have already resulted in the enunciation of a most important law, which cannot fail to be of the greatest service to the constructor of dynamo-electric machinery and electro-magnetic apparatus in general. But those who have followed the course of events, especially in modern alternate current work, cannot fail to have recognized the increasing importance and application of the condenser as an auxiliary apparatus employed to obtain the necessary phase difference. Mr. Steinmetz has now enunciated the corresponding law for the electrostatic cycles in dielectrics, and it is interesting to note that while in the case of iron the magnetic hysteresis varies as the 1.6th power of the magnetization, the electrostatic hysteresis follows the simple law of squares. Exact determinations of electrostatic phenomena are far more scarce than were those of magnetic hysteresis before the publication of Mr. Steinmetz's recent paper, and probably because the difficulties accompanying such determination are greater than in the case of magnetic hysteresis. That electrostatic hysteresis will have to be taken into account in large modern power alternate current transmissions is evident from the results obtained at Frankfort. Where the capacity of the lines is necessarily large, a very large charging current is present and the loss of energy by dielectric hysteresis may have a large influence on the efficiency of transmission. The direct bearing of the law enunciated by Mr. Steinmetz in such cases must be at once apparent, and it is to be hoped that he will continue his researches in this branch.

COST OF LONG-DISTANCE TRANSMISSION.

Much has been said and written recently on long-distance power transmission by electricity, but as President Huntley pointed out in his address before the National Electric Light Association, at Buffalo, the one question above all which cannot be lost sight of is, Will it pay? For, however promising schemes of this sort may appear, and however willing and able the engineer may be to carry out the work, the investor never loses sight of the fact that a fair return for the capital outlay must be reasonably assured. We also showed in this column in our last issue how easily one might be misled into the belief that a water-power, apparently abundant, might be transmitted to a distance, when a close analysis of the conditions involved would soon bring out the contrary fact. In discussing this subject in a recent address before the Chicago Electric Club, Dr. Louis Bell, after describing the various methods which the electrical engineer has available for this work in the different kinds of apparatus and types of motors, lays special stress upon the cost of such transmission. Taking as an example, to begin with, a case of direct current supply, he places the cost of generators at $30 per horse power. To this must be added, of course, the cost both of the copper wire and the pole line, and it is the latter which is too often lost sight of in the calculation. As Dr. Bell shows, the cost of the poles would vary very little, if any, with the potential employed, and hence with the amount of copper required; and, allowing 45 poles to the mile, the poles alone would cost $250 a mile, so that for long-distances the total expenditure would run up quite rapidly. If a motor generator be employed, there is the cost of three machines, costing, probably, $90 per horse power, initially. This would allow the use of high potentials and of a considerable saving in copper, and possibly, of somewhat lighter poles. The gain to be derived by the use of step-up transformers Dr. Bell showed depends very much upon the distance to be traversed, for it may happen that the cost of copper per kilowatt transmitted is less than $30, the cost of the transformers, and the distance to which one would be able to go before it would pay to step up, would thus be a considerable number of miles. Dr. Bell believes, in substance, that up to distances of 25 or 30 miles any one of the well-known methods now proposed are fitted to answer the purpose, but that to handle extremely long-distance work, still requires time and study.

ECONOMY IN ARC LIGHT WIRING.

The difficulties experienced in incandescent lighting at long distances, owing to the large amount of copper required, early led to the devising of the three-wire and other systems for effecting economy in this respect, and later on, to the alternating system. But while all these improvements have been going on in incandescent lighting work, few persons seem to have bestowed any attention on arc light circuits, which involve a by no means small outlay of capital, especially in our larger cities. Those engaged in the distribution of arc lighting for commercial and street lighting purposes will, therefore, be interested in the method described elsewhere by Mr. S. H. Sharpsteen for effecting a reduction in the amount of copper used, as well as in the number of circuits running out from a station. The method employed by Mr. Sharpsteen is quite analogous to that used at the Amoskeag Mills, at Manchester, N. H., as far back as 1881–82, and which has been cited as an assumable anticipation of the Edison three-wire system. In that case, however, the object sought for was to avoid a total extinguishing of the light in case one of the circuits broke down, while Mr. Sharpsteen, in addition, employs the method to effect quite a different object.

GOVERNMENT TELEGRAPHS AND TELEPHONES.

It would perhaps have been well if some of the active and high spirited business men of this country who are advocating control by the Government of the telegraphs and telephones could have been in Berlin during the recent riots. They would have found that the moment they made the slightest allusion to the riots, while using the telephone, the circuit was cut off, no matter how innocent the remark or how important the business under discussion. If American merchants and professional men want this kind of espionage and arbitrary interference, they deserve no better treatment. Moreover, the control of the telegraph lines was not less severe and rigid.

ON THE LAW OF HYSTERESIS.—VI.

BY CHARLES PROTEUS STEINMETZ.

1. The hardened steel curve, of high coercive force, has the bend or "knee" on the *negative* side, so that for zero M. M. F. the "remanent" magnetism is still in the saturation part of the curve —that is, in stable equilibrium; therefore permanently magnetizable.

2. The soft iron curve, with the bend on the *positive* side, so that for zero M. M. F. the "remanent" magnetism, though still very high, is already below the range of saturation, on the branch of unstable equilibrium. Therefore the remanent magnetism is very unstable and easily destroyed, the more as the coercitive force is very small.

3. The cast-iron curve, which has no marked knee at all, but a steady curvature of low remanent magnetization, but with regard to coercitive force ranging between 1 and 2.

The curve of the magnetic iron ore shows all the characteristics of a cast-iron curve.

Having derived, now, a larger number of values of the hysteretic coefficient η for different kinds of iron and other material, we shall put them together for comparison in Table XII.

For convenience, in the accompanying table are given the values W of consumption of energy in watts per cubic inch, for 100 complete periods (magnetic cycles) per second, and for the magnetization of H lines of force per square inch, giving as coefficient of hysteresis the value $\gamma = 8.3 \times 10^{-6}\ \eta$.

TABLE XII.

$$W = \gamma\ H^{1.6}$$

W in watts per cubic inch and 100 complete periods per second.

H in lines of magnetic force per square inch.

	γ	$H =$	10,000	20,000	30,000	40,000	50,000	60,000	70,000	80,000	90,000	100,000	110,000	120,000	150,000

H — 25,0000 : alternate current transformer, American style (high frequency).

H — 35,000 ; " " " European " low "

Only the values smaller than .25 W, can be of practical use; in those larger than 10 the iron gets at least red hot if in larger quantities.

In the foregoing I have given a number of experimental values of the consumption of energy by hysteresis and believe to have shown that this consumption of energy can fairly well be expressed by the empirical formula, $H = \eta\ B^x$ where the exponent x is equal, or at least very nearly, to 1.6, and the coefficient η a constant of the material, which ranges from .002 to .025 and more, and may possibly have a slight dependence upon the *velocity* wherewith the magnetic cycle is performed, as the second set of alternate-current readings seems to indicate.

In the following Table XIII, I give the values of the hysteretic resistance η for some iron samples, subjected to a magnetic cycle between $F = + 190$ and $- 190$ ampere turns per centimetre, calculated from Hopkinson's tests[1] by the assumption of the law of hysteresis: η denotes the coefficient hysteresis; B the maximum magnetization in lines of magnetic force per square centimetre; R the remanent magnetization in lines of magnetic force per square centimetre.

These values of the hysteretic coefficient vary from .002 up to .082, 41 times the first value.

But especially noteworthy is the fact that η depends much less upon the chemical constitution of the iron sample, than upon its physical condition, *annealing decreasing*, and *hardening increasing* the hysteresis very considerably. So far as the chemical constitution is concerned, the purer the iron the lower is its hysteresis, while any kind of foreign matter increases the hysteresis. Especially manganese increases the hysteretic loss enormously, much less tungsten and chromium, least silicon and carbon. Connected with the increase of hysteresis is always a decrease in susceptibility.

I wish to add a few remarks on two alleged phenomena connected with hysteresis, which have been talked about considerably, without yet being made clear; the decrease of hysteresis for open magnetic circuit, and the decrease of hysteresis of a transformer with increasing load. With regard to the first, as shown, actual tests do not show a smaller value of hysteresis for open than for closed magnetic circuit. And it cannot be understood how that could be. For consider an iron molecule of the magnetic circuit exposed to the harmonically varying M. M. F. and performing a magnetic cycle. Evidently it can make no difference for this iron molecule, whether some trillion molecules further away, the magnetic circuit ends in air, or is closed entirely in iron, supposed that the M. M. F. and the magnetism, and therefore also the magnetic reluctance, are the same in both cases. Neither can it make any difference whether the M. M. F. is caused only by one sine-wave of electric current, or is the resultant of several M. M.

---

[1] From "Kalender für Electrotechniker," by Uppenborn, Berlin, Germany.

F.'s, as in the loaded transformer. It is the same as with the electric current, where the energy converted into heat in each molecule of the conductor does not depend either, whether the material of the conductor on some other point changes, or whether one or more E. M. F.'s are acting upon the circuit. Hence, until absolutely exact and unquestioned determinations of the hysteretic loss for fully loaded transformers are at hand, the assumption of a decrease of hysteresis with increasing load must be rejected.[1]

That an apparent decrease with increasing load has been observed several times may be conceded, for besides the exceedingly great liability to errors in these tests, where the hysteretic loss comes out as the small difference of two large values, primary energy and secondary energy, and therefore is very much affected by the slightest error in any one of the components, it must be understood that the main possible errors in the determinations on fully loaded transformers all point this way. Neglect of secondary self-induction, decrease of magnetization with increasing load, slowing down of the dynamo-alternator, etc., all cause an apparent decrease in the hysteretic loss for increasing load. At least in one set of tests, those made by Prof. Ryan, at Cornell University, on a small Westinghouse converter, I was able to show in my "Elementary Geometrical Theory of the Alternate Current Transformer"[2] that the observed decrease of the hysteretic loss disappears by reducing the different readings to the same magnetization and the same frequency.

That an electromagnet without keeper loses its magnetism quicker than a magnet with keeper, or a closed magnetized iron ring, is a phenomenon, which has nothing whatever to do with this loss of energy by hysteresis, but is merely due to the demagnetizing force of the remanent magnetism. For the remanent magnetism in an open magnetic circuit causes between its poles a certain difference of magnetic potential, which in the moment of breaking the electric circuit acts as demagnetizing M. M. F., and if the coercitive force is small, as in wrought iron or annealed steel, almost entirely destroys the remanent magnetism, while in an iron of large coercitive force it affects the permanent magnetism very little. In the closed magnetic circuit the remanent magnetism causes none or very little difference of magnetic potential, and therefore no destruction of the remanent magnetism by its own demagnetizing M. M. F. takes place. But with the hysteretic loss of energy this phenomenon has nothing to do.

To combine the results, what I believed to have proved is that loss of energy in iron caused by reversals of magnetism can be expressed by the analytical formula: $H = \eta B^{1.6} + \varepsilon N B^2$ where η is the coefficient of hysteresis, ε the coefficient of eddy currents, N the frequency of the alternations of magnetism, $\eta B^{1.6}$ the loss of energy by hysteresis proper, or by *molecular friction*, and $\varepsilon N. B^2$ the loss of energy by eddy currents, per magnetic cycle and per cm.[3] proportional to the frequency N.

TABLE XIV.

For convenience, I give in Table XIV., the values of the 1.6th power of the numbers, from 500 to 50,000 with the increase of $B^{1.6}$ for 100 lines of magnetic force.

Having had time in the last few days to consider more deeply the relations of this Law of Hysteresis to Ewing's theory of magnetism, I came to the conclusion that this Law of Hysteresis agrees very nicely with Ewing's theory, giving just the phenomena that this theory leads us to expect.

According to Ewing's theory, for very low M. M. F.'s forces too small to affect the chains of molecular magnets, which exist in the magnetizable body when not under magnetic strain, the magnetic cycle should be almost reversible, that is hysteresis very small or almost nil.

For medium M. M. F.'s, that is, M. M. F.'s large enough to break up the chains of molecular magnets, the magnetic cycle should be expected to become markedly irreversible, and the hysteresis, as function of the M. M. F. must rapidly increase.

For high M. M. F.'s, where the chains of molecular magnets are already for the most part broken, the hysteretic loss, as function of the M. M. F. should increase more and more slowly.

This is exactly the case if the hysteresis follows the law of the 1.6th power of the magnetization.

This is not directly plain, because the law of 1.6th power gives the dependence of the hysteresis upon the *magnetization* while, to compare it with Ewing's theory, we have to produce the hysteresis as function of the M. M. F.

This is done in the diagram given in Fig. 5.

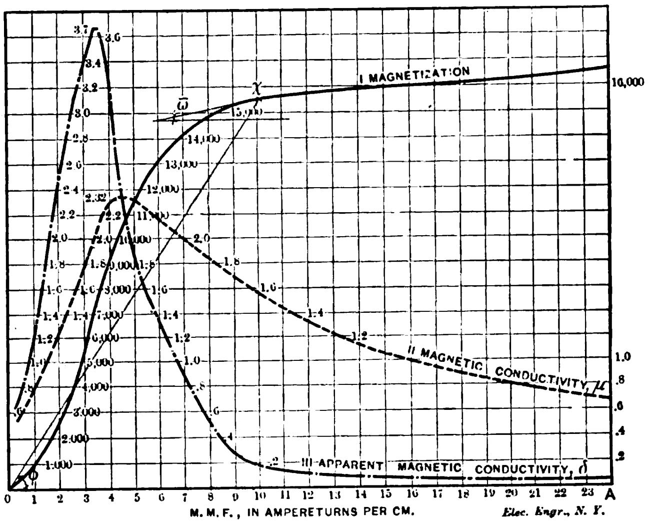

FIG. 5.

Here the *dotted curve* gives the magnetization B, in lines of magnetic force per $cm.^2$ as function of the M. M. F. F as abscissæ

In the *drawn curve* are given the losses by hysteresis, in ergs per cycle and $cm.^3$, calculated by the law of hysteresis: $H = .003507\ B^{1.6}$ but plotted not as function of the magnetization B, but as function of the M. M. F. F also: $H = f(F)$.

As seen from the plotted curve of hysteresis,[1] the hysteretic loss for low M. M. F.'s, $F = 0 \sim 1$, is very small and almost nil, then rises very rapidly for medium M. M. F.'s: $F = 2 \sim 5$, and then, for high M. M. F.'s, rises more and more slowly, just as Ewing's theory leads us to expect.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 8, 1892.

Alarms and Signals:—

Fire-Alarm and Telephone Apparatus, E. H. Amet, 470,231. Filed July 26, 1890.

The combination of a telephone system with an automatic fire-alarm.

Automatic Heat-Signaling Device, W. G. Day, 470,478. Filed March 18, 1891.

An automatic call box which will serve as a messenger call, a thermostat or a hand-operated fire signal.

Conductors, Conduits and Insulators:—

Conduit for Electric Wires, C. A. Freeman, 470,237. Filed Sept. 25, 1891.

Consists of a series of tubular sectional tiles fitted together by means of tongues and grooves which lock the sections against lateral and vertical displacement.

Underground Cables for Electric Cables, C. A. W. Hultman, 470,329. Filed June 9, 1891.

An underground conduit strengthened by means of metallic bars held in exterior longitudinal grooves and secured by cement.

Insulator for Overhead Electric Railways, H. D. Winton, 476,356. Filed Oct. 22, 1891.

Consists of an insulated body portion having at its extremities projecting studs to receive interchangeable attaching pieces for clamping the trolley wire and securing the insulator to the supports.

Insulator for Trolley Wires, W. S. Andrews and H. P. Ball, 470,417. Filed Oct. 1, 1891.

Insulator body composed of wood having a spun metal cover.

Dynamos and Motors:—

Electric Motor or Dynamo-Electric Machine, H. H. Hosford, 470,194. Filed June 4, 1891.

Employs a fixed commutator composed of bars having an angular relation to the brushes and their holders.

Electric Motor or Generator, R. Kennedy, 470,199. Filed Sept. 24, 1890.

Employs a field magnet having two independent windings and two independent synchronously rotating commutators, connected respectively with the windings in combination with the generator transmitting to each of these commutators an independent alternating current of like periodicity but of dissimilar phase.

---

[1] The latest of Ewing prove that, in a fully-loaded transformer the loss by hysteresis is *not* smaller than for open secondary circuit.

[2] THE ELECTRICAL ENGINEER," December, 1891.

[1] This curve of hysteresis corresponds to a set of determinations, not contained in the paper, because made afterwards. I chose just this particular set of tests, because it covered a larger range of magnetizations than any one contained in the paper.

Connection for Armature Conductors, G. Stephens, 470,217. Filed Nov. 18, 1891.

Consists of means for attaching commutator strip to the segments without the use of solder while insuring permanent and reliable connection.

Electric Generator, C. J. Van Depoele, 470,521. Filed May 18, 1887.

Relates to improvements in systems of generating electric currents of constant potential.

Galvanic and Thermo-Electric Batteries :—

Electric Battery, V. Riatti, 470,260. Filed June 9, 1891.

Consists of a vessel composed of a bad conductor of heat and electricity charged with liquid capable of conducting electricity and having an electrical conductor at the bottom and a heating and conducting body at the top of the liquid.

Galvanic Battery, J. H. Davis, 470,552. Filed April 24, 1891.

A light, flexible battery jar in which the liquid is kept in continuous circulation through the chemical excitant and in contact with the electrodes of the battery.

Heating :—

Electrically Heated Oven, J. V. Capek, 470,418. Filed March 24, 1891.

Electric Oven, J. V. Capek, 470,419. Filed Aug. 14, 1891.

Lamps and Appurtenances :—

Regulating Socket or Holder for Incandescent Electric Lamps, E. E. Ries and W. S. Horry, 470,402. Filed May 5, 1891.

A socket for alternating current incandescent lamps, by means of which the intensity of the light may be varied by setting up a variable counter-electromotive force opposing the flow of current to the lamp.

Incandescent Electric Lamp, A. C. Carey, 470,471. Filed Aug. 3, 1891.

Claim :

In an electric light lamp leading-in or circuit wires, an incandescent filament, and a joint therefor composed of a double tube in which the ends of the filament and leading-in or circuit wires are secured.

Electric Search Light, R. S. Dobbie, 470,688. Filed Apr. 16, 1891.

Consists of improved means of mounting the lamp in the projector and for controlling its several moving parts.

Measurement :—

Movable Coil for Electrical Measuring Instruments, E. Weston, 470,340. Filed Mar. 11, 1891.

Electrical Measuring Instrument, E. Weston, 470,341. Filed June 4, 1891.

An electrical measuring instrument employing a movable and a fixed coil of wire, a mechanical dash pot to check the movement of the movable coil and means of converting the axial movement of such coil into rotary movement of an index over a scale.

Electric-Current Meter, J. W. T. Olan, 470,441. Filed June 6, 1891.

Claim 1 follows:

Combination in an electric meter of a vessel containing a liquid, a balanced float in said vessel and movable therein, said float having the forward movement only while the meter is in use, means for disturbing the balance in accordance with the current measured so that the float will move, and a recording mechanism operated by said movement.

Metallurgical :—

Magnetic Ore Separator, C. T. Thompson and R. N. Sanders, 470,455. Filed Apr. 16, 1891.

Magnetic Ore Separator, C. T. Thompson and R. H. Sanders, 470,456. Filed Dec. 5, 1891.

Miscellaneous :—

Purification of Brine, C. G. Collins, 470,181. Filed May 2, 1891.

Consists in introducing an independent supply of oxygen into the brine and subjecting the latter to a current of electricity.

Electric Gas Lighting Burner, H. A. Pinkham, 470,256. Filed Sept. 25, 1891.

Electrical Attachment for Pianos, F. A. Feldkamp, 470,294. Filed Nov. 9, 1891.

Electrical Wire Stripper, A. Cuthbert, 470,318. Filed Oct. 6, 1891.

Push Button, C. H. Delano, 470,372. Filed June 2, 1891.

Has for its object the exclusion of dust.

Electric Store Service Apparatus, M. W. Hassan, 470,428. Filed Feb. 2, 1891.

Dice-Box, F. W. Mader, 470,498. Filed Oct. 9, 1891.

Lightning Conductor, H. Simpson, 470,514. Filed Sept. 9, 1891.

Machine for Heading Spokes, T. Hill, 470,566. Filed Nov. 22, 1890.

An electric machine for securing the spokes to the rims of wheels and pulleys.

Electric Circuit-Closer, G. W. Price, 470,596. Filed Nov. 18, 1889.

A circuit-closer for door pulls, etc., consisting of a coiled helical spring which completes the circuit when elongated and breaks it again upon being released.

Electric Dust-Collector, R. E. Wardhaugh, 470,608. Filed Oct. 2, 1889.

Railways and Appliances :—

Electric Railway, E. Thomson, 470,221. Filed Oct. 9, 1889.

Consists of a series of pivoted contacts normally out of electrical connection with the main line, each contact pivoted to swing in the direction of movement of the vehicle and make connection during the passage of such vehicle.

Electric Car-Brake, J. Redmond, 470,505. Filed Oct. 17, 1891.

A brake for railway cars electrically actuated.

Electric Locomotive, E. A. Sperry, 470,516. Filed June 11, 1891.

Claim 1 follows :

In a power gearing for electric cars an electric motor, a hollow armature shaft for said motor, a power-transmitting shaft within the armature shaft connected by gearing to the car axle, an elastic or cushion connection between the two shafts and a rigid frame for the motor, elastically supported from the truck frames, whereby the motor may be located between the axles and permitted to vibrate independently of such axles.

Electric Locomotive, S. P. Hollingsworth, 470,627. Filed Dec. 15, 1891.

Claim 1 follows :

In an electric locomotive the combination of a continuously-running motor, the vehicle wheels and axles, a clutch member connected to the wheels by flexible couplings, a clutch member connected to the motor, a liquid for connecting the two clutch members and mechanism for controlling the flow of the liquid.

Switches and Cut-Outs :—

Electric Cut-Out and Safety Device, C. R. Meston and A. W. Meston, 470,204. Filed Jan. 12, 1891.

A ceiling rosette for incandescent lamps.

Safety Cut Out, M. Kerstein, 470,382. Filed June 8, 1891.

Claim 1 follows :

A combination of an electric wire composed of sections and provided with slip joints to connect the sections, of supports for the said sectional wire, and springs connected at one end to one of the said supports and at the other end to one member of the said slip joints.

Telegraphs : -

Telegraph Relay, C. M. Dyer, 470,557. Filed Sept. 9, 1891.

Provides a nicely balanced armature held in proper adjustment without regard to the variations of the electric current.

Telephones and Apparatus:—

Telephone, W. A. West, 470,634. Filed Nov. 12, 1883.

A reinforcing device which may be placed at any intermediate point of the telephone circuit and used as a relay, and which may also be used as a receiver or transmitter as desired.

THE NEW STATION OF THE BROOKLINE GAS LIGHT CO.[1]

BY ROBERT AMORY, M. D.

From the experience in our electric light station in Brookline, we carefully considered a plan of construction in our new station which should provide commodious and convenient access in all its parts, and especially with a view to economical administration. We consulted expert engineers, and finally decided to employ as our adviser Mr. Fry, chief engineer of the United States Treasury Building, in Boston. The result of a study and careful consideration of the problem, with both Mr. Isbell and Mr. Fry, is the present building, devoted to the creation, evolution and distribution of electrical force and its conversion into light.

The building, which is entirely of one story in height, is arranged with a boiler-room for eight so-called 125 h. p. boilers, but which are fitted with Smith's patent settings and feed-water circulation so as to produce about one-sixth more horse power than is commonly obtained from boilers of that size.

The belt from the engine pulley operates on a shaft built upon a brick foundation seven feet in height on a concrete bed seven feet deep, the bottom layer of the concrete resting upon the cribbing of a plank and timber foundation upon the top of the piles. This masonry bedding has no connection with the walls of the building.

The main countershaft is provided with positive clutches, the unlocking of which allows its separation from the motive power of any one or two of the three engines, whose unit power is 100 h. p., 150 h. p., 250 h. p., or 500 h. p. ; total, 750 h. p.

Briefly, the new electric and power plant, when complete, consists of a steam generating capacity of 1,200 h. p., using eight horizontal tubular boilers. In the future, if higher pressure or more power is desired, this capacity can be increased by using some form of water tube generator to a limit of 1,800 h. p. at 140 lbs. pressure. At present, three new horizontal tubular boilers are in service. The power portion, when complete, will consist of two 500 h. p. engines, one 100 h. p. engine and one 150 h. p. engine. Of these, the two latter are now in use at the old station. The one 500 h. p. engine, which has been installed, is a twin compound engine, constructed by the Armington & Sims Engine Co., of Providence. The cylinders are 21 × 31 inches, with a stroke of 18 inches, and the speed will be from 200 to 225 revolutions per minute. The engine is piped in a manner devised by Chief Engineer Fry of the United States Treasury Service so that either cylinder can be used, if necessary, independently of the other, either at a high pressure or as a simple condensing engine ; the two ordinarily operating as a compound condensing engine. By this arrangement, scarcely any accident can wholly deprive us of at least one-half of our main source of power. The use of this engine and the application of a condenser to the larger of the two engines to be brought from the old station, will effect a large proportionate saving in fuel over our present consumption, probably, at least 10 per cent. The shafting erected provides for a capacity of eight 50-light arc dynamos and three 1,000-light incandescent dynamos, and may be readily extended so as to admit of an increase of 100 more arc lights and 2,000 more incandescents at a relatively small expense. The shaft is so arranged that any one of the engines can drive the whole line, an important safeguard against total breakdown. The use of the Evans system for driving the arc dynamos obviates the use of much belting and so reduces the floor space required that, combined with the type of engines and arrangement of the shafting, we have all our motive steam and electric apparatus, aggregating 1,250 h. p. in one room 60 × 105 feet without undue crowding ; a greater economy of room than is known in any electric plant in New England or elsewhere. The steam piping, including that which supplies the heating system and the gas works, is designed for a working pressure of 125 lbs., and is so arranged that any boiler may be cut out at any time without interfering with the others.

In short, the entire plant has been put up in accord with modern practice, and, compared with others, at a moderate expense, keeping always in view the necessity for a possible growth, and prepared for that growth by methods of improved design and construction.

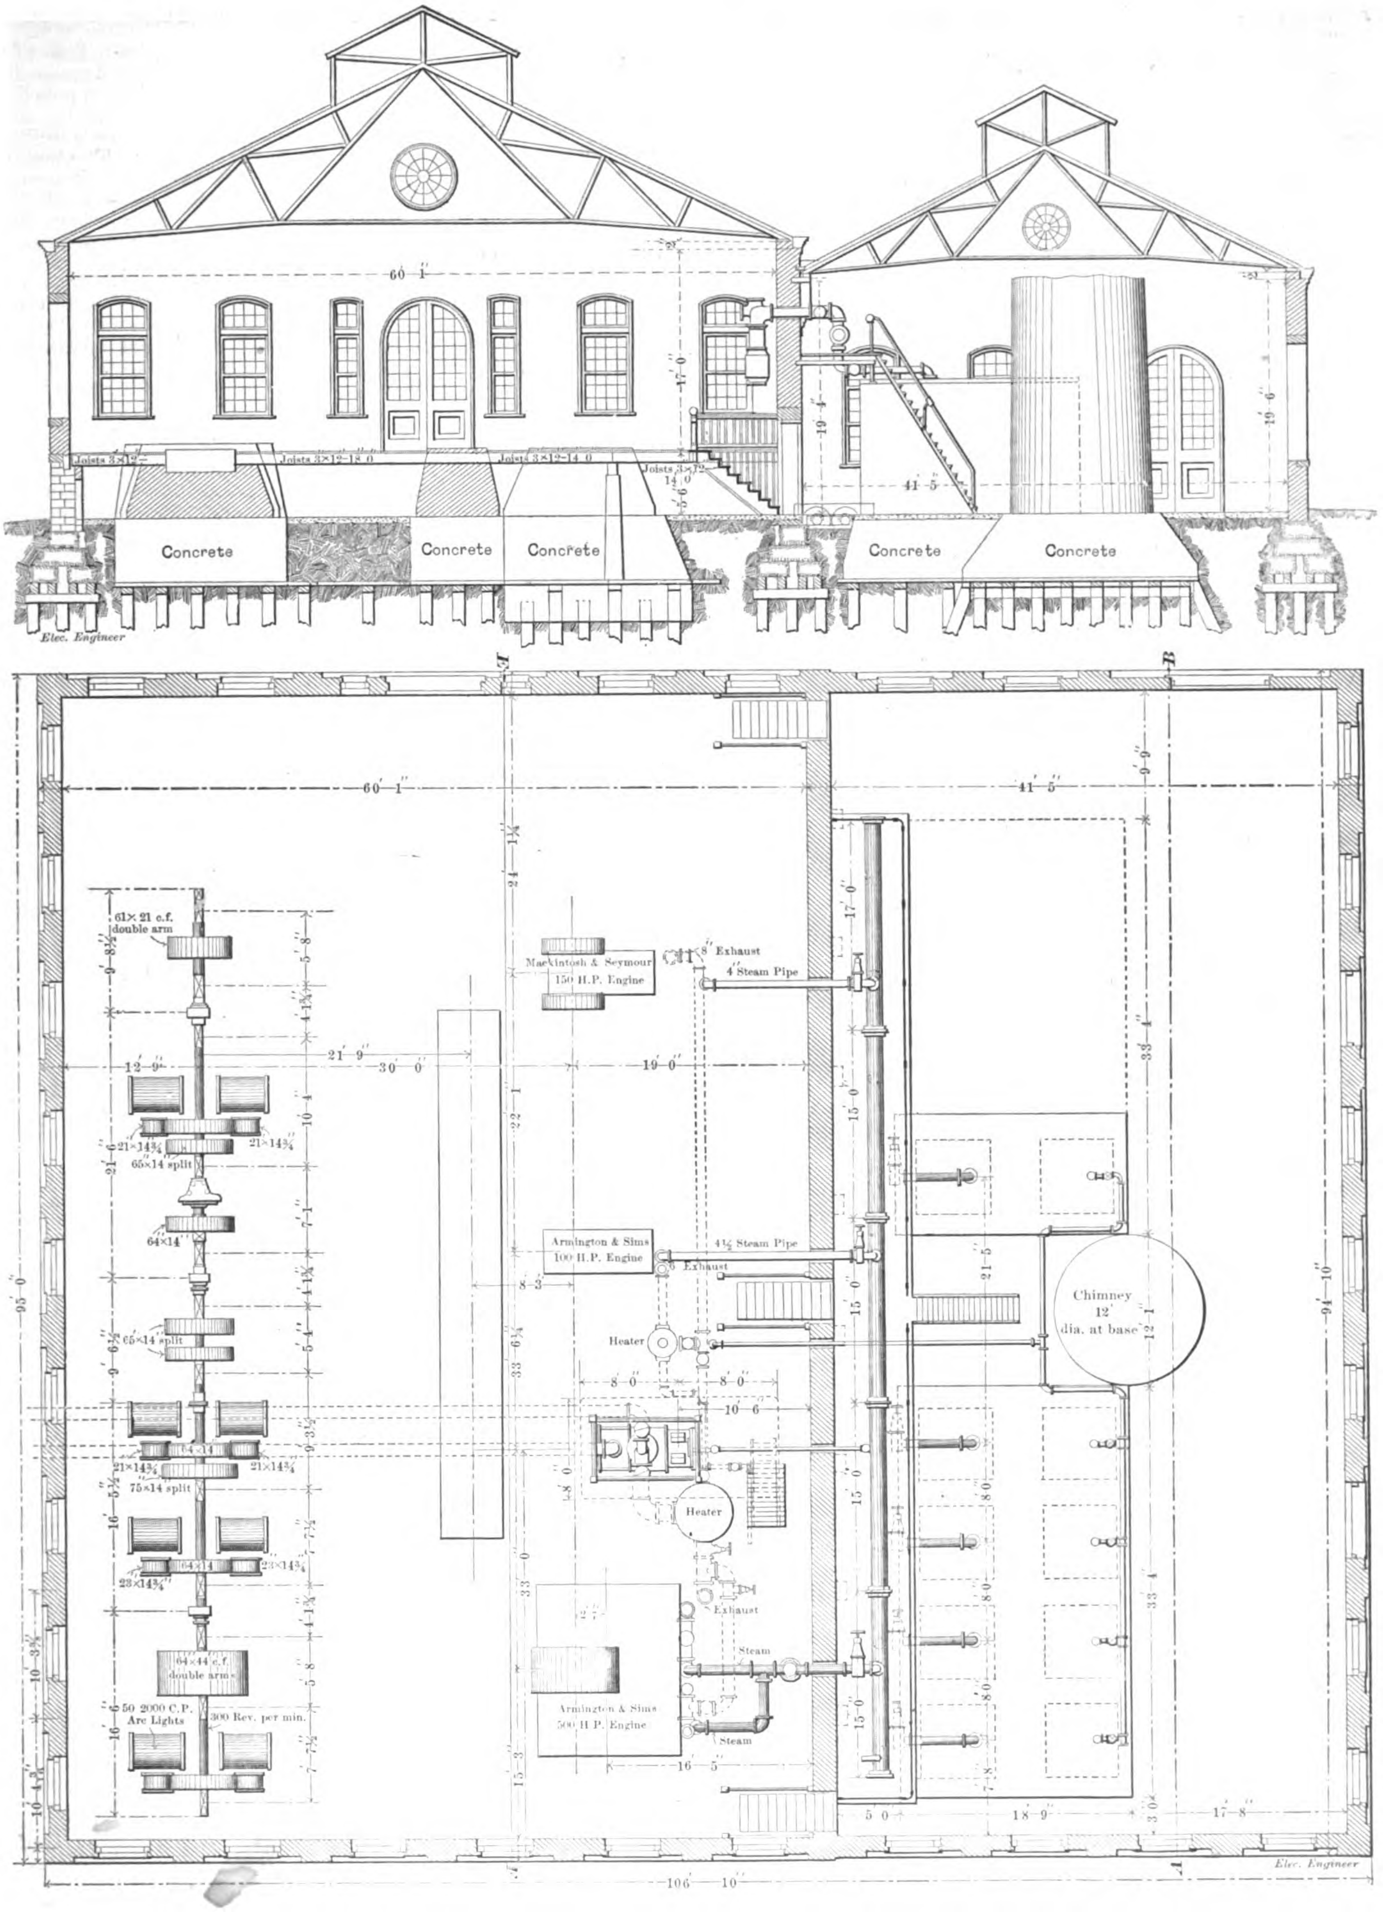
The incandescent dynamos at present to be run on the alternating system receive their motion from the countershaft (described above) by belting back to their position on the middle brick pier situated between the engines and the shafting beds.

By means of a newly devised switchboard, we can throw any one or more of these dynamos upon one circuit without the danger of running them in multiple or parallel with each other.

Finally, there is no combustible material in any of this construction ; even the switchboard and roof being formed of iron and slate, the roof being built by the Boston Iron Bridge Works, of Boston. There was one obstacle to this form of construction which, at first, seemed difficult to avoid, viz., the condensation of water upon the inside of the iron trusses and purlins of the roof. We borrowed here a simple device in use on our iron and steel

---

[1] Abstract of a paper read before the New England Association of Gas Engineers at their annual meeting, Feb. 18, 1892.



The New Electric Light Station of the Brookline, Mass., Gas Light Company—Plan and Section—(See page 284).

cruisers; we painted the inside of the iron and slate roof with ground cork and lead paint, which provides an air space around the metal and thus prevents the warm air from being condensed on the surfaces of the metal and slate.

The floor of the dynamo house is constructed of wood, which is entirely supported from the piling foundation, independent of the walls, and is the only combustible portion of the building. We thus save in insurance premiums annually $1,000.00 at the least estimate. We take out insurance policies only on coal house, office and stable buildings, and a very small amount on the purifier, condenser and meter houses, saving the premium on the value of about $200,000.

Personal.

COL. J. F. DILLONT, who has been business manager of *The Electrical World* for a little less than two years, has resigned, and will hereafter have no connection with that paper. During his stay in the electrical field, Col. Dillont has won a good many friends, all of whom will wish for him peace of mind and prosperity on the staff of the *Architectural and Building Monthly*, which he now joins.

A CORRECTION.

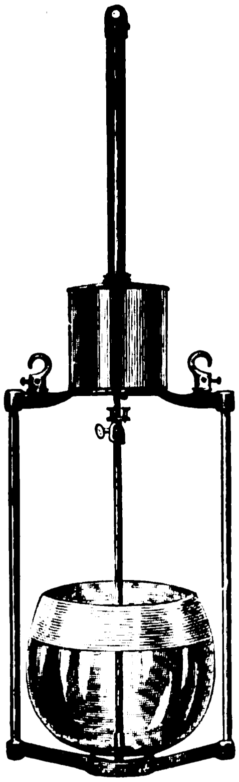
In our review of Trevert's "Armature and Field Magnet Winding," last week, it was erroneously stated that the price is 50 cents. It should be $1.50.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT

"Ads." are to business what feeders are to the trolley wires.

THE DUPLEX ELECTRIC CO.'S ARC LAMP.



Duplex Arc Lamp.

THE arc lamp shown herewith is manufactured by the Duplex Electric Co., Limited, of Corry, Pa., to burn on either arc or incandescent circuits. The lamps are ornamental in appearance and simple in construction. They are fitted with hand cut-outs, automatic cut-outs, and automatic short circuit, which removes all resistance, as well as the lamp, from circuit when the carbons are consumed, and which allows single and "twin" carbon or all-night lamps being operated on same circuit with safety. The frame of this lamp is wide, and was especially designed to overcome the objectionable feature of casting large shadows. It is perfectly insulated, so as to be handled with safety when in circuit.

The carbons are fed by a train of gears that are controlled by differential magnets, which cause a uniform feed, and, consequently, a steady, noiseless, white light. These gears are connected so as to allow a rapid upward movement of the feed rack to facilitate trimming. They do not stick even when exposed to constant bad weather.

The "Duplex" lamp is easily adjusted to any length of arc desired, and when once adjusted it does not easily get out of order. It is made in two different styles, single and twin carbon. Both styles are made to give a light of either 1,200 or 2,000 normal c. p , and the twin carbon lamp is practically the same as the single carbon lamp with the exception of a carbon holder.

In the "twin" lamps the advantage is that when burning on one side of the twin carbon, the heat created by the arc heats the other side, and by being kept hot the arc is started before the eye can discern the change. As both sides are burnt to a point and apart, practically no shadow is cast except by the frame.

This lamp is highly appreciated by those who have used it, as, besides the above, it requires little time in trimming, is little liable to get out of order and is practically noiseless.

THE MILLIKEN PATENT POLES.

A VERY interesting and valuable pamphlet has been issued by Milliken Bros., of 55 Liberty street, this city, on their poles for electric railway and electric light plants. The subject of pole line construction and pole strength, is discussed in an able and instructive manner, and the various features of merit in the Milliken iron poles are carefully and fully set forth. The textual matter, which is in reality a brief treatise on iron poles, is accompanied by data of exacting tests made by Prof. Thurston, at Cornell University, and by a variety of diagrams, sectional views, and perspectives, showing just what the poles are and how well they look when up. The pamphlet is one of the best pieces of technical trade literature that we have seen in a long time. Most of the pictures have a familiar look, we may say, to the eyes of those who were recently delegates to the Buffalo Electric Light Convention, as the streets of Buffalo have some 5,000 or 6,000 Milliken poles distributed through them in electric railway work.

"JOHNSON SWITCHES."

WE have received a very handsome catalogue pamphlet of the above title from the Interior Conduit & Insulation Co., of this city. It is got up in the best Bartlett style. The subject-matter is the new Johnson "vise" snap switch which is attracting so much attention. The pamphlet contains a reprint from this journal of the excellent article by Mr. E. H. Johnson on his invention, together with details as to tests made, The arguments assembled in the pamphlet are made very convincing by the presentation of full size cuts showing exactly the dimensions of the 50 and 100 ampere switches, which under former conditions would not take care of a quarter of such a quantity of current, but which, on this new principle, do their work so well that they even seemed to be underrated by the makers.

SCHIEREN BELTS IN ENGLAND.

THE following is of interest as showing appreciation of American products in England:

THE ROUNDHAY ELECTRIC TRAMWAY,
LEEDS, ENGLAND, Jan. 16th, 1892.

MESS. CHAS. A. SCHIEREN & CO.,
47 Ferry Street,
New York, U. S. A.

GENTLEMEN:

We are ordering to-day from you a supply of your "Electric Belt Stuffing," also a supply of your "Belt Cement."

Will you kindly send us full instructions for splicing your Perforated Belts? It may interest you to know that the two belts furnished by you for this plant are giving every satisfaction, and have elicited considerable admiration from English engineers.

Yours truly,
THE ROUNDHAY ELECTRIC TRAMWAY,
J. E. WINSLOW, Manager.

GUM-ELASTIC ROOFING.

THIS material, first brought before the public twelve years ago, is now in use on buildings of every description throughout North and South America, and the fact that the demand is as great as ever seems to indicate general satisfaction. Gum-elastic roofing is made of felt, saturated with compounds of gum and dead oil, and rolled under hydraulic pressure until it becomes a strong, pliable, compact and cleanly material, unaffected by extreme changes of temperature, and absolutely fire and water proof. It may be applied by any ordinary workman, and is claimed to outlast tin, zinc and iron roofing, while costing considerably less.

The roofing, as well as the cement and paint of the same name, is manufactured and sold by the Gum-Elastic Roofing Co., of 39 and 41 West Broadway, New York City.

THE SOUTHERN ELECTRICAL MANUFACTURING AND SUPPLY CO.

THE above concern has its headquarters at 110, 112 and 114 Baronne street, New Orleans, with a factory in the same city. Mr. E. L. Bemiss is the president and Mr. W. Oswald, a pioneer motor man, is secretary, treasurer and general manager. The company undertake the whole range of electrical work. They are making a specialty of motors up to 5 h. p., but are principally busy on $\frac{1}{8}$ h. p. fan motors, of which they have already sold about 200 of their own make.

MR. CHARLES F. PEASE, formerly manager of the Westinghouse Electric Co., has been appointed general superintendent of the Interior Conduit and Insulation Co., with full authority over all the manufacturing, shops, etc. The company will immediately devote itself to getting out a line of special appliances, of the nature of the Johnson switch. Mr. P. H. Klein, who has been acting as superintendent of the company's factory, has resigned and will connect himself with one of the fixture houses.

SOMOFF'S INCANDESCENT LAMPS.

Mr. J. L. Somoff, of 1 Ann street, this city, is adding largely to his special makes of small incandescent lamps, of high and low voltages. Some of the new shapes devised by him are extremely pretty, so much so, that we can readily believe in their power to induce people to try new decorative effects for balls, dinners, lunches, receptions, etc. Mr. Somoff's prices are very moderate, and he deserves all the trade he can get.

THE BOSSERT LIGHTNING ARRESTER.

The approach of the summer season, accompanied, as it usually is, by heavy thunder storms, renders it advisable for the central station manager to make provision for the thorough protection of his lines and apparatus from lightning. Experience has taught that the best way to render lightning harmless, is to provide ready and easy means for its escape to the ground.

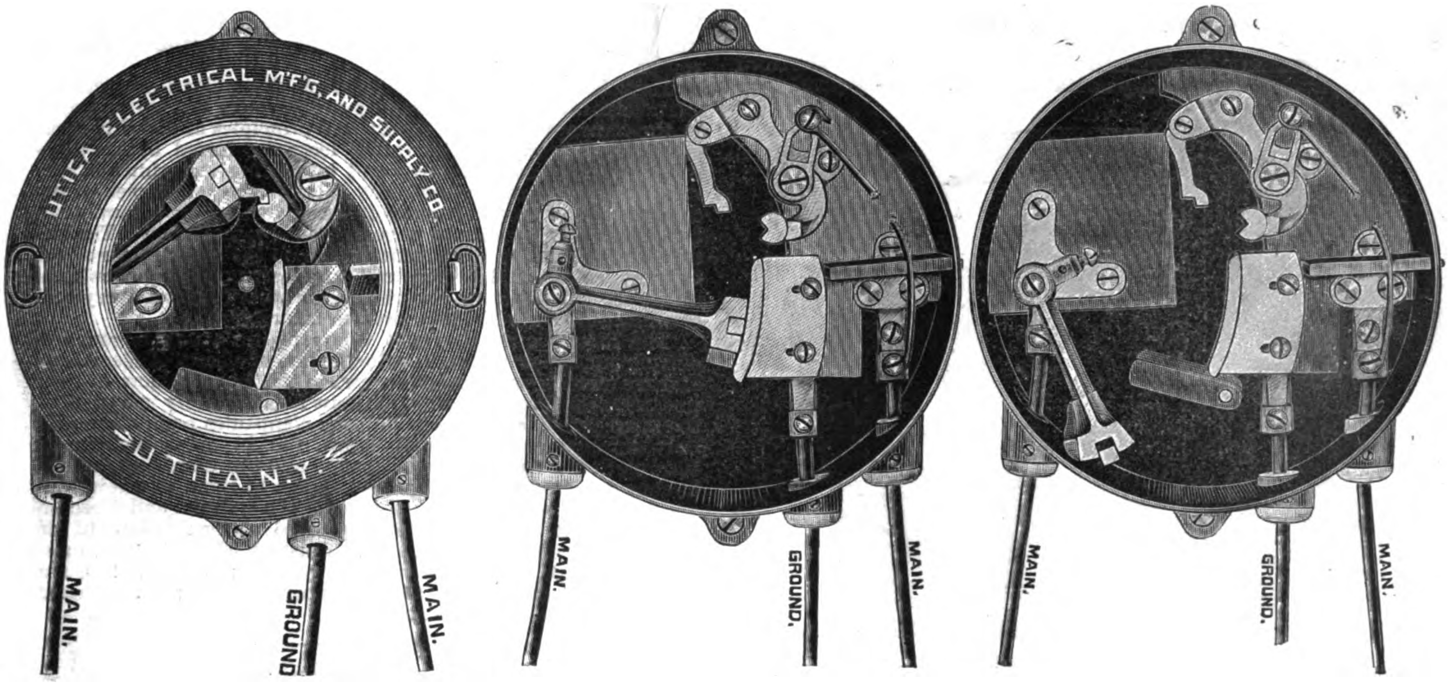
The Bossert lightning arrester, shown in the accompanying illustrations, is peculiarly simple and absolute in its action. No extra resistance is introduced into the line. The contacts are sufficiently large to carry heavy lightning discharges, the only injury to the apparatus being the melting of a fuse wire.

In the illustrations, Fig. 1 shows the arrester connected in circuit. The metal parts are mounted on slate bases and the whole is enclosed in water in a tight iron case.

Fig. 2 is designed for the protection of arc and incandescent circuits. It shows the position of the arrester after being struck by lightning. There is no resistance offered to the lightning, and the ground connection being perfect and quickly made, there is a ready means for its escape without flashing.

Fig. 3 is especially designed for the protection of railway generators and motors where part of the circuit is made by ground. In this arrester, ground connection is made just long enough for the discharge of the lightning and is then broken quickly in order to avoid the short circuiting of the generator. Arcing is prevented by a piece of slate actuated by a spring and interposed between the ground plate and the connecting arm.

These lightning arresters are manufactured by the Utica Electrical Mfg. & Supply Co., of Utica, N. Y.



Figs. 1, 2 and 3.—The Bossert Lightning Arrester.

THE INDURATED FIBRE PIPE.

The Fibre Pipe Company, of New York City, with works at Mechanicville, N. Y., are the sole manufacturers of fibre pipe, and they control exclusively the basic patents, taken out by H. J. Medbery, and others, covering all known methods of making fibrous pipe treated with a preservative compound. They are also sole owners of the McMahon patents on spiral paper tubing for interior conduits.

Briefly, the process of manufacture may be described as follows: The pipe is made from long fibres, separated, washed free from all saps and gums, moulded while in a pulpy state into the requisite size and shape and then subjected to great hydraulic pressure, after which it is treated and hardened by a chemical process that makes it completely impervious to moisture, acids or gas and without injurious effect upon wire or cable insulators. The weight of the pipe is one-fourth that of iron and is therefore more easily handled and transported to the trenches, ready for the laying.

It is considered that this pipe is perfectly adapted for the uses of an underground conduit for electric wires, and is believed to secure the greatest *safety, permanency and economy* in subways for the following reasons:

1. It is an absolute non-conductor of electricity.
2. It resists the action of the gases and acids of the earth.
3. Is not subject to disintegration.
4. It is moisture-proof throughout its entire structure.
5. The abrasion of its surface does not impair it.
6. It forms an absolute insulation for naked wires.
7. It does not contract or expand from thermal changes.
8. It is strong and light.
9. It has successfully withstood the test of five years for subway work.

We understand that electrical tests have been made by prominent electricians, and it has been reported that 2,000 volts had no effect on pipe shell three-eighths of an inch thick. The electrical resistance measured infinity. The breaking strain was found sufficiently high to prevent accidents from any ordinary weight or pressure. The screw or socket joints were found sufficiently strong and close for any underground pressure liable to occur. These and other results of tests were mainly from experiments with wires and cables for electric light uses; but the pipe is used largely for street railway, telegraph, telephone and special signaling systems.

The same company are also exclusive manufacturers of the Medbery patent "Multiple Duct" for electrical subways. New and specially designed machinery is used in the process, and fibre pipe of remarkable hardness and perfection of smooth ducts and close joints is produced in uniform lengths of five feet with ducts of various sizes and of any required number. Preference is given to the four duct pipe, round bore and square exterior, this form having already been determined upon by the telephone companies and others as convenient and economical for "building up" in subways.

The facility with which the pipe can be laid is one of the strongest points in favor of its use. The lightness of the pipe, its symmetrical form, and the ease with which tight connection is made by exact screw or socket joints, sealed with a small quantity of hot asphaltum, enable the laying of the pipe to be accomplished quickly and economically.

THE PENNSYLVANIA ELECTRIC ENGINEERING CO.

The Pennsylvania Electric Engineering Co. has been incorporated with $25,000 capital, and the following officers elected for the ensuing year: Arthur L. Bosley, president and manager; Benj. W. Tingley, vice-president; Lewis R. Schultz, secretary and treasurer; and Fredk. S. Koons, assistant secretary.

QUEEN & CO.'S TESTING SETS.

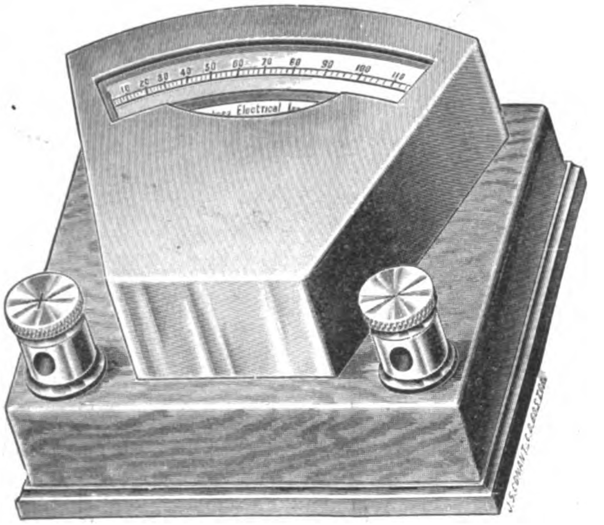
WE are informed by Queen & Co. of Philadelphia that their portable testing resistance sets still meet with great favor wherever they are introduced. The new style known as the "1891" type, which was brought out last fall, is especially appreciated as its peculiar construction has overcome many previous difficulties in both outside and inside testing. As is well known, great trouble has been experienced with the galvanometers usually supplied for such work, those with fibre suspension being too delicate for street use or where running machinery jars the station, and those moving on a central point being too sluggish. To overcome these defects, Queen & Co. devised a new galvanometer which, as has been proved by use, meets the requirements of all-around testing to a most satisfactory degree.

The features of this instrument which render it of such value are deadbeatness and sensibility. In consequence it is not affected by mechanical vibrations and proximity to masses of iron or intense magnetic fields, and can be used alongside of dynamos when running, in the streets of large cities, on shipboard and in fact everywhere. The coils in the rheostat and bridge are wound with platinoid wire and guaranteed accurate to one-fifth of one per cent. A special "reversing attachment," employed by Queen & Co. in their standard resistance boxes, is supplied, which gives a maximum range from .001 to 11,110,000 ohms.

The makers have just issued a neat circular No. 285 which sets forth the advantages of their testing sets, and we have no doubt they will gladly send a copy of the same to interested parties.

WHITNEY VOLTMETERS AND AMMETERS.

THE WHITNEY ELECTRICAL INSTRUMENT Co. of 35 Hartford street, Boston, with factory at Manchester, N. H., are placing on the market a voltmeter and ammeter intended specially to meet the growing demand for cheap but accurate apparatus, in stations, power houses, tests, etc. A cut is shown herewith. The instrument is direct reading and can be furnished to be used in either a horizontal or an upright position as desired. The divisions of the scale are very nearly uniform, facilitating close and accurate readings, and the low price of the instrument enables every user of electrical apparatus to make proper tests of it and of his circuits without feeling the expense of the necessary appliances.



WHITNEY VOLTMETERS AND AMMETERS.

"HARRISBURG" IDEAL ENGINES ON STEAMBOATS.

DURING the past few months, W. R. Fleming & Co., 174 Fulton street, New York, have been equipping a number of steamboats with their "Ideal" self-oiling automatic cut-off engines. The first boats supplied with this engine were the steamships "Yumuri" and "Maverick," of Ward's Line, which, proving to be perfectly satisfactory, have been followed by those of the Pacific Mail Steamship Company's boats, "Havana," "America," "Newport," "Para" and "Rio Janeiro" besides a new vessel not yet completed at Chester, Pa., and another at San Francisco, for which the engines have just been shipped. The Pennsylvanai Railroad Company have the "Ideal" engines on their new ferry-boats "New Brunswick," "Cincinnati" and "Chicago." The Spanish Steamship Line have the same engines on their steamers "Savannah" and "Ciudad Coudal" running between New York and Cuba, these being directly coupled to multipolar dynamos.

A NEW WIRT DYNAMO BRUSH.

PROBABLY the one thing about a dynamo or motor which causes more anxiety than any other is the tendency to spark and flash at the brushes. Numerous devices and lotions have been invented to smooth the sometimes ruffled temper of the commutator, but with indifferent success. Mr. Chas. Wirt has recently designed a new brush which seems to accomplish a great deal in this direction. It is manufactured by the Electrical Supply Co., and is meeting with an extensive sale. The company has received many letters from engineers and station managers expressing considerable satisfaction with the results obtained.

PARTRICK & CARTER CO.

IN our advertising columns last week will be found an illustration of the well-known and popular Partrick & Carter Co. patent needle annunciator. This firm are the only makers of the original needle annunciators which are made under U. S. patents of recent date which do not expire for some years. The features and advantages of this annunciator are too well known to require an extended notice. They are made up in various styles of cases and woods, with or without return calls and fire-alarms.

AN INTERESTING LECTURE ON ELECTRICITY.

THE first of a series of instructive lectures on the subject of electricity and its industrial applications was given on Saturday afternoon, January 30, to the employees of the Ries Electric Specialty Company, at their office and factory, Nos. 324 to 330 West Baltimore street, corner Eutaw, by the president of the company, Mr. Elias E. Ries, the well-known electrician and inventor.

These lectures, which are to be given at regular intervals, are intended to familiarize the young men and young women employed by the company with the theory and principles underlying their practical daily work. The initial lecture referred to was illustrated by numerous attractive and interesting experiments, and was thoroughly appreciated not only by the employees of the company, for whose instruction it was given, but by a number of ladies and gentlemen who were present by invitation. The lecture was held in the large testing-room on the second floor of the building, corner of Baltimore and Eutaw streets, which was fitted up for the purpose with electrical apparatus of almost every conceivable kind from Mr. Ries' private laboratory.

The Ries Electric Specialty Company are busily engaged in getting out a new and very valuable line of electrical specialties, and are meeting with much success in the introduction of their new regulating socket, which is now being rapidly adopted by the most prominent electric lighting companies and others, not only throughout the United States, but in many portions of Europe, South America and Canada, and the management is to be congratulated upon the interest shown by them in the welfare and advancement of their employees. The officers and directors of the company, which was incorporated under the laws of the State of Maryland in June, 1891, consist of Elias E. Ries, president; Lewis S. Greensfelder, vice-president; Leopold Ries, secretary and treasurer; David Myers, superintendent; and Herman Ries, assistant superintendent.

F. P. LITTLE & CO.

THE above firm of 141 East Seneca street, Buffalo, N. Y., have just closed a contract with the Western Transit Co. for lighting their city elevators "A" and "B." The contract includes a 7 by 12 Rice engine manufactured by the John T. Noye Manufacturing Co.; one E. I. cylindrical type Thomson-Houston dynamo; the necessary wiring and equipment for 300 incandescent lights of 16 c. p. and 4 arc lights to be run from the same circuit. F. P. Little & Co. are also to erect a 10 by 25 by 13 foot brick building in which to put the plant.

THE BERLIN IRON BRIDGE COMPANY.

THE TRUE BLUE MARBLE COMPANY, of Rutland, Vt., will replace the mill lately destroyed by fire, with an iron building, and have placed the contract with the Berlin Iron Bridge Company, of East Berlin, Conn. The building will be composed entirely of iron and marble, and will be 80 feet in width and 254 feet in length, the side walls being of iron and marble and the roof of corrugated iron. Not only the entire building will be of iron, but the framework inside for carrying the gang saws, shafting, etc., will be of iron, so that there will be no woodwork about the building in any way to take fire.

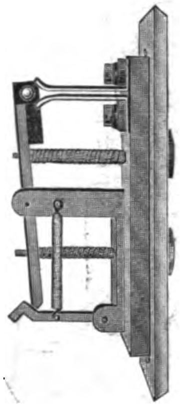
ENGINE AND BOILER WANTED.

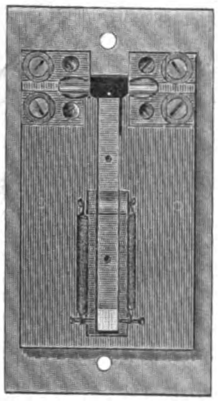
WE understand that the Excelsior Electric Co. of Harrison, N. J., are in the market for a 250 h. p. engine and corresponding boiler capacity.

THE "P. & M." PUSH-BUTTON SWITCH.

We illustrate in this issue an article long desired by the trade, for which there is a pressing demand and whose introduction will go far to obviate many defects of the present methods of incandescent lighting in finely furnished and decorated houses.

The Southern Electric Company, of Baltimore, Md., have patented and put on the market a push-button switch, under the trade mark of "P. & M." They are made of different sizes, from 5 to 50 amperes. The face plates are made of either brass, nickel, or oxidized silver. It is set flush in the wall and there is nothing to mar the harmony of the decoration. It is shown in Figs. 1, 2, 3 and 4.

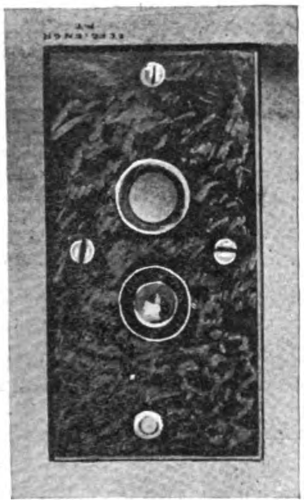


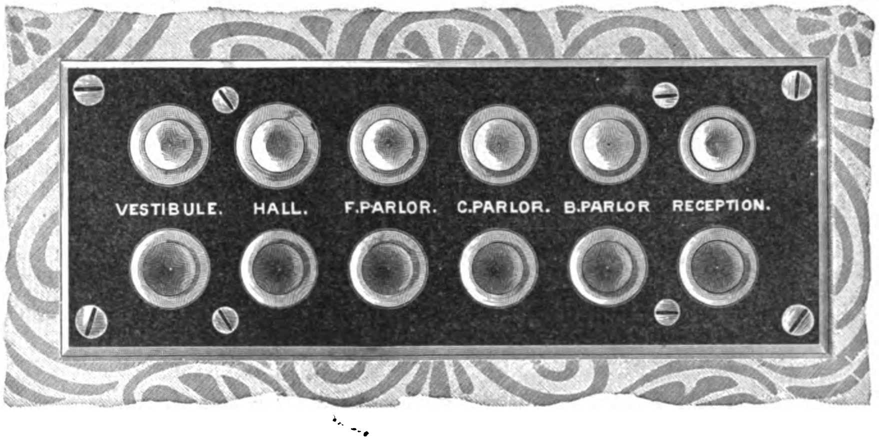


Figs. 1 and 2.—The "P. & M." Push-Button Switch.

Indeed, the only parts necessarily visible are the black and white buttons, whose condition—loose or firm—will indicate to the touch whether the light is lit or not. The switch is made either double or single pole; the mechanical movements are simple, exact and effective. The white button lights the lamps; the black one extinguishes them. The compactness of the article and the extreme simplicity of its details are all well shown in the cuts, all of which are half size.

One illustration shows a bank of six such switches as arranged in the residence of Gen. Thos. J. Shryock, Grand Master of Masons of the State of Maryland. In the small space of 3 x 8 inches it controls 30 lamps.





Figs. 3 and 4.—The "P. & M." Push-Button Switch.

SALES OF BALL ENGINES.

The following recent sales are reported by the Ball Engine Co., of Erie, Pa.: John Becker, Fitchburg, Mass., one 35 h. p. simple engine; Thomson-Houston Co., Boston, Mass., one 100 h. p. simple engine; Lewis Benedict, Attica, N. Y., one 80 h. p. and one 50 h. p. simple engines; William Howell Caldwell, Union City, Tenn., one 80 h. p. simple engine; Newark Electric Light Co., Newark, N. J., one 300 h. p. cross, compound engine; Hygeia Hotel, Old Point Comfort, Va., one 60 h. p. simple engine; Gale Shoe Mfg. Co., Haverhill, Mass., one 35 h. p. simple engine; Kittanning Electric Light, Heat & Power Co., Kittanning, Pa., one 150 h. p. simple engine; New England Conservatory of Music, Boston, Mass., one 35 h. p. simple engine; Columbia Electric Light Co., Philadelphia, Pa., one 200 h. p. simple engine; Osage Electric Light Co., Osage, Iowa, one 50 h. p. simple engine; Commonwealth Iron Co., Commonwealth, Wis., one 35 h. p. simple engine; Eugene Sites, Loraine, O., one 100 h. p. simple engine; Hix, Crosby & Co., Richmond, Va., two 60 h. p. simple engine; Edison Light & Power Co., Minneapolis, Minn., one 300 h. p. cross-compound engine; Schmidt Building, Pittsburgh, Pa., one 35 h. p. simple engine; Vandergrift Building, Pittsburgh, Pa., one 60 h. p. simple engine; Central District Telegraph & Telephone Co. Building, Pittsburgh, Pa., two 50 h. p. simple engines; Pittsburgh Iron & Steel Engineering Co., Pittsburgh, Pa,, one 80 h. p. simple engine; Industrial Improvement Co., Brockton, Mass., one 300 h. p. and one 100 h. p. cross-compound engine; Palace Hotel, San Francisco, Cal., one 200 h. p. cross compound engines; Halifax Mfg. Co., Lake Village, N. H., one 35 h. p. simple engine; Lockport Gas Light Co., Lockport, N. Y., one 100 h. p. simple engine; Electric Improvement Co., San Francisco, Cal., one 100 h. p. tandem compound engine; S. J. Lefevre, Gibson City, Iowa, one 100 h. p. simple engine; Edison General Electric Co., Portland, Ore., three 150 h. p. simple engines.

THE TRIUMPH COMPOUND ENGINE COMPANY.

The Triumph Compound Engine Company, of Cincinnati, O., report business as brisk. Their engines have been running in various parts of the country for several years and have practically demonstrated themselves to be all the makers claimed for them. Besides having improved their valveless engines where experience has shown it to be advisable, this firm is about to put on the market a compound automatic and a small single cylinder engine enabling them to more fully supply the various demands of the public. They are well equipped for this work, their shops being filled with specially designed tools, and their aim is to furnish engines of the latest and most approved design at prices that will place them within the reach of all.

AMSTERDAM, N. Y., NOTES.

Some quick repair work was done by the company during the recent storm which swept over Amsterdam. Almost simultaneously a falling pole demolished an arc circuit, while a ground on the railway line caused the breaking of a generator belt which tore away the brushes of an incandescent dynamo. In thirty-five minutes all three circuits were again running.

The central station of the company has been reconstructed and new foundations placed under each machine. Three new switchboards are soon to be built to control separately arc, railway and incandescent work. They will be built of wood, covered on the outside by a layer of asbestos, and all wiring will be done at the back.

The Amsterdam Street Railway Company will soon extend its lines to Rockton. A large number of the citizens favor the movement and on the hearing granted by the council on February 26, permission was given, and work begun at once.

Amsterdam has a long grade of 13¾ per cent. with two curves, probably the worst in the country. It has been found that when two motors of different speeds have been put on one car together, the hindrance has been very great in some instances.

THE HOGGSON PERPETUAL CALENDAR, DATE AND TIME STAMP.

In modern business methods there is nothing more important than to know with unfailing accuracy not only the date of the receipt of any communication, but also the exact minute that the matter was received. To accomplish this end, for several years past mechanical inventors have been working out and placing on the market various types of time stamps. These, however, were apt to be cumbersome and, owing to their being operated by a blow, often wore out and became inaccurate, and at the same time were exceedingly costly pieces of mechanism. To overcome these difficulties and produce a stamp of absolute reliability and accuracy, and at the same time at a price within the reach of all, Mr. Samuel H. Hoggson has perfected the instrument shown in the accompanying illustrations.

In the first place it is asserted that the stamps with metal type wheels, using an ink ribbon and operated by a blow were unreliable and incapable of indefinitely withstanding the hard treatment required to work them, together with the fact that printing the time and date in a straight line as they did, the impression occupied too extended a space to enable it to be used in postal service and on railroad tickets. For this service heretofore ordinary hand-stamps have been used exclusively. These stamps require to be set by hand at frequent short intervals, entailing a large amount of labor without giving the correct time, to the minute, and bringing in an extensive factor of error due to negligence, intentional or otherwise.

It was speedily determined that the keynote overcoming the above-mentioned difficulties could only successfully be struck by the introduction of an entirely new principle of printing, which has been successfully accomplished and is used in these new stamps. The entire working mechanism is contained in the head of the stamp, occupying the small space of 2 x 2⅛ x 3 inches high, thus entirely overcoming the objections to the large size of former stamps. The printing is accomplished by a set of endless rubber bands which are automatically moved by an electrically operated impulse device at intervals of one minute. These rubber type bands are entirely new and represent all the tedious work of producing such articles accurate to $\frac{1}{10000}$ of an inch, something unheard of before in rubber manufacture.

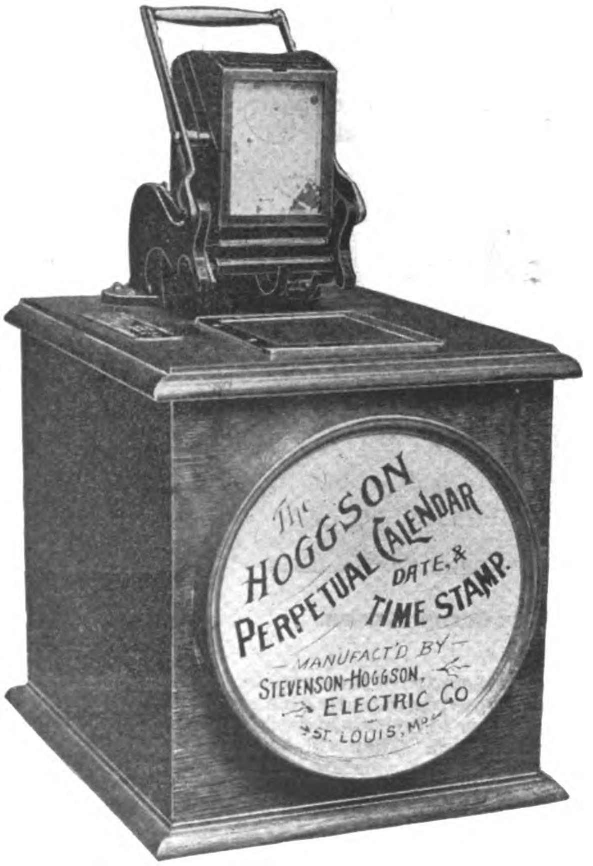


Fig. 1.—The Hoggson Perpetual Calendar, Date and Time Stamp.

By the aid of these bands the date and time complete can be printed clearly and distinctly in a space which can be covered by a silver quarter, and, being of rubber, as are also the dies, the impression is obtained by a gentle pressure. It will print nicely on uneven surfaces, such, for instance, as envelopes with inclosures, where metal die stamps signally fail. The machine will print readily any sized die up to 2 x 2⅛ inches, an impossibility with any metal-wheel stamp. The dies are interchangeable and can be removed and replaced instantly. Any number of dies can be used with a single machine. The stamp automatically changes the minutes and hours, and at 12 o'clock midnight, changes the day. It requires setting once a month to change the months and five times a year the day hand must be set to conform to the long and short day months. The changes are made with the same facility as setting a watch and take but an instant.

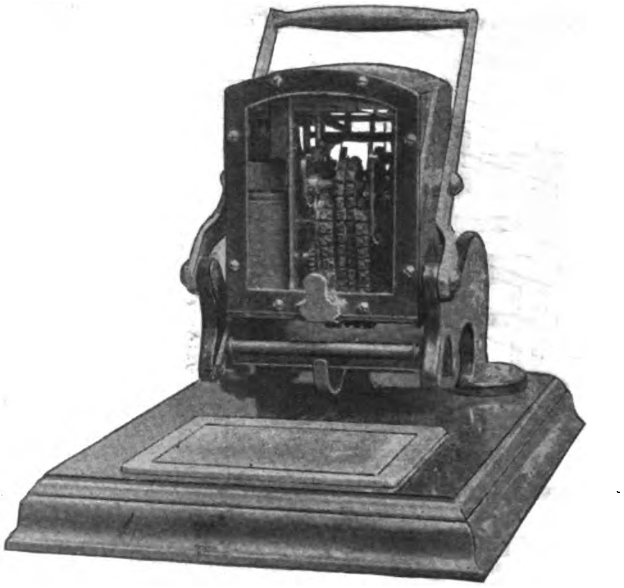

Fig. 2.—The Hoggson Perpetual Calendar, Date and Time Stamp.

As the machine stands before the user, it is not only a time-stamp but a perpetual calendar and time-piece, the dials on the face showing the month, day, hour and minute, correct time, and denoting the impression which the stamp will make at any instant, thus showing the operator at a glance whether the machine is running correctly, and just what it will print without taking an impression, thus avoiding any possible error.

These machines will run with two cells of battery and are also constructed to operate upon an open or closed circuit with either batteries, direct or alternating current lighting circuits, or storage batteries; in fact on any system containing sufficient power to ring an electric bell; and can also be run on any electric time or signal circuit. All the stamps in one building, block or entire city, may, if desired, be operated by one master clock. No special clock is required, it simply being desirable to have a correct time-piece, as the machine would otherwise record the errors of the clock.

All portions of these machines are manufactured on the interchangeable system, are as accurate as watch or clock work, and are not complicated or liable to disarrangement.

These time stamps are patented in all parts of the world and are manufactured by the Stevenson-Hoggson Electric Company, 919 Olive street, St. Louis, Mo.

A. J. VENEMAN.

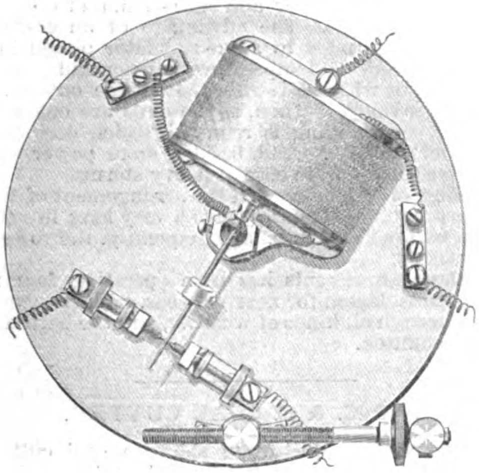
Mr. A. J. Veneman has just started a construction and supply business at 326 Main street, Evansville, Ind. His concern will carry a complete line of electrical supplies and will increase its stock as demand justifies. It will also contract for construction work of all kinds and install isolated and central station plants. Mr. E. L. Masters has been in the electrical business for about ten years; for the past three years he has held the position of superintendent of construction with the Evansville Gas & Electric Light Co. Mr. A. J. Veneman has also been connected with the same local company for about four years, but for the past year was with the Electrical Supply Co., Chicago, which experience has enabled him to attain a thorough knowledge of electrical supplies of every description.

THE MONTREAL CONVENTION.

Mr. A. J. Corriveau has issued a very pretty and interesting souvenir of the meeting of the National Electric Light Association at Montreal last September. It is well illustrated with portraits, landscapes, glimpses of the electrical exhibition, etc. All who were at Montreal will be glad to have it.

THE RITCHIE POTENTIAL INDICATOR.

It is essential to the successful working of an incandescent system that the pressure on the circuits should be maintained as nearly uniform as possible, and in order to do this in the most satisfactory way, a reliable pressure indicator is almost indispensable in an electric lighting station. To meet this requirement Messrs. E. S. Ritchie & Sons, of Brookline, Mass., have designed and perfected the instrument which is shown in the accompanying cut. The instrument is made in several different forms, though the principle by which it works is the same in each case. A coil about 3½ inches in diameter which holds the moving parts is mounted upon a slate base eight inches in diameter. This base supports and insulates the contacts and wire connections as shown in the cut. Where the instrument is exposed to dust it is found better to inclose the index-arm and contacts in a dust-proof case, and another form is made in which this is done and in which at the same time by removing a cap the contacts are at once exposed for adjustment when necessary. The base is held to the wall or switchboard by a bolt through its centre on which it turns by means of the long tangent screw. The adjustment of the instrument is very simple and easy and it will work practically without variation inside of one-half volt either above or below the voltage to which it may be adjusted and is singularly free from error due to vibration of building or switchboard. The instrument is kept constantly in circuit and the change in pressure is shown by red or green lights, as the variation is above or below the normal, the right pressure being attained when there is no light shown, thus avoiding the danger of running lamps above their normal candle-power. For house installation for electric lighting another form is made which is very cheap and satisfactory without the contacts and lamps, the pointer indicating on a graduated card simply high, right or low. It is claimed for this instrument that it is easy of adjustment, free from error due to vibration, and shows less error due to temperature, shows the change in the circuit pressure closely and quickly and is at the same time handsome and well made. These points have been determined after tests under the most severe conditions, extending over a period of many months in an electric lighting station where the instrument was left entirely in the hands of the superintendent of this branch of the electric lighting work.



The Ritchie Potential Indicator.

THE WESTON INSTRUMENTS ABROAD.

In a recently issued volume of the *Journal of the Institution of Electrical Engineers* of London, there appears an interesting discussion on a paper read in November last before the Institute, by Messrs. Sankey and Andersen, on the standard volt and ampère meters used in the establishment of Messrs. Willans and Robinson at Thames-Ditton. In the course of the discussion Mr. Evershed paid a high compliment to the good qualities of the apparatus of Mr. Edward Weston. He said:

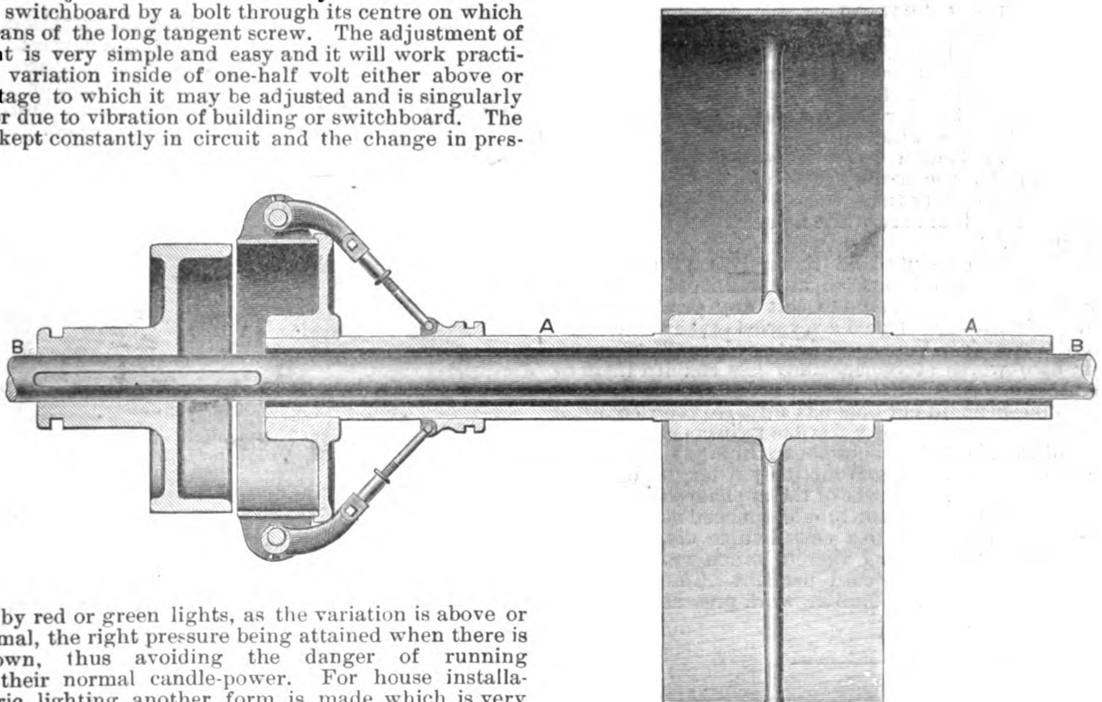
> "There is one species of d'Arsonval galvanometer which does not hail from France, nor is it an English copy of French instruments. It is made in America. We always assume that Americans cannot make instruments, and that may be true generally; but there is certainly one American who can, and that is Mr. Weston. His voltmeters are only d'Arsonval galvanometers in which the current is led in by two phosphor-bronze hair springs, which also act as the controlling force. Instead of the clumsy mirror and scale, a light aluminum index is fixed to the coil, and reads on the scale like an ordinary commercial instrument. The instrument I tested could be read to a quarter volt quite easily over the whole scale ranging from 0 to 150 volts, and I think that is quite comparable with the accuracy Captain Sankey mentions for readings with mirror and scale with d'Arsonval galvanometers in ordinary practice. Not only is the scale of the Weston instrument accurate, but the volts too are accurate. Mr. Weston calibrated this voltmeter in February last, and I tested it three weeks ago and found his volts agree with ours to .05 per cent. I think it is due to Mr. Weston to bring that to your notice."

We may remark parenthetically, that while Mr. Weston is an Englishman by birth, it is certain that what he knows about making instruments has been learned by him in America. It is gratifying to know that his patient, careful and thorough work in the line of measuring apparatus is becoming appreciated abroad as well as it is at home.

THE HUNTER FRICTION QUILL.

The accompanying illustration shows a form of shaft coupling adapted to places where heavy power is to be distributed on either side of a main driving pulley. As will be seen, the quill is supported on bearings at A A, and is entirely independent of the main shaft B B, except through the medium of the clutch. By this arrangement, there is absolutely no wear when the pulley is at rest, and, of course, no lubrication is required between the shaft and the quill.

An especial feature of the clutch is the use of two shippers, by means of which the drum may be withdrawn from under the friction bands, thus dispensing with oil when not in use. The grip of this clutch is claimed to be the strongest in existence.



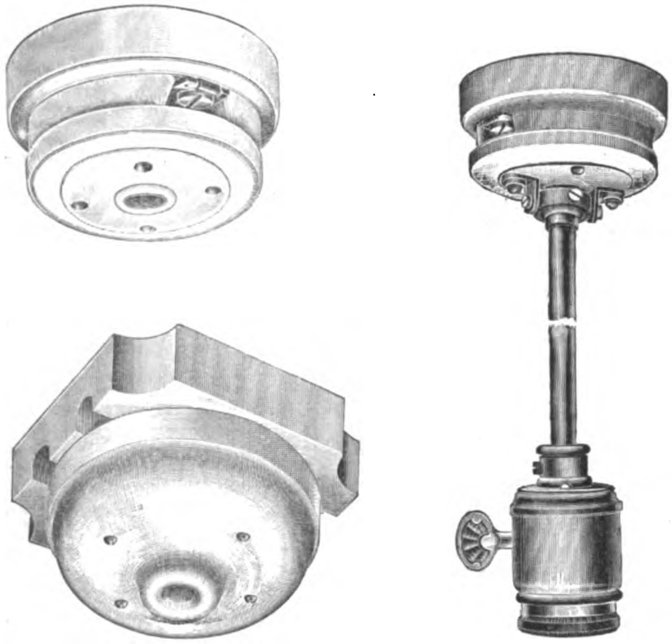
The Hunter Friction Quill.

The Hunter friction quill is manufactured by Messrs. H. N. Bates & Co., of 240 Congress street, Boston, whose New York office is at 126 Liberty street.

The Springfield Street Railway will equip eight miles of new line in the spring.

EDISON CEILING CUT-OUTS.

Recognizing the possibility of the increase in the demand for ceiling cut-outs the Edison General Electric Company designed and patented one some years ago, embodying many of the fundamental principles underlying all cut-outs devised for a similar purpose. Recently the old form of single-pole pendant cut-out was superseded by a double-pole cut-out of a novel shape, especially devised for cleat work and possessing additional recommendations and advantages, as shown in Fig. 1.



Figs. 1, 2 and 3.—Edison Ceiling Cut-Outs.

It is claimed that this cut-out can be sold as cheaply as the cheapest ceiling cut-out in the market, without depreciation of quality. This was followed shortly afterward by two new double pole cut-outs, one for moulded, and the other for concealed work. These are of special design and of superior workmanship to that mentioned above, their interior construction, however, being similar. The contact-pieces in the porcelain base are flat, and are provided at their terminals with small indentations which serve to catch and retain the bent contact-pieces in the cover and make a perfect contact. Two safety fuses protect the appliance. The cut-outs are made of the best hard white non-absorbent porcelain, and are shown in Fig. 2.

The two last named cut-outs lend themselves with peculiar facility to decoration. The Edison Company will shortly be ready to supply decorated ceiling cut-outs to suit any or all requirements. The designs already selected are varied and artistic. The establishment of a porcelain factory under their immediate supervision in their own works at Schenectady has enabled them to bring these cut-outs to a high state of perfection.

The use of ceiling pendant cut-outs has hitherto been confined to lights hung from the cut-out by a flexible twin conductor. The flattened shape of the No. 123 cut-out shown in Fig. 1, admits of use with a swinging light hung from it by a length of metal tubing. To effect this end, the cover of the appliance is provided with a universal joint, to which the tube is attached as shown in Fig. 3. The light can be swung to a considerable distance from its normal point of rest, returning thereto much more quickly than is the case with the flexible cord pendant. The many advantages for store lighting and similar work presented by this arrangement are obvious.

ELECTRIC HEATING.

A very interesting and handsome pamphlet on the subject of electric heating has been issued by the Burton Electric Co. through their selling agents, the Electric Merchandise Co., of Chicago, with reference to the celebrated Burton heaters. It gives views and descriptions of the apparatus as applied to street cars, and quotes a large number of testimonials from various electric roads using the system. It also includes three very interesting newspaper articles on the general subject, one being that which Mr. W. R. B. Willcox contributed to our columns some months ago, and which attracted no little attention.

A TOWER CLOCK OPERATED BY AN ELECTRIC MOTOR.

For some months the Standard Electric Time Company, of New Haven, Conn., have been making careful tests with a special electric motor driven by current from open circuit batteries, to operate tower clock dials. Few tower clocks are found to indicate correct time, but vary considerably unless constant attention is given them. This is partly on account of their being exposed to the extremes of temperature. Besides this, they must be wound up every week, which is no small "chore," and considerable sums are paid yearly for this labor and attention, and even then the clocks are seldom right. The advantage of an electric tower clock is that it is controlled by a fine regulator placed in a room in the building where the temperature is even and means are at hand for keeping it within a few seconds, at the outside, and the tower clock must follow. Then, as the dials are operated by an electric motor, no winding is required, which does away with much labor and expense. And, besides, more power can be delivered to drive the hands in case of heavy storms.

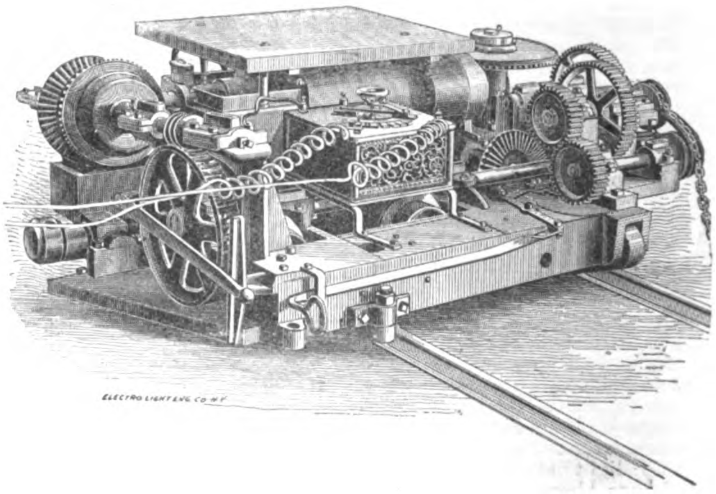
The winding of the motor and the arrangement of the power from it is such that the batteries have a very long life (from one to two years without renewal). Consequently, the tower seldom needs to be visited.

One of these movements has been operating four nine-foot dials at Lawrence, Mass., for nearly a year, and has given perfect satisfaction through all kinds of weather, and the batteries are yet in excellent condition.

THE C. & C. COAL CUTTER.

The accompanying illustration shows a coal cutter of the undercutting type driven by a 15 h. p. C. & C. electric motor of special design, in operation in the Mead Run Mine in Pennsylvania. The motor, placed in position on the machine, is covered by a heavy board which serves to protect it from possible injury. The starting box is also placed on the machine in a convenient position, as can be seen from the illustration. The armature shaft carries a beveled pinion at each end, and, by a mechanical device, this can be made to operate the endless chain to which the coal-cutting knives are attached and which revolves about the arm, and also to operate the feed chain which is made fast at one end, so that the machine can be moved forward at any desired speed, or allowed to remain stationary if the hardness of the coal so requires. The potential of the electric motor being low, 220 volts, there is no danger to be feared from coming in contact with the wires.

The knives used for cutting are of the greatest durability, and, when dulled, can readily be replaced by a new set. By using this style of machine the necessity and inconvenience of moving by hand in a low room is avoided, and the track on which it travels is such that it can be easily laid or moved as desired. Two men operate the cutter, one regulating the speed of the gears and the other attending to the moving of the machine.



The C. & C. Coal Cutter.

The Thomson-Houston Electric Co. have found this machine so successful in mines where an undercutting machine can be used to advantage that they have made an arrangement for its adoption, and it is expected that several mining machinery manufacturers will do the same.

Schleicher, Schumm & Co., manufacturers of the Otto gas engine, have opened an office and salesroom at 19 Pearl St., Boston, Mass.

WESTERN NOTES.

Mr. C. E. Sargent, manager of the Chicago office of Messrs. A. L. Ide & Son, has received the following orders for Ideal engines since the beginning of the year: E. W. Blatchford, one 55 h. p. for incandescent lighting; Winslow Bros., one 35 h. p. for electroplating; the Sperry Electric Mining Machine Co., one 100 h. p. for an electric haulage and mining plant; Groveland Apartment Building Co., one 35 h. p. and one 55 h. p. for incandescent lighting; Hyde Park Electric Light and Power Co., one 250 h. p. tandem compound for arc lighting; Thomson-Houston Electric Co., two 125 h. p. engines and a complete plant for an electric railway; the National Electric Mfg. Co., two 100 h. p. for an alternating incandescent plant; and the Bavarian Brewing Co. one 85 h. p. During the past week, two 80 h. p. Ideals have been placed in the Unity Building for incandescent lighting; three 100 h. p. Ideals in the Ashland block for incandescent lighting; one 100 h. p. in the Arc Light and Power Co.'s Market street station; one 55 h. p. in J. S. McDonald & Co.'s new factory for incandescent lighting, and one 100 h. p. and one 150 h. p. in the Grant Locomotive Works for lighting and furnishing power for three electric cranes.

The Great Western Electric Supply Company, Nos. 201 to 207 S. Canal street, report a most gratifying increase in the demand for their electrical goods, especially their Sun arc lamp, which can be used singly or in series and gives a most beautiful, steady, white light. They are also receiving large orders for a new focusing arc lamp, several of which are in use in various parts of the city. There is also an ever-increasing demand for their celebrated K. K. wire. They are doing a large business in house-goods supplies, and the sales are increasing daily. The fixture department reports very large sales in Missouri, Louisiana and Illinois. The business of this year compared with last shows a big gain, while the outlook for 1892 is better than it was this time last year.

H. T. Paiste's Western Office.—Mr. Paiste is well known to the electrical fraternity as a pioneer in the application of beauty and art of invention. The artistic appearance of his Western office at once strikes the visitor as he enters. The display of china switches, both in a handsome showcase and upon a neat sample board, gives evidence of the art of decorating, of which Mr. Paiste is the master. The unique method of advertising his china switches by well-executed outline drawings of Chinamen well deserves special notice, and we understand that central station men and purchasers will have the pleasure of seeing Paiste's Chinaman figuring in the advertising columns in the near future.

Camden, Ark.—The electric light plant of the Camden Electric Light and Power Co., Camden, Ark., was seriously damaged by fire on January 24th. Steps were immediately taken, however, to resume operation, and it was decided to equip a new and independent plant. Formerly the steam was secured from the water-works boilers, but the company will now put in its own steam plant, having ordered two 60 inch x 16-foot boilers, and a No. 7 Hoppes exhaust heater, from the Pond Engineering Company, through its Dallas, Tex., office. The engines, while considerably damaged, can be repaired.

Mr. A. H. Englund, formerly secretary and treasurer of the Electric Merchandise Co., Chicago, has opened an office at 435 "The Rookery," as secretary and manager of the International Register Co. This company have purchased the Pratt patents on conductors' fare registers and have equipped a very complete factory for the manufacturing of these machines in both portable and stationary forms. Mr. Englund's long and practical experience in the street railway supply trade has made him a host of friends and the success of his new enterprise is assured.

The Electric Appliance Company are introducing something in the line of a combination branch block. As at present constructed the block is adapted for eight circuits, although other sizes are in course of construction. It is about 8 x 12 inches, made of hard porcelain, with highly-polished oak or cherry cover. This block can be placed on the wall or in other suitable places, requires but very little space and when connections have been made the cover is fastened on by screws, making a very neat and substantial job.

The Electrical Appliance Company have completed arrangements to represent the Cutter Electrical Specialty Company of Philadelphia in the West, and will hereafter carry a full line of the Cutter portables, reflectors, flexible brackets, etc., for which a very large demand has already been established. To those familiar with the Cutter specialties, it is not necessary to state that they are a line of very desirable articles.

The Electric Appliance Company report having just closed arrangements with the Ries Electric Specialty Company to control the sale of their socket in certain Western territory, and are making active preparations to thoroughly introduce this valuable specialty. They will carry a large stock on hand in Chicago at all times.

W. B. Pearson & Co. have just closed a contract for complete steam plant for the city of St. Charles, Ill., who are installing a lighting plant. The engine furnished is one of 80 h. p. Ball & Wood single cylinder. This deal was closed by Mr. H. E. Jefferson for his company, and his bid was the highest. It reflects great credit on his abilities in convincing people that they must have Ball & Wood engines.

The Electric Merchandise Company are doing a very large business, especially in the East in electric street railway supplies, which they deal in exclusively. Mr. W. R. Mason reports a very brisk demand for Burton electric heaters for car service from all parts of the country, and says that electric heating is now acknowledged to be the ideal in every respect.

Mr. Chas. E. Wilson, widely known throughout the West among central station and street railway men, has accepted a position with the Electric Merchandise Company as general traveling representative. Both Mr. Wilson and the Electric Merchandise Company are to be congratulated on this connection.

The belts for the new Leiter Building, comprising two 48-inch main belts and ten 14-inch dynamo belts, were furnished by the Chas Munson Belting Company, who thus have the distinction of belting up the largest isolated plant in the city. This order was secured in the face of the keenest competition.

The Chubbuck Malleable Iron Brackets still continue to hold popular favor and are used by nearly every company in the country. They are far superior to cast iron, being both lighter and stronger. The Great Western Electric Supply Co., Chicago, are general agents for these goods.

The Central Electric Company in preparation for the coming spring business have laid in a large stock of all classes of supplies, such as hard rubber tubing, Banner weatherproof wire, Bryant sockets, switches and cut-outs, expanding wire guards, Swan lamps and Washington carbons.

The Electrical Supply Co. are receiving numerous orders for their favorite specialties, comprising Sunbeam lamps, Shield brand line wire, Stanley transformers and Habirshaw rubber-covered wires and cables. In general electrical supplies of all kinds the demand is very brisk.

Mr. George McKinlock, of the Central Electric Company, says that his company are experiencing an excellent activity in general supplies and a very brisk demand for specialties, and Okonite is as usual keeping up its record.

The Central Electric Company report being well equipped to handle all orders for carbons of all the standard sizes, having a large stock of molded, both plain and coated, made by the Washington Carbon Company, for whom they are general Western agents.

The Ernest L. Clark Company, of 540 The Rookery Building, report a large and increasing trade in all kinds of iron and cedar poles. In Dubuque, Iowa, alone, they have closed contracts amounting to 30 car loads of metal in the past week.

Mr. F. E. Drake has accepted an appointment as district manager of the Rockford Electric Mfg. Co. of Rockford, Ill., with headquarters at No. 451 Rookery, Chicago, Ill.

The Electrical Supply Co. are furnishing a great many Stanley transformers, which are giving very excellent results.

HUDSON RIVER NOTES.

Hudson, N. Y.—The Hudson Electric Railway has been contemplating the extension of its lines to Fillmont, a distance of nine miles, but the recent law of the Legislature forbidding an excess of five cents being charged for fare will prevent such a move at present. Probably few roads can show, like the Hudson, a net profit of 57 per cent. above operating expenses. Their four cars have made an average of 117 miles a day for a year and a half without the loss of an armature or field. The motorman has the entire charge of a car while the trolley looks out for itself, and seldom makes an attempt to get off the wire. The managers think that this method makes the motorman more careful about entering switches and turnouts and is thus much easier on the machinery.

Troy and Lansingburgh Railroad Officials have been looking over the ground and inspecting Broadway and Union streets for the purpose of locating the tracks to form the new loop to the depot, and as soon as the weather will permit the work will begin, and be pushed to completion as rapidly as possible. It is stated that it will entail considerable study to arrange the schedule so as to accommodate passengers from both ends of the line and at the same time suit the requirements of the company. During the coming summer work will be pushed on all the contemplated branches, but the depot loop is considered of the most importance at present, and will be taken in hand first.

NEW YORK NOTES.

H. Ward Leonard's method of electric motor control, which he exhibited for the first time at the Montreal Convention and upon which he has recently secured broad patents, has met with great favor at the hands of the electric elevator people. Mr. Leonard has granted licenses to the Otis, Crane, Hale, Stokes and Parrish and Whittier Elevator Companies, and electric elevators operated under Mr. Leonard's method are being rapidly introduced by these companies. This elevator is popular with the central station managers, as it uses so small a current in starting up the elevator as to have no effect upon electric lights on the same circuit. By Mr. Leonard's method an electric elevator can be operated from an Edison three-wire circuit, an arc circuit, a railway circuit or an alternating circuit, which gives it an exceptional flexibility. The capital of H. Ward Leonard & Co. has recently been doubled and the increase taken by gentlemen prominent in the leading railway, banking and gas interests of New York City.

The Interior Conduit and Insulation Co. have issued a new set of specifications for wiring for electric light, employing their conduit system. It is very complete in its provisions, and if lived up to by those who do the work should ensure a most satisfactory and perfect installation. The details of the interior conduit system have been so carefully worked out that the company believe it leaves no opportunity for just criticism but meets all requirements. The Interior Conduit Co. make the point however that their system of wiring should be used in its entirety, and that contractors should follow these rules to the letter.

Emil Gabel & Co.—This is a new concern established by Mr. Emil Gabel, a veteran belting man. It will be sole Eastern agent for the celebrated "Monarch Rivetless" and "Bradford Dynamo" leather belting, and will carry also a line of lace leather and general mill supplies. It will have a temporary office at 96 Centre street, but after May 1 will be installed at 44 Dey street. A circular issued by the firm contains two testimonials as to the Bradford belts, from the Brush plant at Cincinnati and the Brighton, O., electric railway station.

The Dreher Manufacturing Co. of 37 Platt street, this city, are introducing a very fine grade of specially refined lubricating oils, which should prove valuable to those who have dynamos and other high-grade machinery in their charge. They are moreover making an oil for dynamo use exclusively, which is the result of many months' of experimenting and compounding. The company employ a corps of analytical chemists in their work, and guarantee their oils as in every way of the highest and best class.

The Electric Merchandise Company, of Chicago, is making considerable of an Eastern "hit" for a Western concern. But it is an active progressive house and has invaded every State. Many new roads are specifying its overhead fixtures, whatever system they adopt, which is the best sort of a testimonial. All speak well of the company and its equipment. Already, it is unexpectedly busy with a new season's business.

Mr. W. W. Nugent, a consulting and contracting engineer of prominence, has been appointed the sole agent for the celebrated Goubert water-tube feed-water heaters, vertical and horizontal, in Chicago, his office being located at 823 Home Insurance Building, that city. The Goubert Manufacturing Company find a demand for their heaters, which is keeping them busy at their New York headquarters, 32 Cortlandt street.

T. J. Murphy, maker of slate switchboards, says that by marbleizing the slate, the moisture resisting qualities are greatly increased He also suggests the application of a coat of paint on the back of the board after all the boring is finished. By doing this the holes are saturated, and when the instruments are assembled thereon the entire surface is practically moisture proof.

Mr. W. C. McIntire has resigned as manager of the New York office of the Eddy Electric Manufacturing Co., owing to the demand made upon his time by his personal affairs in Philadelphia. He is now removing his offices permanently to the latter city, and will handle the motor there and for the South. Mr. F. C. Ross succeeds him in charge of the New York office.

Mr. Unico H. W. Schenck has become the New York agent for the American Leather Link Belt Co., whose principal offices are at 46 and 48 Ferry street, and who are now the sole manufacturers of the American joint leather link belting, which they guarantee for hard work of all kinds.

Mr. E. L. Burrell, manager of the Western office of the Chas. A. Schieren Belting Co., who spent a few days in New York after the close of the convention at Buffalo, has returned to Chicago. He was able to report an excellent trade and the outlook most promising.

The American Manufacturing and Engineering Company have removed from 15 Cortlandt street to Central Building, 143 Liberty street, opposite the Pennsylvania and New Jersey Central and Baltimore and Ohio Railroads.

PHILADELPHIA NOTES.

Warren Webster & Co., 491 N. 3d street, Philadelphia, Pa., are the sole licensees of the Williams vacuum system of steam heating whereby they guarantee to heat buildings without back pressure upon engines, and increase the efficiency of the heating surface. They put the system in on trial, and during the past few weeks have booked orders from the following firms: Windsor Folding Bed Company, Chicago, Ill.; Hawley & Hooper, confectioners, Mulberry street, New York; W. L. Kann & Co., Pittsburgh, Pa; Journal Building, Jersey City, N. J., through W. W. Farrier, steam heating contractor, Jersey City, N. J.; Joliet Enterprise Company, Joliet, Ill.: Simson Nickel Manufacturing Company, Wallingford, Conn.; N. C. Penitentiary, Raleigh, N. C.; Wood, Jenks & Co, Cleveland, O.; Insane Asylum, Raleigh, N C.; The Cooper Hospital, Camden, N. J.; Cramer Company, Norfolk, Va.; Robert Gair, Manufacturing Stationer, Brooklyn, N. Y.; Eckington and Soldiers' Home Railway Company, Washington, D. C.; Pencoyd Iron Company, Pencoyd, Pa.; Elba Iron Company, Pittsburgh, Pa.; Krann & Bro., Philadelphia, Pa.; Baltimore and Potomac R. R. Station, Washington, D. C.; H. P. Nail Company, Cleveland, O.

Mr. Chas E White, formerly sup't of the Pottstown Electric Light, Heat & Power Co., has accepted the position of salesman for Otis K. Stuart, who is manager for the Germania Electric Co. for the Southeastern district.

Mr. Otis K. Stuart has secured the agency for John O. Heinze & Co., of Lynn, Mass. The firm manufacture electrical measuring instruments, Wimshurst machines, induction apparatus and a general line of experimental electrical appliances. Mr. Stuart will be general selling agent for these goods and parties interested should communicate with him.

W. H. Weston & Co., manufacturers of electrical appliances, etc., are now at work on a new illustrated price list which will be ready to distribute about March 20. This enterprising firm report business brisk, with some night work.

The Pennsylvania Electric Engineering Co. has just been awarded the contract for furnishing the electrical department of the city of Philadelphia with supplies for the year ending March 1, 1893.

ST. LOUIS NOTES.

The Emerson Electric Manufacturing Co. have just issued their first annual catalogue which is a well-arranged pamphlet of eighty pages. As a frontispiece are given two excellent photo-engravings, one representing the feeder switchboard of the Lindell railway power plant, and the other the switchboard of the lighting plant of the Cupples Building, both of which are models of simplicity in design and excellence in construction. Following the title page is given an introductory and special advice to purchasers, after which follows the catalogue proper, which is divided into six divisions—appliances for electric lighting, appliances for electric railways and power plants, electric railway line supplies, alternating current motors, special apparatus, and the engineering department—in which appear the names of E. J. Bagnall and A. W. Meston as consulting electrical and mechanical engineers.

The Emerson Electric Manufacturing Co. have increased their capital stock to $75,000 and elected the following officers: J. W. Emerson, president; C. R. Meston, secretary; A. W. Meston, superintendant. The business of the company has increased steadily throughout the year, so much so that they were compelled to seek larger quarters last fall. In their new quarters at 1110 and 1112 St. Charles street, they have ample room and facilities to handle their largely increasing business. Their new catalogue will be issued shortly.

The Stagl Engineering Co. has removed to 408 North Eighth street. They have been kept pretty busy during the past few months. One of their recent orders is for a 200-light incandescent plant for the American Brewing Co., of St. Louis, and another is for an 8 h. p. motor for the hard lumber firm of Smith & Little, in North St. Louis. The dynamo and motor in these plants are of the Card Electric Motor Co.'s make and are giving full satisfaction. The Stagl Company are also busy wiring a number of new buildings.

J. H. Siegrist, Jr., & Co., St. Louis, have recently sold Bristol recording pressure gauges to the Springfield, Ill., Electric Light and Power Co.; two to the Ottumwa, Iowa, Electric Railway Co., and one to the Central Distillery Co., of this city.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XIII. MARCH 23, 1892. No. 203.

THE ELECTRICAL TRANSMISSION POWER PLANT AT THE CHICAGO WORLD'S FAIR GROUNDS.

BY

H Norman Collins.

I.

EVIDENCES that electricity as a means of transmitting power is becoming the prime favorite are more numerous every day. On all sides large factories, mills and other manufacturing establishments are adopting the ever-ready motor to perform their various work, and discarding the long lines of shafting with its complex arrangements of belts and pulleys. One of the largest engine and mining machinery manufacturing companies in the world has recently equipped its new factory entirely with electric motors on account of their great economy, reliability and safety. In town and cities all over the country the power load of the central stations keeps steadily creeping up and is becoming a more and more important factor in economical operation, and the sub-title of "Power" which but a short time ago was merely a sign, now possesses an exceedingly positive meaning. It is for these reasons that the engineers of the Construction Department of the World's Fair determined from the first, that the power required for building the Exposition structures and performing all labor connected therewith should be entirely furnished by means of electricity, as being the most modern and perfect agent to perform the work expeditiously and economically.

It has been the good fortune of the writer to examine carefully the plant in all its details of generating and receiving machinery and watch the various electrically-driven devices in operation, and observe with what great reliability they do their work in this large and scattered plant. It is thought that a description, together with illustrations of some of the various apparatus employed in carrying out the great work will not be without interest, as although this plant is of a temporary nature, and intended to be dispensed with before the opening of the Exposition, it has been erected and carried out with the greatest care, and embraces the best and latest methods of construction. It represents, in short, a very perfect electrical power transmission plant, and one in which the conditions are of a somewhat peculiar nature by reason of the long distances between the apparatus, and because this apparatus is being continually moved from place to place wherever it may be required to do any particular kind of work. For this reason the plant had to be built with lines extending in such a manner as to enable the power to be furnished at any building and all parts of the grounds.

II.

The first points that strike the observer in looking over such a task as the one under consideration, are the advantages to be gained by using electricity. The principal machinery to be driven for the construction of the buildings, which are made of wood and covered with staff, giving them the appearance of massive marble structures, are saw-mills for cutting lumber, and hoists for raising the iron and steel trusses, girders and heavy beams. In addition to these machines, pulverizing machines for molding clay are required and planers for shaping lumber. The principal advantage of operating the saw-mills by electric motors is absolute safety from fire, which is of the very greatest importance, on account of the great quantity of inflammable material around the mills. When portable engines and boilers are used, in which the waste wood is burned as fuel, there is a great liability from flying sparks igniting the surrounding shavings and sawdust. In saw-mills, on a large scale, electric power is used with a very considerable saving in attendance, as it is furnished to the contractors at any hour of the day or night whenever they may require it. Another item is the great convenience gained when it is desired to start and stop the machinery at frequent short intervals. In a temporary plant of this kind this feature is exceedingly advantageous from many points of view. Supposing a case in which a contractor is

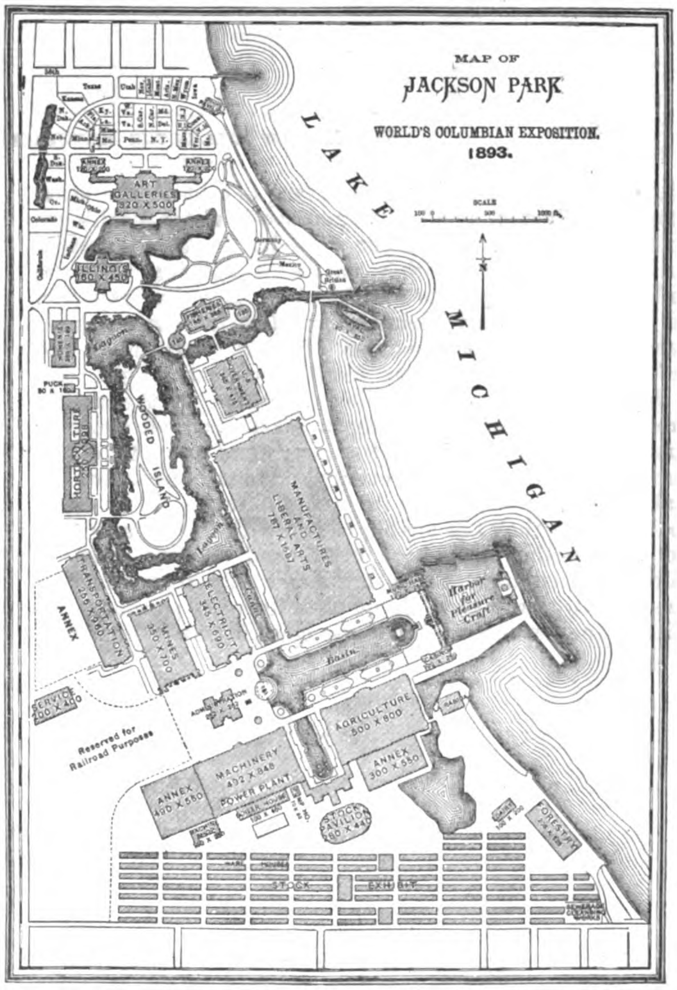


FIG 1.—THE AREA COVERED BY ELECTRICAL POWER PLANT, WORLD'S FAIR, CHICAGO.

running his saw-mill all day to-day and having cut out all the lumber he considers necessary, shuts down to-morrow, and then finds that while shut down he requires a few pieces of certain dimensions his motor is all ready for immediate service, and he is not compelled to keep his boiler fired up all the time. In operating saw-mills in general, there are always a number of tramways for conveying and hauling lumber and these can be more readily and better operated by electricity than any other means of power, and in most cases electric lighting is also used for the illumination of the mill and tramways, and a large saving in cost of operation is thereby effected, as all large and successful saw-mills are run day and night. The light given by electric illumination is so superior to other modes of lighting, that the lumber can be cut just as well by night as in the daytime, and in fact some enthusiastically electric sawyers have even had the hardihood to claim that they can detect imperfections in lumber more readily by electric light than by daylight. Where saw-mills are located in the neighborhood of waterfalls having a good head all the year round, as is very frequently the case, great advantages are attained by using electrical energy. Where wood-working establishments are situated in saw-mill towns, it is often the case that they are unable to run with their waste products, unless they use a high grade and efficient class of boilers and engines, which are necessarily expensive, and even in many cases they would then have to purchase additional fuel, whereas if they use electric power furnished from water, a very distinct saving in their running cost is effected.

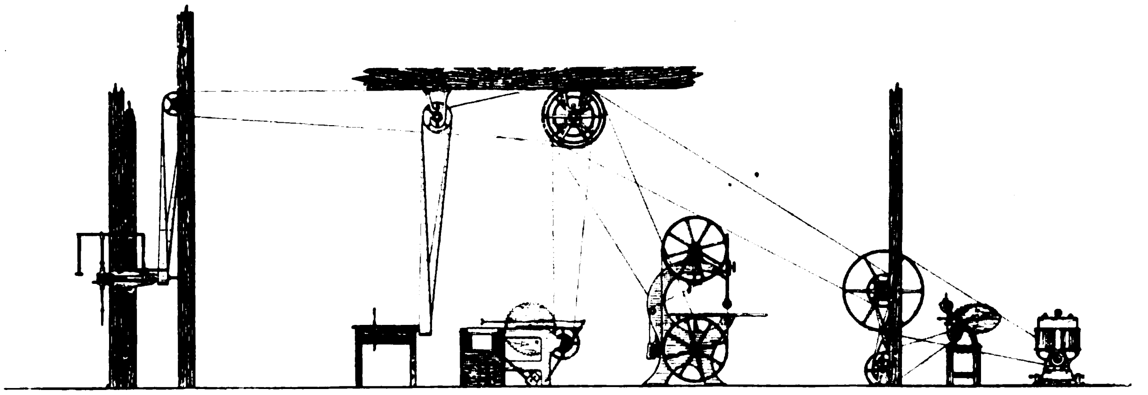

Fig. 2.—Saw Mill in the Manufactures and Liberal Arts Building.

The operation of hoists by means of electricity has some apparent advantages, and on the grounds of the Exposition the same features of safety and minimum amount of attendance as in the electrical operation of the saw-mills are very prominent. In this case particularly there is a great convenience and saving in fuel, as there is no necessity of keeping a boiler fired up all the time, and the economy is even considerably greater than in the case of the saw-mills, as a hoist is often left idle for several hours and then run possibly for but a few minutes, as the work is of a very intermittent character. Electric hoists are lighter and more compact, and therefore better adapted for transportation and uses in odd places, and they perform their work in a better and simpler manner, as they are more easily controlled.

III.

The prime consideration is the generating plant, furnishing the current for the motors; and its appurtenances of poles and wires for distributing the power. The plant at the Exposition grounds consists of two 100 K. W. compound-wound Edison generators similar to those used in their street railway work. These machines are run by two high speed engines belted direct, at such a speed as to give an average E. M. F. of 500 volts. The plant is thus divided into two distinct units, either one of which is capable of taking care of the entire load for a temporary period, reducing the chances of a total break-down to a minimum. It is a well-known fact that it is almost an impossibility to have all the motors running at once; and further, the machines are capable of taking care of a considerable overload for a short space of time. These machines are located in the "temporary" lighting station, which, by the way, does not have a very temporary look about it, it being built as solidly and laid out as neatly as many a permanent city station. The temporary pole line carrying the power conductors, makes a complete circuit of that portion of the grounds on which the Exposition buildings are located, so that the service can be tapped for use in any part of the buildings, or connections be made to any point in the grounds within a few hours at the most. This line, like the generator station, although only of a temporary nature, is of first-class construction, the best of material being used throughout, and a high insulation of the wires is maintained at all times, every circuit being subjected to constant rigid inspection and daily tests made of every part

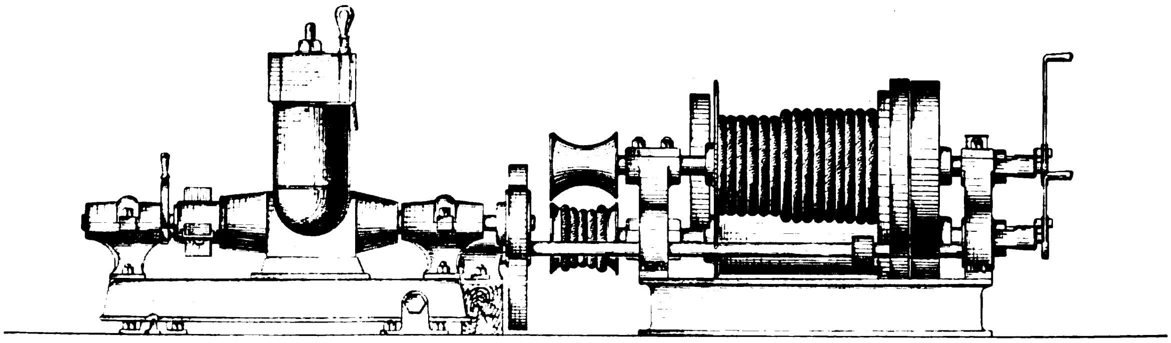

Fig. 3.—Electric Hoist in the Horticultural Building.

while in operation. The plan shown in our illustration, Fig. 1, is the latest one, of the various improvements in Jackson Park and shows the location of all the buildings, and their various dimensions and it can be seen at a glance where the building in which any of the machinery described, is being operated.

It may be stated here that no overhead wires will be used during the Exhibition, as a comprehensive system of underground subways is now being built and is well under way, in which the wires and cables for supplying all sections of the buildings and grounds with light and motive power will be placed.

IV.

In the description of the several machines run by electric power it has not been deemed necessary to enter into any very minute details of the construction, either of the motors or the saw mills and hoists, as most readers are familiar with the very simple mechanical working of these devices.

In Fig. 2 is shown one of the saw-mill plants which is in operation in the Manufactures and Liberal Arts Building, which it will be noticed is the largest structure of the Exposition, measuring 1,687 x 787 feet, and covering an area of more than thirty acres in a most conspicuous portion of the grounds, thus being the largest building for exhibition purposes ever constructed. This mill is run by a 12 K. W. Edison shunt-wound motor which is belted to a line shaft, the line shaft being belted to a counter-shaft which runs the saw sharpener, and also to another overhead counter-shaft running a band and cut-off saw, and by means of other counter-shafts, running a rip-saw and boring machine. This is a very compact and simple outfit, and like all the rest of the plant does its work reliably and well.

In the United States Government Building which is situated near the lake shore to the south of the main lagoon and is an exceedingly handsome and imposing structure, another saw-mill plant is at work. A 15 K. W. Edison shunt-wound motor is belted to a line shaft beneath the floor level, which carries pulleys belted to cut-off, rip-saw and boring machines. The leading architectural feature of this building is a central octagonal dome 120 feet in diameter and 150 feet high.

Another saw-mill plant, is in use in the Mines and Mining Building, in which it is interesting to note that the cantilever system as applied to roofs is used, and which is the only building, excepting the large domes, that has steel roof trusses. A 15 h. p. shunt-wound Sprague motor was doing the work here at the time of making the drawings, but a 6 K. W. Edison motor has now been substituted for it. The motor is belted to a counter-shaft carrying a pulley which runs a rip-saw and grindstone. A somewhat similar saw-mill plant is located in the "Horticultural Building." An 8½ K. W. Edison shunt-wound motor belted direct to a line shaft, running cut-off saw, grindstone and boring machine, and a rip-saw by means of a separate counter-shaft, is here to be seen at work. The "Horticultural Building" is also equipped with an electric hoist of which the accompanying cut, Fig. 3, gives a very complete idea. The motor, which is a 20 K. W. shunt-wound Edison, is mounted upon the same frame-work as the bed-plate of the hoist, and geared to it by means of a rawhide pinion on the motor shaft and a gear attached to the main shaft of the hoist. The bed-plate is made to receive a steam engine and boiler. This precaution was taken in order that this hoist could be used after finishing its work at the Exposition, in places where electric power was not obtainable. The hoist is of the ordinary double-drum form, with two winch heads. It is a very convenient machine, as it can raise two weights, or two parts of the same weight; while at the same time the winch heads can be used to drag material into position. The motor is run at a uniform speed, but the speed of the drums can be doubled by throwing in a back gear arrangement, and any further variations of speed desired can be obtained by means of the winch heads. This hoist is used for lifting the large trusses and purlins of the Horticultural dome, and is found to be equal to every demand upon it and can be controlled with the greatest ease.

Fig. 4 shows a similar electric hoist operated by a 20 K. W. Edison shunt-wound motor and which is in use in the Transportation Building, lifting the main trusses and purlins used in its construction. The hoist is mounted on the same base as the derrick, which is movable upon rollers in order to place it in any desired position. The motor is attached by a single set of gearing to the hoist in a similar manner to Fig. 3. This, together with the former cut, shows the details and construction of the hoist apparatus very clearly. This hoist has, since the date of writing, been removed to the Agricultural Building, where it is now in use.

The Transportation Building is also furnished with a saw-mill which is operated by a 12 K. W. Edison shunt-wound motor driving cut-off, rip, band saws and grindstone. The motor belts to a line shaft, which in turn runs the various mechanisms.

A large saw-mill plant, Fig. 5, is located in the Agricultural Building. A 20 h. p. Sprague motor is belted to an overhead line shaft which runs the boring machine, band saw and cut-off saw. From this line a counter-shaft running a rip-saw is driven.

V.

The Electricity Building is also equipped with a saw-mill plant. The dimensions of this building as given in the latest map are 349 x 680 feet, and a few further details may not be out of place here. The south front of the building is on the large court and the north towards the lagoon. The general plan of the building is a longitudinal nave 115 feet wide and 114 feet high, crossed in the middle by a transept of similar dimensions. The second story comprises a series of galleries connected across the nave by two bridges and accessible by four grand staircases. The exterior walls of the building are composed of a continuous Corinthian order of pilasters 42 feet high, supporting a full entablature, and resting upon a stylobate

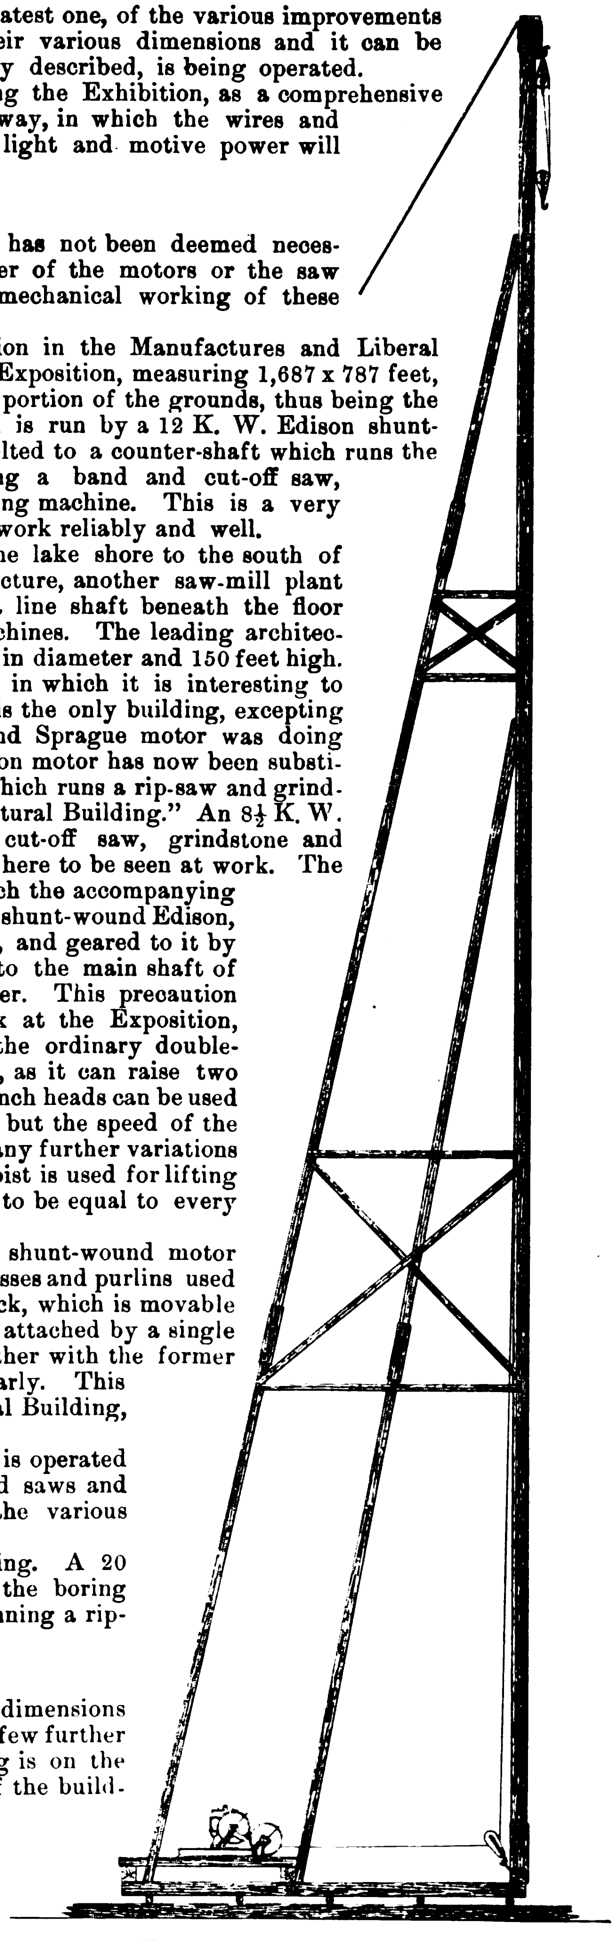

Fig. 4.—Hoist in the Transportation Building.

of 8 feet 6 inches. The total height of the walls from the grade outside is 68 feet 6 inches. Each of the four corners has a pavilion, above which rises a light open tower, 169 feet high. Intermediate between these corner pavilions and the central pavilions on the east and west sides, there is a subordinate pavilion bearing a low, square dome. In the design of this building the architects have endeavored to so devise its details and general outlines that an electrical illumination by night can be provided which in effect will be unequaled, even the flag-staffs, open porticos and towers being arranged with this end in view. The illustration Fig. 6 shows a plant which is run by a 12 K. W. Edison shunt-wound motor belted to a shaft from which run other belts to band and rip saws, gearing being used to run the cut-off saw.

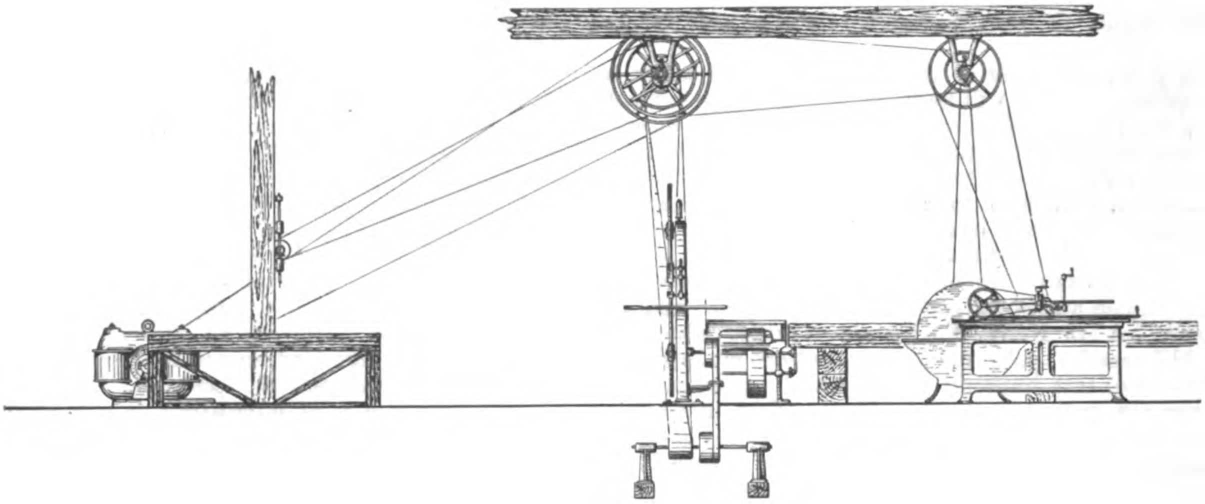

FIG. 5.—SAW MILL IN THE AGRICULTURAL BUILDING.

Fig. 7 illustrates an electrically operated automatic pulverizer made by Raymond Bros. This pulverizer is run by a 12 K. W. Edison shunt-wound motor which is belted direct, driving it at a speed of 1,200 r. p. m. This machine is used in molding clay for crushing purposes and other work of that class.

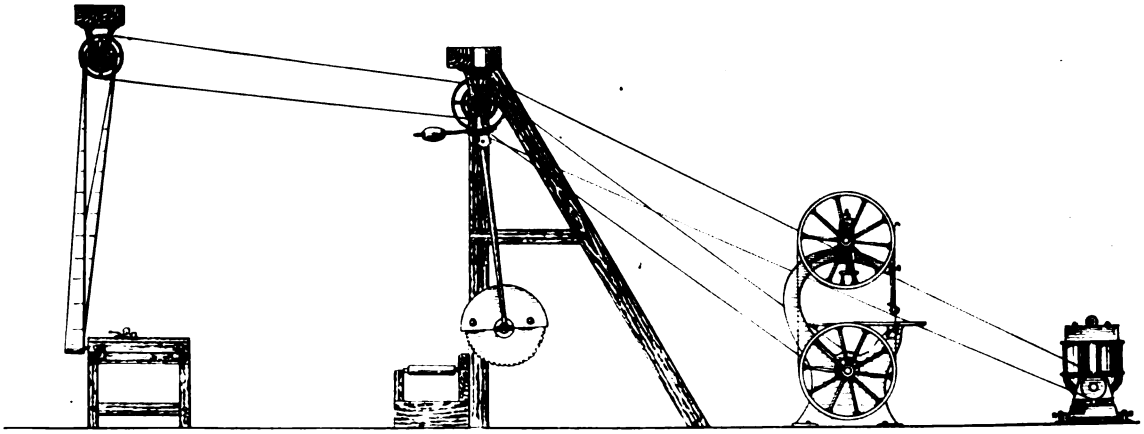

FIG. 6.—SAW MILL IN THE ELECTRICITY BUILDING.

In the Machinery Hall is placed a saw-mill as shown in Fig. 8. This is run by a 25 h. p. Sprague motor, which is belted to a shaft running beneath the floor from which driving belts run to a cut-off, rip-saw, boring machine and grindstone. Another saw-mill plant is situated in the Illinois State Building. An Edison 15 K. W. shunt-wound motor drives this mill, being belted to a line shaft which drives a rip and table cut-off saw, also running by means of two counter shafts a cross-cut saw. There has also been installed in this building a 6½ K. W. Edison Standard electric hoist which has recently been received. This is of the single-drum pattern and similar in every respect to their electric hoists of which so many are doing excellent work in all parts of the country.

VI.

In addition to the several plants shown in our illustrations, a saw-mill plant similar to the above has just been placed in the Fisheries Building, a 20 K. W. Edison motor operating a band, rip and cut-off saw. A 6½ K. W. electric motor operating a planer has also just been placed in the Women's Building.

All the motors running the various plants are operated by means of an ordinary starting switch and rheostat, and main line switches in series with each motor; approved fusible cut-out arrangements being used in every case.

Each motor is housed to protect it from dust, dirt, rain and accidental injury. The motors were furnished to the machines in accordance with the amount of work that the latter might be doing and not necessarily of a power equivalent to the full capacity of the mechanical plant; and changes in the motors have been occasionally made, as the work required to be performed by the mills, hoists, etc. has been changed. It may be mentioned that the charges made by the Exposition Company to the contractors for the power and use of the motors are based upon the average daily maximum load taken by instrument readings.

VII.

The results, as predicted by the electrical engineer, his assistant and the staff of the construction department, have proved to be eminently satisfactory, and the champions of the portable steam engine and boiler operation of saw-mills, hoists, etc., have lowered their flag in favor of the electric motor. The work done by the motors has also showed conclusively that they could be loaded largely in excess of the rated capacity momentarily without sparking, burn-outs or any injurious results.

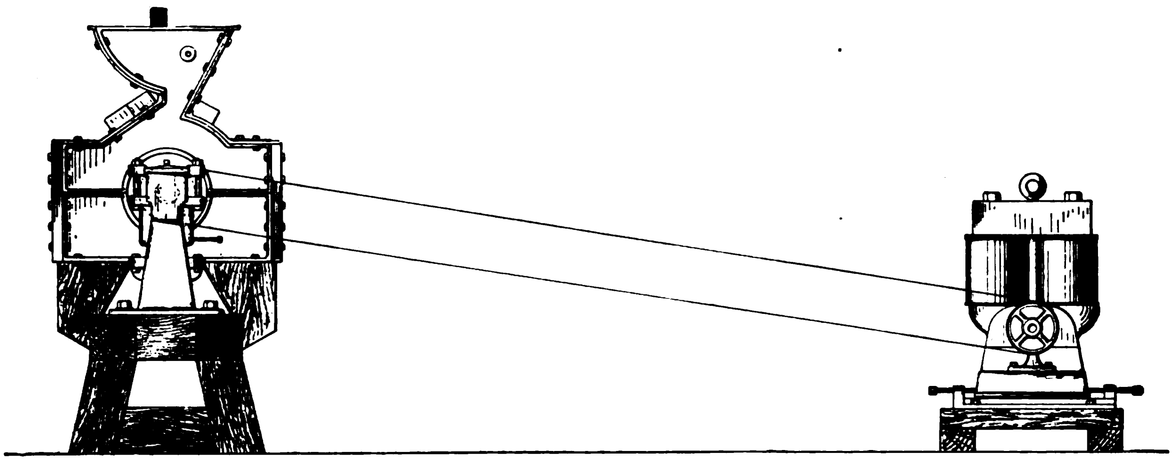

FIG. 7.—AUTOMATIC PULVERIZER, WORLD'S FAIR GROUNDS.

The entire plant is leased by the Exposition Co. from the Edison General Electric Co. and is to by returned by Jan. 1, 1893, in as good condition as received. This transmission is quite an important one, although temporary, on account of its magnitude, the long distances separating the various plants, and the necessity of having the power of easy access for tapping, at any point within the entire grounds, where it may be required. The motors cover a scattered territory about a mile north and south by about half a mile wide. The absolute freedom from accident or failure of any kind which the plant has enjoyed from the outset proves convincingly that this means of transmission is as reliable as, even if not more so, than any other known method.

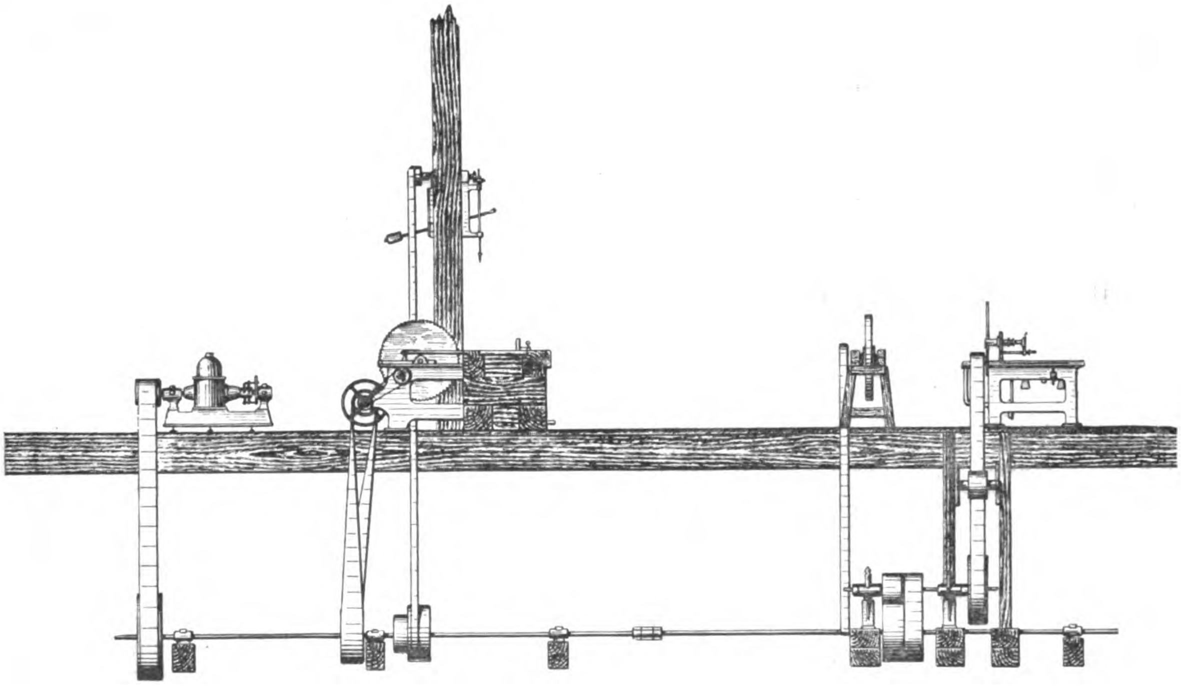

FIG. 8.—SAW MILL IN MACHINERY HALL.

It will be a pleasing thought to electrical engineers and those interested in the electrical industry both in our own country and from all parts of the world, when they visit the great Exposition in 1893, to remember that electricity was the power employed for raising these mighty structures.

RESISTANCE OF COBALT.

PROF. C. G. NOTT, in a paper to the Proceedings of the Royal Society of Edinburgh, comes to the conclusion experimentally that between the temperatures of 400° C. and 700° C., the resistance of a cobalt strip increases on an average at a rate nearly twice as great as the average rate of increase between 0° and 300° C. He also investigates the thermo-electric position of cobalt.

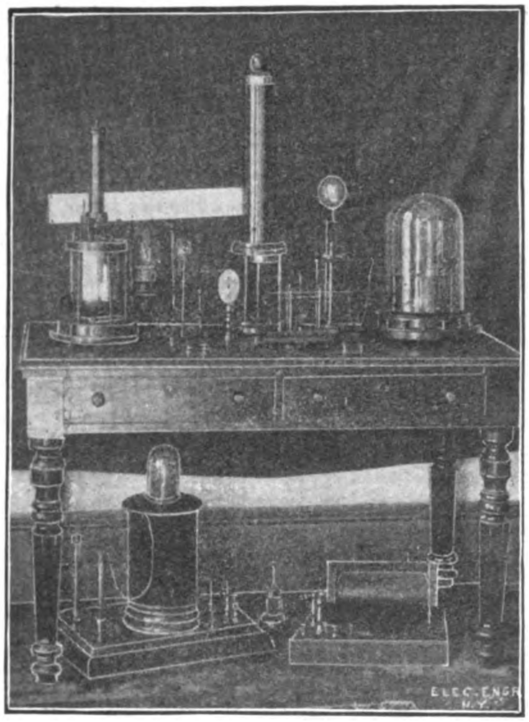
INSULATED ELECTRIC CONDUCTORS.[1]—II.

BY

James Bowstead Williams M.D.

CHAPTER II.

THE electrical testing apparatus consisted of a quadrant electrometer with its replenisher and gauge in a separate vessel; a lamp, lens, shield and scale; a coil giving five-inch sparks, and cell for operating it; a discharge key with a supporting arm for short wires fastened to its base; an upright cylindrical air condenser; and a battery of 24 cells. The greater portion of this apparatus is shown in the accompanying illustration of a group of instruments made by the writer. In the illustration accompanying the succeeding article, the same instruments, arranged for testing, will be shown in enlarged views, with reference letters added for convenience of description. The replenisher and gauge will be added to the group in this illustration and the air condenser omitted. When first constructed, the needle and mirror of the quadrant electrometer were suspended by a single cocoon fibre about eight inches long. The mirror, of the kind described by the writer in an article in the *Electrical World* of July 23, 1887, had a short magnetized needle cemented to the back, and the needle system was directed by a cylindrical magnet mounted on an adjustable swinging arm secured to the cover of the jar. This arrangement, although a very sensitive one, was soon altered, for reasons which will become apparent when describing the action of the instrument, the magnets and adjustable arm removed, and a bifilar suspension, with the necessary adjusting devices, substituted therefor. The quadrants are not mounted upon glass pillars, as in the Thomson electrometers, but are suspended from a circular plate of prepared material the insulation of which is not affected by any small amount of moisture which might be present in the jar. The back, quadrants are stationary, but the front ones are capable of adjustment from the outside. The insulation of the quadrants is so perfect that they will remain charged at potentials of 5,000 volts and upwards for hours without any perceptible leakage. Perfect insulation of the electrometer, and also of the discharge key and its supporting arm is absolutely necessary when the instrument is to be used for determining the comparative insulation resistances of insulated wires in lengths of one inch and upwards. The electrodes of the quadrants and of the needle and induction plate are similar to those of the Thomson instrument and have the same adjustments. The screen has a round hole bored through it, across which is stretched a fine black wire; this causes the spot of light which moves along the scale to appear as a bright disc with a perpendicular dark line or band (the image of the cross-wire) drawn across its centre.



GROUP OF TESTING APPARATUS.

The scale is divided into 300 equal divisions by lines $\frac{1}{20}$ of an inch apart. The spaces between the lines are wide enough to allow the image of the cross-wire to be easily seen when it is passing from one line to another along the scale. The battery (not shown) consisted of 24 zinc-copper cells secured in the containing case and at proper distances from each other by a filling or layer of paraffine. This layer was thick enough to insulate as well as isolate the cells from each other and from the bottom and sides of the case.

The discharge key resembles the ordinary form, as made in this country, with the exception of the trigger, the hook of which is more highly insulated than that of the keys in general use. On the base of the key is mounted a stout pillar about eight inches long to the top of which is secured a horizontal swinging arm. This arm carries two adjustable supports, each of which has a **U** shaped depression formed in the upper part, in which pieces of insulated wires are held while being tested. The pillar, arm, supports and set-screws are all made of hard rubber. The air condenser had but two concentric coatings. The outer one was formed of a brass tube and rested in a groove turned in a ring of insulating material. This ring was supported by three hard-rubber pillars and was highly insulated. The inner coating was a solid cylinder and was supported by a single hard-rubber pillar. All of the edges of the metal were rounded off and made smooth, so as to prevent any dissipation of the charge of the condenser. The replenisher and gauge will be described in the next article.

Digressing for a moment from the line of my subject I will now refer to a difficulty which doubtless has often been encountered by many who use electrical instruments for measuring high potential currents. I mean the surface leakage of hard-rubber pillars and supports. I found that, in order to prevent surface leakage on the exposed hard-rubber parts of my instruments, it was necessary to coat these parts with paraffine wax almost every time the instruments were used; as moisture, particles of dust and other light substances would invariably collect upon the surface of the hard rubber, along which leakage would take place. By "hard rubber" I mean those products commonly called Vulcanite and Ebonite. This material *should* be composed principally of pure india rubber and sulphur and vulcanized at a high temperature for several hours; but, as usually sold, it contains many ingredients which certainly do not increase its insulating properties. For instance, some manufacturers add a large quantity of lampblack (carbon) to the mixture of rubber and sulphur and, in addition to the lampblack, lead and zinc oxides, substances which are cheap and "weigh well," but all of which cause the specific resistance of the vulcanized product to be very much lower than that of *good* hard rubber. Other manufacturers add the dust obtained during the finishing and polishing of articles made of hard rubber to the mixture of rubber and sulphur; and as this dust is generally gathered off the floor it is very apt to contain particles of metal and also of the rouge powder which is used in polishing the manufactured articles.

---

[1] *Copyrighted* 1891, *by James B. Williams, M. D. All rights reserved.*

It is a common thing, while cutting into the hard-rubber rods and tubes on sale in the stores, to encounter pieces of metal and other foreign substances firmly embedded in the mass, proving, by their presence, that they were incorporated with the rubber and sulphur before vulcanization. Another adulterant of hard rubber and, it is to be feared, of rubber *insulating* compounds, is what is known as "recovered rubber." This substance can be obtained from rubber boots and shoes which have outlived their usefulness by cutting them into small pieces and melting the pieces over water (the fire being above), into which the melted material falls. This material is then well washed, dried, and dissolved in a suitable volatile solvent, and the solution allowed to stand until the insoluble substances settle to the bottom of the vessel. The solution is then decanted and the solvent distilled, condensed and retained for future use. The rubber thus "recovered" is worked on rolls for a few minutes, and is then ready for the market, where it is sold for about $10 a ton. Pure Para rubber, the only kind that should be used for insulating purposes, costs at least $1,500 a ton; and the relative values of this and the recovered rubber, for insulating purposes, may be assumed to be nearly in direct proportion to their market values.

After many tests of different qualities of hard rubber and substitutes for the same, the present writer found that nothing but the purest quality of this material could be used in the construction of testing apparatus similar to that described in this article, or of any other apparatus the efficient performance of which depends mainly upon the perfect insulation of the various parts thereof; and in no case could the quality of the material be determined except by actual tests. Furthermore, the writer has yet to find a substitute for hard rubber now on sale which has a specific insulation equal to that of good hard rubber, or which can be substituted for that material for insulating bodies charged to a potential of (say) 2,000 volts.[1]

Another trouble experienced in the use of hard rubber is due to the fact that there is always more or less free, *i. e.*, uncombined, sulphur present in this material. This sulphur forms with the moisture present in the atmosphere, acids, and there is therefore a film of acid upon the surface of all unprotected tubes and rods of hard rubber, which not only acts as a first-rate conductor for high potential currents, but gradually destroys the rubber itself. The film of acid also serves as a fixative for dust, etc., which come in contact with the surface of the rods and tubes. Brushing over the surfaces of such rods or rubbing them with a dry cloth does *not* remove minute foreign substances, but simply distributes the particles of dust, shreds of fibre, etc., into new positions upon the surface. The rubbing also electrifies the rubber, and thereby causes it to attract to, and retain against, its surface any light floating bodies in the immediate vicinity; and thus the source of surface leakage which the brushing or rubbing was intended to remove is increased.

By subjecting hard rubber to the following treatment the present writer has experienced no difficulty in insulating different parts of electrical testing and other apparatus. The tube which insulates the sliding electrode of one pair of quadrants of the electrometer will be used for illustration. The tested material is first formed into a tube of any suitable and desired shape, in a lathe, and the tube then washed in a solution of caustic soda in water, to remove any grease and dirt. After the tube has been thus washed, and before it is removed from the caustic solution, it is grasped by a pair of forceps and transferred to another vessel, and there rinsed with clean water until every trace of the soda is removed. This can be ascertained by testing from time to time, during the washing, with litmus or turmeric paper. The tube is finally cleansed by allowing distilled water to run over all of its surfaces for a few seconds, and then dried over a fire free from smoke. Under no circumstances should it be touched with the hand after its removal from the alkaline bath.

The tube is now ready for a coating of paraffine wax, the objects of which are (1) to protect the rubber from atmospheric moisture, and (2) to increase the surface insulation. The tube is supported in one hand by means of a piece of wood or metal (previously prepared) fitted into one end. A clean piece of the *best* quality of paraffine wax is taken in the other hand, held over a lamp until the wax begins to melt, and the melted wax allowed to drop upon the tube until a quantity sufficient to cover it has fallen thereon. The tube is then revolved over the lamp until the wax flows evenly upon its surface, forming a thin uniform layer which, when cold, firmly adheres to the tube. The inside of the tube is paraffined by holding it in a pair of forceps, dropping melted wax into the ends, and then distributing the wax upon the inner surface by means of a clean rod of metal heated over the lamp. Hard-rubber rods and pillars are paraffined in the same manner as the outside of tubes, the rods being supported by a rod of wood or metal fitted into a hole bored in one end.

A rod, 8 inches long and ½ inch in diameter, prepared for use in the manner above stated can be used to insulate bodies charged to a potential of about 10,000 volts provided that the rubber be of good quality. Great care must be taken to not overheat paraffine while applying it to supporting rods, tubes, etc., because if heated above 250° F. decomposition begins and its high specific resistance is diminished thereby. The layer of paraffine can be renewed without removing the insulating supports from apparatus by scraping it with a clean knife, or by passing a heated flat tool over every portion of the layer, which both isolates and insulates any foreign particles from each other and from the surface of the rubber.

If the ends of rods are made concave, *i. e.*, cup-shaped, in a lathe, such rods, when secured by screws to flat surfaces, will afford a much firmer support and be less liable to become loosened by jars and vibrations than if their ends were simply turned true in the lathe. The surface of hard rubber rods can be enlarged by corrugating the rods in a lathe, that is, by forming alternate elevations and depressions from one end of the rod to the other. Such rods, when in an upright position, afford better security against the formation of a continuous film of dirt on their surface than plain rods; because the hollow spaces are to a great extent protected by the ridges above them. But corrugated rods must be carefully watched and paraffined if perfect insulation is to be obtained by their use. It is obvious that ornaments on pillars when formed by a turning lathe, also increase the length of the surface of such pillars.

The surfaces of hard-rubber pillars, etc., may be renewed by rubbing them with clean glass or emery paper. The surface, thus renewed, will insulate as well as the original surface of the newly finished material if moisture from the fingers and particles of dirt have not been left upon the surface after the rubbing.

It is impossible to keep the hard-rubber parts of testing instruments too highly polished if the highest insulation resistance of such parts is required.

Hard rubber, when pure, contains no gritty particles, has a uniform color and consistency throughout the mass, and smooth shavings can be cut from it with a sharp knife. Still, the mere fact that the purchased material does possess these properties is not necessarily a proof of its purity; for oily products, and other substances, can be incorporated with the rubber and sulphur before vulcanization, and which will cause the vulcanized product to resemble good hard rubber but, at the same time, have a specific resistance much lower than that of the pure material.

As before stated, the only way by which we can *know* that we have pure hard rubber is by testing it. A good standard for comparison is pure paraffine wax, as the specific resistance of pure hard rubber is not much lower than that of the wax.

---

[1] The writer would take this opportunity of requesting manufacturers of such substitutes to send thin pieces, measuring 2 x 4 inches or thereabouts, of their products, to his office, at No. 44 Broadway, N.Y. City, for private examination.

THE FORD-WASHBURN STORELECTRO CO.'S STORAGE BATTERY CAR.

While the overhead trolley system of operating street cars has continued to increase the number of its installations with rapidity unequaled in any other industry, the workers after the solution of the problem of doing away with the overhead network and carrying the energy upon the car itself, dispensing with conductors of all kinds, have manfully attacked the diseases of the early storage batteries. Mr. G. A. Ford and Mr. George Washburn, of Cleveland, have devoted time and money to the problem, and, after numerous experiments, have perfected and brought out a new form of storage battery and a complete system of electrical storage traction, which, they believe, combines all the requirements of a practical and commercial system. In view of the great importance that attaches to the subject, the subjoined details will be found of more than usual interest. While the trolley is all triumphant at the moment, there are many electrical engineers who look confidently for the ultimate victory of the storage car, and there are many places where without it electricity remains debarred.

In attacking the problem it was decided that a radical departure in the forms of storage battery was necessary to successfully cope with the difficulties and severity of street car service, and that the main features that must be provided in a commercial system were as follows: The cells must be capable of withstanding the heaviest discharges, even to dead short-circuit, without injury. Short-circuits must be impossible within the cells. The batteries must be durable, and require, practically, no attention; be cheap and of good efficiency. Buckling or falling out of active material must be impossible.

To fulfil these conditions and provide a commercial battery, it was determined in the first place to dispense entirely with plates, in the strict sense of the word, and employ conducting receptacles containing and in intimate connection with the active matter, the positive and negative elements of which should be separated by a porous low-resistance mechanical partition instead of space, as heretofore employed.

These form important and radical features of novelty in storage battery manufacture, and are the principal points in the Ford-Washburn cells, of which the following more detailed description will clearly show the method of construction. The dimensions of a 150 ampere-hour cell, as used for street car work, are 12 inches high by 4½ inches by 8 inches, weighing, complete with acid and rubber box, 40 lbs.

In the latest form there are five sets of elements, comprising four positives and five negatives, surrounding the former on all sides. The arrangement is exceedingly simple. An outer casing, made of specially prepared lead to withstand the action of the acid and deterioration, perforated with small holes so that the acid can percolate through but the active material cannot by any possibility get out, is formed into a rectangularly-shaped cup or receptacle, comprising, with its active material, a negative element. Inside this is placed a porous pot of special manufacture, which in turn contains active material surrounding and in intimate relation with a conducting medium of perforated lead, which is so constructed as to take care of the expansion and contraction of the active material during charge and discharge, and forms a positive element.

The negative elements are all connected together by a solid lead strip welded to the *bottom* of each receptacle—a new departure in accumulator work—and are also all touching one another and therefore in good electrical contact at numerous points, a result of course unattainable in a plate cell, as the plates are arranged alternately positive and negative. The positive elements are similarly connected but at the *top*. This method of connection is employed from the consideration that a more evenly distributed discharge is thus obtained and extra strength given to the battery. The positive elements are by this means entirely surrounded by the negative, and have a large surface of active material exposed to the electrolyte; and as the thickness of the porous partition is only ⅛ of an inch, the internal resistance is quite unappreciable. A short-circuit between the two is impossible as the porous pot is between them and extends a trifle above the receptacles at the top so that the positive and negative active material is at all times kept absolutely separate. The sets of elements are placed in hard-rubber boxes and for street railway work hermetically sealed and put in the car, as they require no inspection at frequent intervals and no attention except to replenish the acid when required on account of evaporation. This, however, as the air is kept from the interior of the cell, need only be done at long intervals.

An interesting experiment and one which is constantly made with any and all of these cells is to short-circuit them through an ammeter capable of reading up to 300 or 400 amperes and discharge them completely at the highest possible rate, which instead of injuring the cells at all, does them good, according to the inventor. The heavy discharge the cells give under this severe test shows their low internal resistance.

The appended table shows a test of a cell on a resistance giving volts and amperes taken every 15 minutes during a period of six hours. At the expiration of this time the cell was not by any means entirely discharged and if allowed to rest for a time the voltage would have risen again to very nearly normal. There is no necessity of leaving in any initial charge as these batteries can be entirely emptied without any injurious effects.

Readings from one cell.

The Ford-Washburn Storelectro Company have equipped the fine car shown in the accompanying illustration complete with their system of storage battery and motor and have named it "The Ideal." This car has been run all over the several lines in Cleveland up grades and around curves and under all kinds of conditions such as exceedingly heavy loads, drawing trail cars, etc., and has showed itself perfectly satisfactory, it is said, and capable of performing any work upon which it was put. The car is 28 feet long over all and 21 feet inside, and was built by the Brill Company, of Philadelphia, specially for the purpose. It is exceedingly attractive, painted white and gold, fitted with French plate-glass windows, hard fancy wood interior finish, and handsomely upholstered and equipped with ratchet brakes and all the latest improvements. Under the seats are placed the batteries, in three rows of 30 cells each on either side, making 180 in all. By means of a a mechanical device all the batteries can be quickly run out at either end of the car and another set run in if desired. It takes about three minutes to effect the change. The weight of the cells complete is 7,200 lbs. The car body is mounted on a modified Tripp truck with special extension springs and having a wheel base of seven feet and 33-inch wheels.

It is equipped with a single 35 h. p. Ford-Washburn motor capable of working up to 40 h. p. for an indefinite period and weighing about 2,000 pounds. The armature of the motor is lengthways of the car and is fitted at the end of its shaft with a pinion gearing with an intermediate gear on a shaft passing between two of the field coils and suitably supported in bearings. At each end of this shaft is a bevel pinion running a bevel gear on each axle thus transmitting the power positively to both axles.

The motor is series wound, the field being in sections arranged for commutating for obtaining variable speed. There are four coils each divided into three sections, the field having four magnet cores and being of the consequent pole type with yokes at each end and made entirely of best quality of wrought iron. The Ford-Washburn ventilated armature similar to those of their stationary motors is employed, and a modified Siemens winding is used.

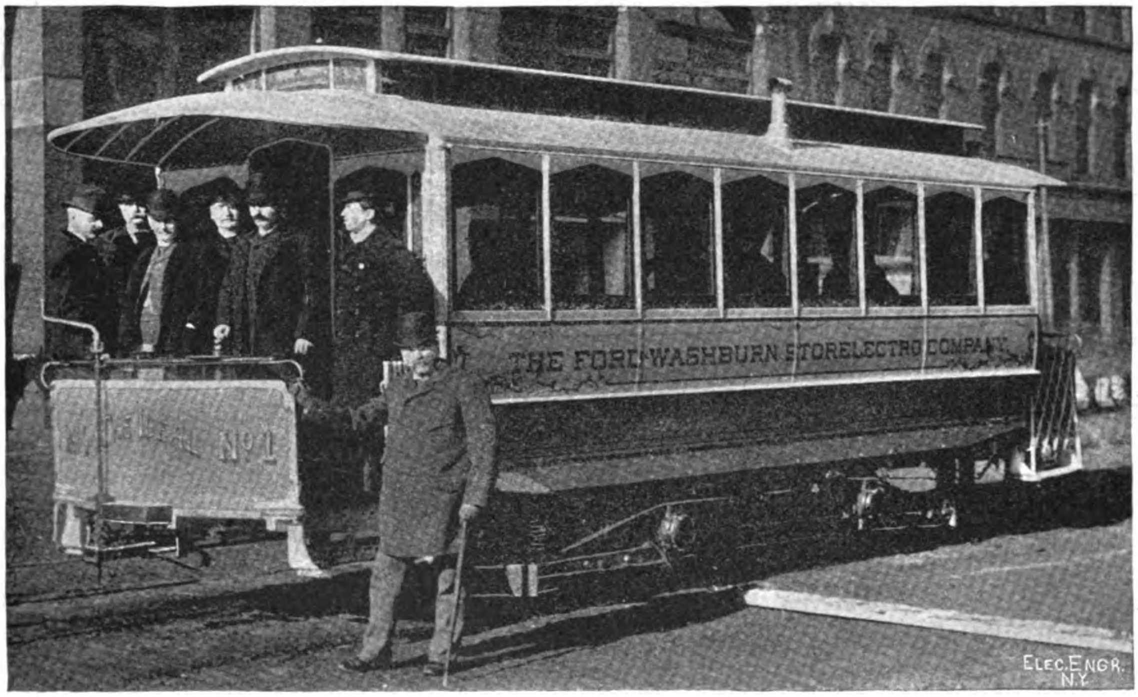
On this car there are two variable speed arrangements, the first dependent on the means of coupling the batteries by which three speeds are obtained; with four sets in multiple of 45 cells each, giving 90 volts; with two sets in multiple of 90 cells each, giving 180 volts and with the whole 180 cells in series, giving 360 volts.

The second consists in commutating the field by which four other changes in speed can be obtained; first, all coils in series; second, one section of each field coil cut-out; third, two sections cut-out and fourth, all in multiple. The arrangement of the coils and sections is such that the magnetization of the magnet cores is at any time similar, with respect to one another. By employing the two methods together, wide variations in speed can be got. The various changes are carried out by means of a switch lever provided with special reversing switch at either end of the car. A further special switch for instantaneously shutting off the current is placed at each end of the car and connects between batteries and motor, to be used in cases of emergency.

In starting the car, the field coils are all cut in with four sets of the cells in multiple taking about 15 amperes of current. With the highest speed at which the car ordinarily runs, from 15 to 18 miles an hour on a good level track, about 20 amperes are absorbed; on heavy grades from 35 to 40 amperes is about the maximum. It would seem from the severe tests to which this car has been subjected and the small attention it requires that this system is likely to be largely used and there appears to be no reason why the batteries, which are the important factor in work of this kind, and in this case are of so remarkably simple and effective construction, should not prove to have a singularly long life, even on the severe strain of street railway service. It is a noteworthy fact that their renewal is of no costly nature.

On a trip made early this month over the Woodland Avenue and West Side and East Cleveland Street Railway Companies' lines of 16 miles with 35 passengers, the average current absorbed was 20 amperes at 350 volts. Three and three-tenths miles were run in 12 minutes. On the route named there are 23 sharp curves and 10 grades ranging from two to five per cent.

The writer has had the pleasure of examining the storage battery used, in various processes of manufacture, and inspecting the car and its equipment, and taking several extended trips over some of the lines both of the overhead and horse car systems, and noting the ammeter and voltmeter readings on the car while in actual service of starting, climbing grades, rounding curves, and so forth; and the results achieved are certainly very encouraging.



Storage Battery Car of the Ford-Washburn Storelectro Company.

AN AUTOMATIC POSTAL CALL-BOX.

A very ingenious automatic machine has been established near the letter box at Charing Cross Station, London, for the collection of letters to be forwarded by the Post Office Express Service. It is in electrical connection with the Postal Telegraph Office opposite the station. By dropping a penny into the slot, and pulling out the slide, a brown-colored envelope is delivered. This envelope contains another envelope and a card. The communication is intended to be written on the card, which is then enclosed in the white envelope, and this, with the fees for delivery, which have been fixed at three pence per mile, is re-enclosed in the outer envelope, and deposited in the box behind the flap, which bears the printed instructions. The act of withdrawing the slide sends the call signal to the telegraph office, and a messenger is at once dispatched to collect the special letters.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, MARCH 23, 1892. No. 203.

It is better to be aware, or even to suspect we are wrong, than to be unconsciously or easily led to accept an error as right.—Faraday.

THE GROUNDING OF THE NEUTRAL IN THE THREE-WIRE SYSTEM.

IT has been for some years past the general practice among companies operating low tension three-wire circuits, more particularly among the various Edison illuminating companies in the country, to ground the neutral. This practice was introduced in a few stations as an experimental protection against lightning, and for a long time met with no opposition on the part of the underwriters, but it would appear that a recent fire in New York has brought forward prominently the question of the possible dangers involved in this practice. The New York Board of Fire Underwriters, at their last meeting, went even so far as to pass a resolution requiring the electric companies to remove all such grounds now existing on their circuits before October 1, 1892, and to make regular weekly reports of the tests of their circuits as called for in the requirements of the Board, failing in which the superintendent of the Survey Department is directed to decline to grant certificates. As this question is one involving very large interests it may be well to discuss it in order to bring out some salient features with regard to the practice of grounding the neutral, which are not generally understood.

Before proceeding, it may be well to state that the grounding of the neutral is no essential part of the three-wire system, and was not even considered desirable for several years after a number of such systems were constructed, and is now only used as an emergency expedient. It must be generally admitted that the absolute insulation of all the sides of the three-wire system, if it could be practically accomplished, is the most complete safeguard against dangerous leakage, and should be followed wherever the circumstances permit of it; or, to put it in other words, if such a system can be kept free from ground permanently the neutral wire need not be, and ought not to be grounded. Again, if a thoroughly insulated system be so constituted that a ground can be at once located and a remedy speedily applied, it would also be preferable to maintain the neutral insulated. But those who argue absolutely for the insulation of the neutral wire seem to leave out of account the fact that the conditions here assumed are more ideal than real. If we take, for example, the case of New York City, in which the Edison Electric Illuminating Company has over seven hundred and fifty miles of underground conductors directly connected to many thousands of lamps, and that these conductors are subject to many disturbances, both below the streets and within the interior of houses, that lamp sockets are frequent sources of grounds, etc., it will not be difficult to conceive that the maintenance of high insulation on such a system is a practical impossibility, and that with no other than a low tension source of energy could such a system be operated at all. We might go farther and say that the normal condition of such a system is a grounded one, in spite of all precautions that can be taken.

This being the case, the argument of those in favor of insulating the neutral would hardly seem to apply, while, on the contrary, those who argue in favor of the grounding of the neutral insist that fire risk is reduced; for, if a ground on the neutral wire in a building occurs it will be in no danger, while if on one of the other conductors it would blow the safety fuse and do all the damage of which it was capable, at once. On the other hand, if the neutral be insulated the fuse would not be blown till the appearance of another ground on the opposite side of the system, and this might occur during the absence of the occupants of the premises. It is also argued, and we think rightly, that the grounding of the neutral reduces the harmful pressure (that is, the pressure to earth) to 110 volts although the total difference of tension employed between the two outside wires is 220. The opponents of the grounding of the neutral insist that the insulation of the neutral ought to be maintained, but as grounds would of necessity occur and require time to locate and would necessitate the obtaining of permits to dig up stone-bound or asphalted streets, etc., it must be evident that such a rule would work enormous hardships on large companies. The insistence also on the rule requiring insulation tests of such a ramified system operating at low tension practically means the complete cutting off of the tested section while instruments were to be applied at frequent intervals, a step which we think will hardly be insisted upon as it would simply render the entire plant unreliable and hence prove a much greater difficulty than that which it is intended to forestall. It would be analogous to asking the gas companies to make periodical tests of their pipes under streets and to report their leakage. It is true that a leakage in the gas main brings no additional strain on the gas pipe in a building as is the case in the electric system, but as is shown above, a ground on either the positive or the negative conductor inside the building is at once made manifest when the neutral is permanently or periodically grounded, by the blowing of the fuse. While, of course, no reduction has ever been made in the amount of copper used in the construction of any Edison three-wire system because of the adoption of this expedient, the earth may nevertheless under certain conditions, reinforce the neutral no matter how large its cross-section may be, and thus aid in tiding over a sudden overload of one side of the system.

Besides the reduced fire risk claimed for the grounded neutral, the advocates of the latter point to the fact that it affords protection against lightning, particularly at the station and at the ends of extreme conductors of the system. Again it is of value as a means of keeping the corresponding middle conductors of two neighboring three-wire systems (usually operated separately) at the same potential, so that if it becomes necessary in an emergency to interconnect their conductors, either through their central stations or elsewhere, they can be so connected without any disturbance in their operation or danger to the apparatus. But perhaps the best proof of the value of the grounded neutral is the fact, established by experience, that whereever the neutral has been grounded, the "troubles" ont he circuits have been greatly reduced.

It is also pertinent to state that the action of the New York Board of Fire Underwriters in this matter is not in accord with the "National Code" adopted by the National Electro-Insurance Bureau, in August of last year, in which we find the following rule:

> In three-wire or other compensating systems, the intermediate conductor may be permanently connected to earth, provided facilities are furnished for automatically testing the insulation of the positive and negative conductors.

This Code is in force in about fifteen or eighteen States in the West and it now seems probable that it will be adopted at an early day by the Southern States and those on the Pacific coast. Nor must the fact be lost sight of, that in New England, where the most painstaking and intelligent inspections have been made for the past six years, the inspectors have been disposed to approve the grounding of the neutral, Capt. Brophy, among others, being, we believe, in favor of this practice.

While this controversy is still going on in this country it may not be out of place to draw attention to a similar case abroad which involves questions of as great, if not greater, technical and commercial importance. Our readers will recall the fact that Mr. Ferranti transmits alternating current at 10,000 volts from the station at Deptford into London, a distance of five miles, and employs for this purpose a concentric conductor. When Mr. Ferranti broached his plan of grounding the outer conductor in order to obtain immunity from dangerous shocks, he was met by much the same opposition as is now being manifested here, but after a full and complete argument of the case on both sides, the London Board of Trade gave its consent to the practice which is in vogue at the present time. If the New York Board of Fire Underwriters are looking for a precedent they would here have one of no little importance; and a calm survey of the situation with all the testimony for and against the practice should be taken before the intended revocation of certificates is effected. We understand that the local Edison Company if compelled, will take off the ground from their neutral, thus putting the responsibility for the change upon the underwriters.

THE TROLLEY FOR PHILADELPHIA.

LAST week, the Railroad Committee of Councils in Philadelphia decided by a vote of 14 to 4 to report favorably to Councils the ordinance granting permission to the Traction and People's lines to use the trolley system along certain streets. This looks as though Philadelphia will soon be in line with the rest of the country in the adoption of electric locomotion.

The rapidity of the introduction of the overhead trolley system has been extraordinary, and can only be accounted for on the supposition that it meets and fills one of the greatest wants of modern American communities. Of the 16 cities of the United States having over 200,000 inhabitants, 14, or 87 per cent., are equipped with electric roads. Of the 42 cities having between 50,000 and 200,000 inhabitants, 41, or 97½ per cent., have electric roads. Of the remaining 391 American cities that have a population over 8,000 we do not know of a score that have not electric roads or serious plans for establishing one.

These figures are certainly eloquent, and are among the most convincing arguments that an advocate for electric traction can present. They show that only two large cities, namely, Philadelphia and New Orleans, and only one relatively small city, New Haven, remain without an electric road; and all three, we believe, will soon be included, if present plans are carried through. The triumph of the system is wonderful, but not less wonderful is the fact that the apparatus that has already assisted in the locomotion of passengers equivalent to the population of the globe, but has not injured a single soul, should be ignorantly characterized by medieval journalists as "the deadly trolley."

It seems to us that this very rapidity of introduction of the trolley should encourage those who are working to make storage battery traction a commercial and economical success; and we are glad to note that the work in the storage field is kept up, with ever increasing promise of ultimate success. One of the articles in our current issue tells of some remarkable recent work in Cleveland.

Non-Arcing Metals.

THE early days of the telegraph did much to stimulate inventive genius to devise means for protecting the lines and apparatus from lightning, and with the coming of the telephone and the electric light came additional devices, based on various phenomena. Much of the energy of recent years in this direction has been devoted to the avoidance in such apparatus of all electro-magnetic coils which might impede the discharge of the lines to earth. The record of the work done in this direction by Mr. Alexander J. Wurts, as given in his Institute paper, in another column, is an excellent résumé of labors in a particular line, and the results to which they have led Mr. Wurts are of the greatest practical value. He shows in effect that for alternating currents, at least, we are placed in possession of materials for the practical extinction of arcs, and it would be strange if the discovery here made should not be applied to a large number of electrical devices in which destructive arcs are now liable to occur. The discovery is unquestionably one of the highest practical importance.

HOW ELECTRICAL COMPANIES MAY ENHANCE THEIR REVENUES WITHOUT INCREASING RATES.

BY

D H Babcock

APPARENTLY many of the electrical companies are not making any money, and as a consequence are not paying dividends upon their capitalization. In the rapid development of these enterprises the companies, as well as the general public, have underestimated the cost of producing the electric current which so brilliantly illumines our streets and buildings.

In an able paper read before the recent Electric Light Convention, in Buffalo, the Hon. Erastus Wiman makes an interesting presentation of this condition of things, and the causes that have led thereto. In the first place, the supplanting of a long-established system of lighting, even to a degree, could not be accomplished without a struggle. The competition between electricity and gas would naturally reduce the price of gas to consumers, which would influence in the same direction the rate for electricity. In the enthusiasm of this rapid development, the promoters have underestimated the cost of producing the electric current, and have not demanded that increase in price which a superior article should claim by right over an inferior in all markets.

An electric lighting plant is a complicated and expensive investment, subject to loss and depreciation. We have, first, the boilers as the foundation of the work to be done; second, engines of high efficiency to develop the necessary power; third, the generators of the current to be distributed; and fourth, the circuit of wires, over which the product is to reach customers.

In the early stages of such an enterprise, the bookkeeping may show a profit in operating, but afterward, the depreciation, the cost of repairs, and the substitution of new machinery is apt to place the balance on the reverse side of the ledger. As Mr. Wiman says: "One misfortune has been in electric lighting that a large investment has been available for only a short time. All day long, when other works, by rental or by active employment, were earning money, electric light plants have been compelled to stand idle. Even gas companies spend the whole day making gas, accumulating in their reservoirs for distribution during the night. Electric light plants, however, are compelled to manufacture and distribute at one and the same time."

An enterprise of such merit, and a commodity in such demand by the public, will not be allowed to fall into disuse; either the companies will increase the rate to customers, more nearly to correspond to the cost of production, or means will be found to supplement present rates by more economical methods, or rendering available forces or material now wasted through neglect or imperfect information. In support of this last idea, it may be stated that the steam at the station, after passing the engines, still has a value for heating, and may be made an item of vast importance, as can be shown in actual work. In all non-condensing engines, after the steam has done its work, it is calculated that nearly nine-tenths is still available for heating. This may then be termed a by-product.

There are many branches of manufacture, which might be named, whose profits come mainly from the utilization of these by-products. They are legitimate sources of revenue, and a neglect to profit from them would be considered wasteful to the last degree.

How can this by-product of exhaust steam be made to profit the owners of stations who manufacture the electric current?

Simply by laying properly constructed underground mains from the station, out through the streets of a city, where it may be distributed to houses, stores, offices, churches and public buildings. Heat is quite as indispensable as light in the economy of affairs. A temporary suspension of light would not endanger health and life, but it would be impossible to live in health for a day in our houses without heat artificially supplied during the inclemency of our winters. And no medium of heating is so popular, or being adopted to such an extent, as is steam. Another reason which recommends this practice to the managers of electrical stations is, that during eight or nine months of the year it keeps the labor at the station constantly occupied. The boiler plant is in active operation during every hour of the day. Interest on any investment counts constantly against earnings. If the plant is idle half of the time it is at a disadvantage. Here is a way to turn waste material into money and to keep men and plant from rusting in idleness. During lighting hours heating is supplied from exhaust, which costs nothing; during the remainder of the time live steam takes its place. There is little or no increase in office expense on account of this added business.

I have in mind an electric plant in a town of less than 20,000 inhabitants from which the exhaust steam is used in the way indicated. The power station contains three boilers of 100 h. p. each, and one boiler of 150 h. p. The company has constructed 4½ miles of electric railway, which is run 18 hours out of the 24. It also does a large amount of lighting, and this part of the plant is in use 12 to 14 hours per day, so that in this case some power is required throughout the entire day and night. To circulate its exhaust steam the company laid about 2½ miles of underground steam mains, composed of 10, 8, 6, 5 and 4-inch pipes. In this pipe a steam pressure of from 12 to 15 lbs. is carried. This produces a back pressure on the engines, which is overcome by increasing the boiler pressure to that extent. This condition does not embarass the action of the engines in the least. This steam plant is now being operated the third season. The first year the company had 36 consumers, the second year 69, and at present it is carrying 138 consumers. All of the churches located on the lines, school houses, many residences and public buildings have embraced the opportunity to relieve themselves from dust, gas, and smoke and the storage of coal. The Government Building is heated for $450 a season. Residences pay from $90 to $140 each. The 138 consumers on an average probably pay more than $100 each. Meters are used, and each customer pays for the amount of steam consumed.

In mild weather the heating is all done with the exhaust from the station; during a cold snap some live steam is taken from the boilers by an automatic device, which supplies live steam when needed, and closes when the exhaust is sufficient to supply the demand for heat. It is believed that the net earnings from this heating portion of the plant will pay 6 per cent. upon an investment of $150,000, the investment for steam mains being less than one-fourth of this sum.

The business of this company is now in a highly prosperous condition; made so, to a very great extent, by its adoption of heating by exhaust steam, which otherwise would be turned into the open air and lost.

I have mentioned the case of this company to show what may be done by many other electric companies to aid in placing them on a prosperous working basis. Other plants are already working in this way, and I think the plan is bound to receive quite general attention.

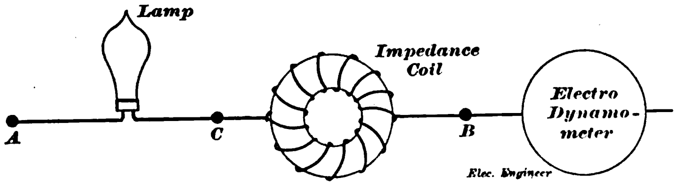
THE EFFICIENCY OF THE RIES REGULATING SOCKET.

BY

Henry Stott

THE following test of the Ries socket for varying the candle power of lamps supplied with alternating currents, was made with a view of determining the efficiency of the device and the writer now publishes the result in the hope that it will prove a useful supplement to the interesting article by Mr. Hammer in the March 9 issue of THE ELECTRICAL ENGINEER.

The socket tested was marked "50 volts, 25 c. p.," but as no 25 c. p. lamps were at hand a 16 c. p. was used and from the fact that, when the switch was on the last step, putting all the coils in circuit, the filament only gave a dull red glow of about a quarter of a candle power, it seemed quite well suited to this lamp.



The method of carrying out the test was one described by Messrs. Ayrton and Sumpner, with a slight modification to suit the case, the rationale of which is briefly as follows, referring to the accompanying diagram:

Let V_1 = Difference of potential between points A and B.
" V_2 = " " " " A and C.
" V_3 = " " " " B and C.
" r = Resistance of lamp.

The watts expended in coil $= \dfrac{V_1^2 - V_2^2 - V_3^2}{2\,r}$.

As the resistance of the lamp was a variable, an ammeter on the dynamometer principle was inserted, and the value $\dfrac{V_2}{a}$ substituted for r, a being the current measured in amperes.

The formula then becomes $W = \dfrac{V_1^2 - V_2^2 - V_3^2}{\dfrac{2\,V_2}{a}}$

$$= a\,\frac{(V_1^2 - V_2^2 - V_3^2)}{2\,V_2}.$$

All readings were taken simultaneously, the volts being read on the Weston type of voltmeter by simply releasing the spring, which stops the motion of the needle, at the same moment that the ammeter was read, and the reading noted before again releasing the needle. The ohmic resistance of the coils was determined immediately after the test by the ordinary bridge method. The paradox of the sum of two E. M. F.'s being greater than the E. M. F. supplied is well illustrated in the table given, as in one case it exceeds the E. M. F. on the mains by 13.5 volts. The accompanying table gives the results of the test and shows the efficiency of the socket at various degrees of incandescence of the lamp.

No. of contact on switch.	Impressed E. M. F. (V)	Volts between lamp terminals (V_1)	Volts on coils in circuit. (V_3)	Amperes.	Resistance of lamp.	Resistance of coils.	Apparent watts in lamp.	Apparent watts in coils.	Apparent total watts.	True watts in lamp.	Total true watts.	Ohmic loss in coils.	Inductive loss, hysteresis, etc.	Total watts lost in coil.	Efficiency in %, or ratio of total watts used to watts absorbed by lamp.

THE RELATIVE ECONOMY OF HIGH AND LOW SPEED ENGINES IN ELECTRIC RAILWAY WORK.

BY

Lemuel Wm. Serrell.

MR. WASON'S tests on the use of high and slow speed engines for electric railway work, as given in the last number of THE ELECTRICAL ENGINEER, are apt to be somewhat misleading.

By looking at the results of these tests there seems to be no great difference in the economy of the high and slow speed engines. But by looking at the last line the average horse power per car was 6.86 h. p. with the high-speed engines and 7.59 h. p. with the slow-speed engines, showing that the cars carried more people during the slow-speed engine test; that is, each car took 10.6 per cent. more power to run it.

The number of pounds of coal burned per car mile run are, respectively, 6.57 lbs. and 6.38 lbs., and as the slow-speed engines did 10.6 per cent. more work than the high-speed engines, on the basis of the same amount of work each, the slow-speed engines only took 5.7 lbs. of coal per car mile run, or 13 per cent. less than the high-speed engines. That the view here taken is correct is proved by taking the water evaporation and the h. p. hours and reducing to the number of pounds per h. p. per hour; we then find that the slow-speed engines took just 13 per cent. less steam than the high-speed engines per car mile run.

There is no question in my mind about the economy of slow-speed engines for all classes of electric work. I have, indeed, redesigned some electric light stations so that a saving of 50 per cent. in their fuel bills could be accomplished.

HIGH POTENTIAL TRANSMISSION.

BY

Elihu Thomson

THE electrical engineer, when he has before him the problem of conveying electrical energy through comparatively great distances, without excessive loss and without excessive amounts of copper in the conductors, is compelled to consider the use of high potentials. Of course, potentials are high or low relatively to others taken as standards, but by a sort of common consent it has come to be regarded that, when the E. M. F. is sufficient to cause the current to leap, or when there is a striking distance which is easily perceptible, the case may properly be called "high potential." It implies the existence of thousands of volts potential difference. The strain on the dielectric or insulating material is such that a high insulation resistance is demanded to prevent large leakage. The current passes at a "high tension," or is a "high tension" current. The time at the author's disposal will not permit more than a brief reference to different combinations of apparatus in which high potentials may be effectively employed.

Let it be desired to transmit several thousand horse power from a water-power to a distance of, say, twenty miles or more, and deliver it at one point as power. What plant should we use? Direct current, or alternating current? Owing to the difficulty of constructing commutators which are suitable for such high potentials as five thousand volts, especially where the current is large, it is evident that neither dynamos nor motors can be used in which the full potential is either generated or used. This assumes the use of a direct or continuous current as the means of transmission. In such case, either the voltage must be kept down to, say, 1,500 to 2,000 volts, or the dynamos and motors must be run in series sets.

It is questionable whether commutators can be commercially successful on which the pressure exceeds 1,500 to 2,000 volts, with large currents flowing. They are very difficult to construct and to maintain. Besides, they require to have so many segments between the brushes that the armature winding and connecting is made more delicate and liable to injury. The cost of construction becomes excessive. When the voltage does not exceed 1,000 volts these difficulties do not present themselves. Hence to use continuous currents in the case assumed and to take advantage of a high line-potential to secure immunity from line losses and allow a moderate outlay in copper to suffice for the transmission, it will be necessary to connect several dynamos in series in the generating station and several motors in series at the receiving station. These machines may be belted to a common shaft. With this arrangement it would be possible, by mounting the machines on insulating bases, to work with such high potentials as 20,000 volts by having 20 machines of 1,000 volts each connected in series at each end of the line. This with each machine of 500,000 watts output, would transfer energy at the rate of 16,000 h. p.

The machines, both generators and motors, could be series wound and be practically self-regulating as to speed under varying loads, providing all the machines are mechanically driven together as one or deliver power together. The construction presents no great difficulties, and the efficiency under all loads, except quite light loads, could be made high. But the condition of combined driving, and delivery of power, destroys much of the attractiveness of such a system. Considerable portions of the plant could not be thrown off without destroying the conditions. There is no method of transformation for direct currents which would not involve the commutator difficulty. It is evident that we must look to alternating currents as a means of transmission at high potentials.

For large transmissions it is evident that the system adopted should permit the construction of dynamos of as large capacity as 1,000 h. p., so as not to multiply machines to too great an extent. It is also requisite that the construction be such that parts are readily accessible and easy to repair in case of accident.

In the employment of alternating currents we have the choice of various ways of working. It is probably not easily practicable to construct alternating dynamos or motors to make use of currents at over 3,000 or 4,000 volts without transformation. It would appear, then, that if the distance is great enough to compel the use of currents at higher pressures than three or four thousand volts, transformation will become necessary; in which case the voltage of the generating dynamos and of the receiving machines can be as low as desired.

But the interposition of a set of transformers for raising the potential at the generator end and another set for lowering it at the receiving end, is an added expense for plant which must be balanced against saving of cost of construction of the machines and line. The percentage of loss involved in the use of transformers, due to losses incurred in the transformation, is not necessarily so great as to be serious. It can probably be brought down to about 5 to 6 per cent. under full load for the double transformation.

In the transmission of power by such a method the losses, then, are those of the line, the double transformation and the dynamos and motors. The total loss need not exceed 25 per cent. under full load condition.

If the transmission is for lighting, and the transformation down at the receiving end is made to give the voltage required for the lamps, the motor losses would be supplanted by losses on the local mains, or local distribution. If motors be run from such lines the losses are of course increased by the drop in reaching them, depending on their distance from the transformers which feed current to them. It will sometimes be found practically impossible to transform down directly to lamp potential from the high potential of transmission. This is the case when it is not permissible to carry the high potential lines to transformers placed here and there in a city. In such cases an intermediate transformation may be resorted to, but it, of course, involves more cost of plant and another three per cent. loss or thereabouts. Dear fuel and very abundant water-power may sometimes warrant such procedures. In all such cases of cumulative drop, difficulties arise from the fall of potential under load, and adjusting devices at the transformers or on the lines may require to be employed.

Fortunately variations in the voltage may, with alternating currents, be effected by the use of variable reactive coils instead of resistances, and regulation may be obtained with fair economy. As regards the single-phase alternating currents, involving the use of but two lines, which is the system commonly used, nothing more is required for such work as lighting, and it is to be hoped that self-starting effective motors may be forthcoming for use on such systems. Progress has certainly been made towards securing such motors and a year or two hence we may find many in active service on existing lines.

For power transmission a reversed alternating dynamo, if of a good type, is also a good motor when brought to synchronism, and it has the advantage of maintaining a speed as regular and constant as the speed of the generators at the other end of the line, but it has also the serious disadvantage of requiring to be brought up to full speed before it will work at all. It is essentially non-starting. Too much complication is introduced into the plant by the introduction of elaborate devices for starting. It has been proposed to start such motors by connection with a small, not necessarily very efficient motor of the self-starting variety, of which there are several quite suitable for the purpose, working by alternating currents of single phase. Where the power is to be delivered *en masse* at a receiving station it is possible that such methods of working may become important. Alternating dynamos are now constructed which, when even of moderate capacity, have a commercial efficiency of considerably over 90 per cent. and therefore approach, if not equal, the best types of continuous current apparatus. These machines reversed and used as motors may be expected to have an efficiency equal to their rendering as dynamos and are easily made self-exciting.

Great interest has recently been excited from the use of the three-phase alternating current, or rotary current, in the Lauffen-Frankfort transmission. This experiment, covering a distance of over a hundred miles, was successful so far as the technical matters involved were concerned. It was not intended as an exemplification of a commercial transmission. It served its purpose in proving the possibility of working with alternating current of very high potentials, and also showed in a striking manner certain features of the multiphase system.

Let us assume that we have a station in which the dynamos are excited by a continuous current, and that the armatures are provided with a three-branched conductor similar to a Thomson-Houston arc machine, but with three collector rings instead of the three commutator segments, three separate brushes bearing on the rings. Or, if the field of the dynamo revolves, the connections are made directly to the stationary armature coils. The three wires may, in other cases, be connected to points in a continuous or Pacinotti winding, such that they are virtually taken at 120 degrees apart in a bipolar machine, 60 degrees in a four-pole, etc. In such cases we will have three lines leading from the generators, in which lines alternating currents may flow with the waves displaced relatively 120 degrees, or in which, when any one current wave is at its maximum, the two others are nearly at their mean value, one rising and the other falling. This has been called a "rotary current" abroad, but it is no more rotary than any current is. In fact, it is no more rotary, as a current, than is steam which is fed by three steam pipes to three cylinders of an engine, in which the cranks are set 120 degrees apart around the shaft. It is true that such currents are capable of producing a rotary magnetic field, just as is a two-phase system, but a rotary field is also produced by the rotation of a set of brushes around a commutator attached to an armature of the ordinary continuous current type, such a current being passed in by the brushes.

By the use of transformers, the three-phase alternating currents can be transformed up or down as with a single-phase current. Specially constructed transformers permit a combination of the magnetic circuits of such transformers in a manner to form, as it were, a triplicate transformer, having certain advantages which will not here be dealt with. It is evident, however, that the advantages of high-potential transmission may be obtained in this system by transformation, while low or moderate potentials may exist at the dynamos and motors.

In the reconversion of energy of three-phase currents back into power we have the choice of two types of motor: 1st, the reversed three-phase generator which synchronizes in speed perfectly with the generator; 2d, the three-phase non-synchronous motor which changes in speed or requires regulaton for differences of load.

The former requires its field magnets to be excited with continuous currents, and will not necessarily start itself. It will, however, start along with the generator while the latter is starting, if the fields of both be excited strongly and no great load be on the motor machine. The machine is simply a three-phase dynamo reversed, current being delivered to the three connections of the three-branched armature conductor, and the field excited continuously as in the dynamo.

The non-synchronous type of motor becomes, by proper proportioning, practically capable of maintaining a speed which does not vary over a few per cent. from light to full load; it requires no exciting current and starts under load. In construction it is simply a structure in which the rotating field, set up by three currents of a three-branched or suitably arranged conductor in a laminated iron mass called the field, drags around a movable armature carrying a system of closed conductors in which strong currents are set up by the moving lines from the field, which acts to close its magnetic circuit through the armature iron. Thus the rotating bundles of magnetic lines in cutting the armature conductor push such conductor along by virtue of the reaction of the opposing currents set up in the armature conductors or closed circuit. Such motors, not being reversed dynamos, cannot act to generate current if revolved by power. Their great advantage is that they may be placed anywhere where convenient to receive current from the mains direct or from transformers, they may be started or stopped at will and have no commutators. That they may be made quite efficient is evident; that is only a question of proper designing. Both forms of motors mentioned for three-phase currents will doubtless have their uses. While lights may be run from three-phase current systems by transformers, or directly from the mains if the potential be proper, such systems possess no peculiar advantages over the single phase systems except that in the generation of three-phase currents a smoother action of the dynamo is obtained and probably therefore a slightly increased economy, or perhaps a little greater output.

There is another important way in which the three-phase currents may be utilized at the receiving end. They may readily be transformed into continuous currents of low potential or of any potential practicable for commutation. The means for transformation in this case is a motor generator of special construction. It posseses an armature winding and connections suitable for three-phase currents, a field magnet system excited by continuous currents from any suitable source and acting on the armature, a secondary winding on the armature, or the same winding as that connected to the three-phase mains, with the usual numerous connections to the segments of a continuous current commutator, upon which brushes suitably adjusted take off continuous currents. These may be used for lighting, for running continuous current motors, etc. Motor-generators giving 500 volts continuous current, 220 volts and 110 volts, are easily worked from the same system of three-phase mains. The excitation of these machines may be obtained from their own commuted currents, they are self-propelling after having been started along with the generating plant, or may easily be brought to speed before connecting with the three-phase supply by continuous current from another machine in work. They can be compounded for drop of potential in themselves and the lines leading to and from them.

The future supply of electricity in a large city, for all purposes, at any desired voltage of continuous or alternating current, would seem to involve a system about as follows:

A generating station conveniently located for obtaining water for condensing, cheap fuel delivery, and ready disposal of ashes, containing huge triple compound condensing engines driving large dynamos, delivering either directly or through transformation upward high potential three-phase currents a system of high potential mains for three-phase currents, probably consisting of sets of three conductors with a heavy open braid or network covering, tightly woven on, and drawn into an iron pipe filled with insulating oil placed underground to avoid atmospheric disturbances; sub-stations containing compounded three-phase motor-generators feeding into the street mains at the desired potential for lights and continuous current motors; motor-generators feeding currents of suitable potential for street car propulsion; alternating current transformers delivering currents of alternating character at desired voltage for lighting, and for driving commutatorless three-phase motors. There is no electrical service which could not receive its supply from such a system. The time is perhaps not quite ripe for such a comprehensive scheme, but its advantages are obvious to those familiar with the present conditions of supply in large cities.

Time has not permitted the extension of this paper to cover matters of detail, however interesting, and an attempt has simply been made to review in a brief manner the salient points of several systems involving high potential transmission. The purpose of the paper has not been to present any of the history of the growth or development of these various systems touched upon, nor to enter into any of the refinements of theory or practice with such systems, a proper consideration of which question would be very lengthy and consume more space than is at our disposal.

The question may be asked, What are the highest potentials which can ever be made available in electric transmission? Any answer given will necessarily imply foretelling the future practice, a very hazardous thing to attempt. Such answer, may, however, be taken to relate to either a single-phase alternating system or a multiphase, the only difference being in the number of conductors employed. In fact, it is conceivable that the number of conductors in a single-phase system be reduced to one central conductor surrounded by a tube or by several conductors, all enclosed and insulated from a surrounding pipe. Let the pipe be filled with oil and the conductors be separated by being wound with an absorbent net of dry cotton, and let the covering of oil extend over the conductors and be unbroken, practically, over the whole of the high potential conductor, including the fine coils of the transformers at each end of the line, and we have a system in which the employment of very high potentials may become quite feasible. If we provide in the thickness of our oil insulation a sufficient margin of safety from puncture, and so calculate our line that its self-induction and capacity compensate for each other's effects, it would seem that there would be no difficulty from leakage, or from Ferranti effects, as they are called. The condenser effect of the Ferranti cables is large while the self-inductive effects are small. Condenser action tends to accelerate the phase at the dynamo and self-induction retards or lags the phase of the currents and it would seem that by distributing the capacities and self-inductions properly the normal phase without either acceleration or lag could be maintained.

A layer of good insulating oil one inch thick between rounded smooth metal surfaces will equal in resistance to puncturing a potential which will cause a spark in air over 30 inches long. At least the author's tests on this subject point to an approximate relation of 1 to 35 or 40 in dielectric strength between air and good heavy paraffine oil. As nearly as can be estimated, a spark between rounded surfaces at 30 inches in air, represents not less than 500,000 volts and the author's experiments go to show that such potentials can be "kept down," so to speak, in a bath of oil. Whether the condenser effects of a long line would introduce serious difficulties it is impossible to say, but provided that the rate of alternation or periodicity be kept low and the insulation maintained by covering every inch of the high pressure conductors in, say, two inches thick of oil, it might even be possible to work with 500,000 volts. Allowing a loss of only 10 per cent. or 50,000 volts with a double conductor conveying 200 amperes, each conductor having about $\frac{1}{12}$ of a square inch section, a distance of about 240 miles would be covered and the energy carried would be 100,000,000 watts or over 130,000 h. p.

These are striking figures and are only given by way of illustration. They may never be needed to be used in practice, yet the difficulties of realization are less than at first appears; the condenser action of the line being the most serious matter to be dealt with. Such a line is even safer so far as life risks are concerned than an overhead line of much less pressure. In fact it may be said to be practically safe. Any interference with the line is difficult on account of the pipe enclosing it, and on the first weakening of the insulation or before a break in the pipe became complete, a short-circuit of a moderate current would take place and the fuses be blown at the ends of the line. Pipe lines are laid for the conveyance of oil—why should they not be laid for the conveyance of electric energy where it can be done economically? Looked at from the standpoint of very high potentials, Niagara may be said to be gradually approaching the surrounding cities.

"A DAY WITH EDISON AT SCHENECTADY."

A VERY handsome volume of photographic views of the great Edison shops at Schenectady has been prepared by Messrs. W. H. Butler and E. Jones, who are in the service of the Edison General Electric Co. at Schenectady, N. Y. The album is 9 by 11 inches, bound in heavy boards, and contains about 150 photographs, several being artistically grouped on a page. There are a great many portraits, including a group of all the foremen, and individual ones of Messrs. Edison, Insull, Kruesi, Turner, Weber, Parshall and others. Besides these, there are pictures of some 40 or 50 different departments, showing in a very clear and interesting manner just how the work is done. The photographs are all beautifully taken and exceedingly well mounted. The album is one well worth having, and we entertain no doubt that it will be largely in demand. It is to be sold by subscription at $6 each, and all inquiries may be sent to the gentlemen above named. Mr. Butler, who has charge of the work, is a Yale man and one of the students at the works. He has been quick to see the most interesting points and, with the help of Mr. Jones, has turned out a book of unusual interest and value.

LIGHTNING ARRESTERS, AND THE DISCOVERY OF NON-ARCING METALS.[1]

BY ALEXANDER J. WURTS.

DURING thunder storms electric wires become charged from the atmosphere with an electric potential, different from that of the earth; there is then a tendency to establish an equilibrium, that is, for a discharge to or from the earth as the case may be. If this discharge be left to choose its own path, it will select one or many of the weaker points, usually the most vital part of the system, and there rupture the insulation. It therefore becomes necessary to rid the line of this charge in some suitable manner, and without allowing it to damage any portion of the system. This is usually accomplished by the well-known air-gap lightning arrester. Benjamin Franklin, nearly one hundred and fifty years ago, drew sparks across an air gap from a charged conductor very much as we do it to-day. He, however, did this to demonstrate the presence of the charge, while we do it for good riddance.

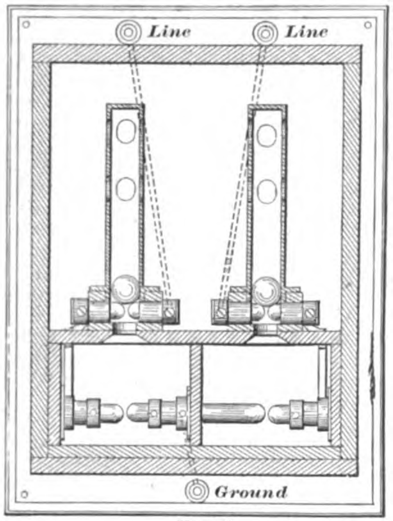

Fig. 1.

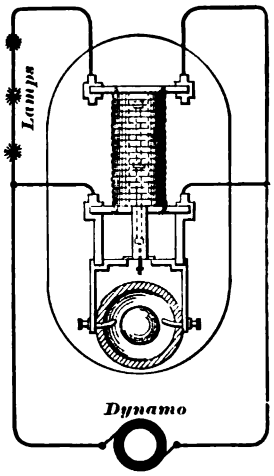

Fig. 2.

Shortly after the erection of the first telegraph line by Morse in 1844, it was found necessary to provide means for discharging the line during thunder storms, and numerous devices were brought out and patented for this purpose. The main features of lightning arresters from that time till recently have been the "spark gap" and the "kicking coil," the latter being interposed between the discharge circuit and the apparatus to be protected. The spark gap arrester on telegraph lines answers the purpose admirably. When, however, electric lighting was introduced, the lightning arrester problem became more difficult in consequence of the dynamo short-circuit that invariably follows the discharge. It then became necessary to provide means for promptly interrupting this short-circuit, and so the fuse was added, and then there followed all kinds of automatic devices for interrupting the short-circuit and restoring the arrester to its normal condition. But most of these devices have been more or less defective and unsatisfactory; and now that high potentials are used, the proper interruption of the short-circuit becomes more difficult than ever. The ideal lightning arrester would be a simple discharge gap of such a character as not to permit a short-circuit of the dynamo, or better yet, metallic connections to the ground without dynamo leakage.

When I first became interested in this subject, I was naturally guided somewhat by previous practice, which had been to provide with each arrester and discharge circuit an automatic circuit interrupter. Fig. 1 illustrates my first practical step in this direction, and represents the Winsor-Wurts lightning arrester, the fundamental idea of which emanated from Mr. Paul Winsor, who proposed that a discharge gap be placed in the neck of a bottle, the idea being that the heat of the arc formed by the short-circuit would sufficiently expand the air in the body of the bottle to blow out the arc. With this idea as a nucleus, the arrester depicted in Fig. 1 was evolved. Referring to the figure, it will be noticed, without going into detail, that the arrester is double-pole and that each discharge gap is placed in the centre of an air chamber. In the upper part of each of these there is a slotted passage, which might correspond to the neck of a bottle, and in which there is placed a second air-gap in series with each of the others. The second air-gap is bridged with a carbon ball, the latter being held in place by tubes having vent holes in the sides and rubber bumpers at the top. The action which takes place when a discharge to ground is made with a resulting short-circuit is as follows: The arc at either or both of the jumping spaces instantly heats and expands the air in the respective air chamber, which, rushing up through the slotted passages, blows either or both carbon balls to the top of the tubes. The arc formed where the circuit has been broken by the projected carbon ball is, at the same time, instantly blown out, thus completely rupturing the circuit. The only demonstration is a quick puff as the air rushes out of the holes near the upper ends of the tubes. The object of the holes is obvious. As the balls are confined in the tubes they at once drop back to their former positions, and thus automatically place the apparatus in a condition ready for another discharge and short-circuit. In testing this arrester the terminals are connected to the circuit of a thousand-volt generator. The air spaces are bridged over with a fine wire to take the place of an actual discharge. Then, by the throw of a switch, the full pressure of the machine is placed on the arrester. There is an enormous rush of current, the temporary wire bridges fuse, arcs are formed, the air expands with an explosion, the balls fly up, more arcs are formed, tongues of fire shoot out of the holes in the tubes, the upper arcs are blown out, the balls drop back to their normal positions, and all this happens like a pistol shot, without causing more than an insignificant flicker in the lamps. It is very curious to notice that if this short-circuit is made on the crest of a wave of an alternating current, the report of the explosion is much sharper and louder than when the circuit is closed at the instant the wave is at or near the neutral point. I might add here that, after short-circuiting a thousand-volt 3,000-light machine through such an arrester about 400 times, there was not the slightest deterioration to be noticed anywhere. Those who are not familiar with this kind of work will hardly appreciate this last fact, or realize what is accomplished each time the arrester "goes off."

Soon after this arrester was completed, steps were taken to adapt the same principle to an arc circuit lightning arrester, which resulted in the one illustrated in Fig. 2. By referring to the figure, you will notice that a vertical solenoid provided with an iron core is connected in the main circuit beyond the point of contact with the discharge circuit. The discharge electrodes are curved arms which swing freely through the sides of a cylindrical air chamber, and the construction is such that when the core falls, the discharge electrodes will be forced out. The action is then as follows: Under normal running conditions the core is held up in the solenoid, but if a discharge occurs from both sides at once, short-circuiting the machine through the discharge points, the solenoid will at once lose its power, the core will fall and force the discharge arms out through the holes in the walls of the chamber. This action would draw out arcs three inches long, and the heat thus generated is sufficient to cause a sudden expansion of air in the air chamber and thus blow out the arcs even though the current be but ten amperes and the pressure 3,000 volts. Without the device just described for lengthening the arc, the heat developed would have been insufficient. In short-circuiting a 50-light machine through this arrester, there is a scarcely perceptible flicker in the lamps, the core drops, the short-circuit is opened and the core drawn back into its normal position ready for further action, all in an instant of time. Although I have used an electromagnetic device in the construction of this type of arrester, it will be noticed that the placing of a coil in the lightning arrester circuit has been avoided, so that even though every discharge has to pass through this coil to reach the discharge points, yet from this point on, the discharge has a non-

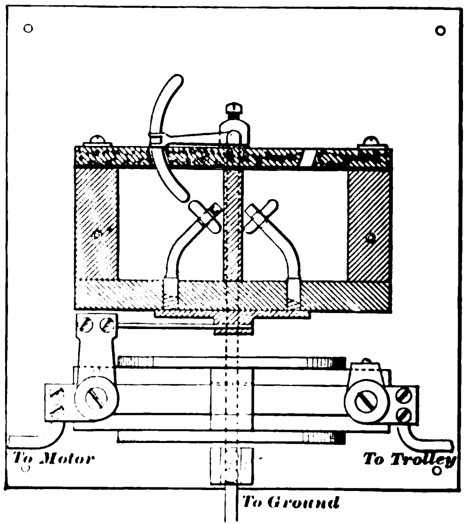

Fig. 3.

---

[1] A paper read before the American Institute of Electrical Engineers, New York, March 15th, 1892.

inductive path to earth through the arrester in preference to the dynamo.

Neither of these arresters would interrupt a short-circuit on a 500-volt direct current generator, so after some futher experimenting the arrester shown in Fig. 3 was evolved. Referring to Fig. 3, it will be noticed that there are two air chambers, in each of which is a fixed carbon discharge point. Above these chambers is a curved carbon swinging freely from one chamber to the other through suitable openings, so that either end of the curved carbon, as the case may be, shall come into close proximity to either of the fixed discharge points. The action is as follows: When a discharge takes place, it passes to one of the fixed discharge points, depending upon the position of the curved carbon, then across the air space to the curved carbon, and from there to the ground, as shown in the figure. The dynamo current then following, causes an arc to be established between the curved carbon and one of the fixed points, and the heat generated by this arc expands the air in its respective chamber, increasing the pressure therein, and causing the curved carbon to be instantly blown from one chamber to the other. This ruptures the arc and adjusts the arrester for the next discharge. In testing this arrester, 500-volt and 1,000-volt generators have been repeatedly short-circuited through it, and in every case the circuit has been instantly broken without injury to the dynamo, and the arrester has as quickly reset itself in readiness for future use. In one of the tests made to demonstrate its promptness and reliability, the fixed points were so adjusted as to touch the curved carbon in either of its two normal positions. A 1,000-volt generator was then short-circuited through the arrester, which resulted in the circuit being repeatedly opened and closed without injury to either dynamo or arrester. This power circuit arrester was afterwards much improved, and finally took the form shown in Fig. 4, and the arrester shown in Fig. 1 was also finally changed to this form. This arrester is made of iron and marble, and its advantages over the others are its non-combustibility and the double break in connection with the air blast. Fig. 5 illustrates the same arrester, fitted into an iron box lined with asbestos, and in this shape is adapted to either car or pole use.

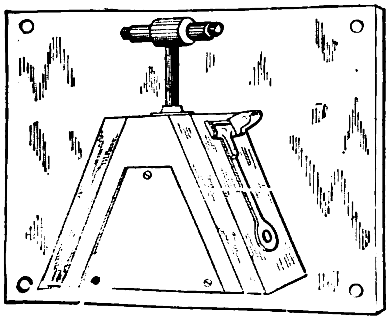

Fig. 4.

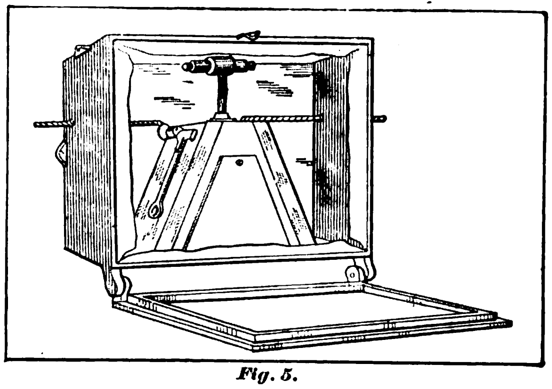

Fig. 5.

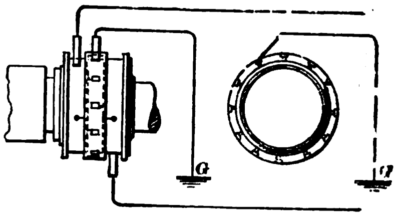

Fig. 6.

So far you will observe that my one object had been to provide a simple, reliable and non-inductive circuit interrupter. In this I had succeeded as far as immediate wants were concerned, but with the prospects of higher voltages in the near future the problem seemed but imperfectly solved. The experiments of Lodge, Hughes and others were carefully studied, and I finally decided that it might be well to repeat some of them. So, one day, while casting about for some suitable means of experimenting, I happened to be passing under a driving belt; my hair stood on end, and my body became charged. Of course somebody had to touch my ear (that seems to be the proper thing to do under the circumstances), and my body became discharged. That evening, while thinking over the events of the day, my thoughts rested on this belt, the electrified atmosphere around it, and the charging and discharging of my body, and I wondered whether the phenomena observed were not very similar to those experienced during thunder storms. On the following day I stretched about four feet of No. 14 insulated wire under a belt, parallel to it, and about two inches below it. I then brought the ends to a convenient place where I could ground the wire, or not, as I chose. The room was then darkened, the belt set in motion, and a most beautiful sight presented itself. Between the belt and the wire were seen soft purple streamers, giving the appearance of a film connecting the belt and wire. In some places these streamers were more dense than others, and in this were suggestive of the Northern Lights. There was no disruptive discharge at all between the belt and wire. On bringing the bare end of the wire within one-quarter of an inch of a ground a continuous discharge took place. When one end was well grounded no spark could be drawn from the other end. When one end was grounded through a choke coil consisting of about 40 turns of No. 14 wire, small sparks could be drawn from the other end, showing the impedance offered by the coils to the discharge. When neither end was grounded, both ends showed "side flash" every two or three seconds. So far, these results seemed to correspond with the experience met with in electric systems when exposed to the influence of thunder storms. The conditions also seemed to be very similar. Here was a wire stretched through an electrically disturbed atmosphere; the wire became charged, and the charge passed readily to ground through a metallic discharge circuit containing an air gap. An induction coil impeded the discharge, and when there was no ground connection there was side flash. All these results seemed to correspond with practice.

The thought then occurred to me, "What would happen if I were to string a second wire near and a parallel to the first, and ground it, leaving the first wire insulated?" A second wire was quickly strung, but before making the ground connection the following observations were made. The purple streamers seemed equally divided between the first and second wires, and either would give about equal sparks. On grounding the second wire no indication of a charge on the other could be obtained. The streamers were now all directed to the second wire, and the first was as inert as a block of stone would have been. If, now, in these laboratory experiments, there were reproduced the conditions existing between electric wires and the atmosphere during thunder storms, then, to prevent wires from becoming charged, all that would be necessary would be to stretch a grounded wire near and parallel with the wire to be protected, and, in fact, it would seem as though one such grounded wire would protect all the wires that could be strung on any one line of poles. An explanation of these phenomena is not far to seek. An insulated wire lying on the surface of the earth cannot become charged from the atmosphere, because the latter is at the same potential as the earth; but an insulated pole line can be, and is charged when exposed to the influence of thunder storms, because the atmosphere surrounding the wire is at a different potential from the earth; therefore with an insulated pole line, and an adjacent grounded parallel wire, the grounded wire in effect transfers the earth to the level of such wires, but if a grounded wire near and parallel to an insulated wire in effect causes the earth to be transferred to the level of the insulated wire, then the insulated wire cannot become charged. The grounded wire running over the poles will relieve the atmosphere in its neighborhood of any difference of electric potential that would otherwise exist between that neighboring atmosphere and the earth, and the insulated line would then fail to become charged. Soon after performing this experiment, I learned that such an overhead grounded wire had been used to great advantage, and that being the case was greatly surprised that it was not in more general use.

I next replaced the wire I was using, which was much battered and bruised, with a new wire, and found the charge much diminished by the superior insulation. The latter was then replaced by bare wire insulated with a glass tube. The spark now was scarcely perceptible, being about the size of the spark obtained from a Leclanché cell, and even this could be obtained only after several minutes of charging. These results seemed to indicate a gradual charging of the wire by more or less perfect contact with an atmosphere having a different potential from that of the earth. With the idea of gradual charging in mind, the following plan was hit upon for a lightning arrester. The first conception was to alternately ground both poles of a generator over a very small air-gap, and at rapidly recurring intervals. The improved plan, however, was to alternately dead ground the poles of an alternator at every neutral point in the electromotive force wave, the idea being to so constantly discharge the line in this manner, as to effectually prevent a charge from attaining any considerable intensity, and at the same time avoid the short-circuit which now invariably follows the discharge over the air gap of our present arresters. The method of carrying out this plan will be understood by a glance at Fig. 6. Upon experimenting, I found that an alternator could be short-circuited at the neutral point without a spark. If the short-circuit occurred a little before the neutral point, that is, on a decreasing electromotive force, there was slight sparking, but no tendency to hold on. If the short-circuit occurred at all after the neutral point, a furious arc was established which would hold on indefinitely.

This form of arrester has not yet been tested in actual practice, but it will be during the coming season, and I have great hopes that it will not only successfully discharge the line, but effectually prevent any considerable accumulation of the charge. Of course this form of arrester is only adapted to alternators.

For direct current use I have devised something quite similar, the principle of which will be understood by reference to Fig. 7.

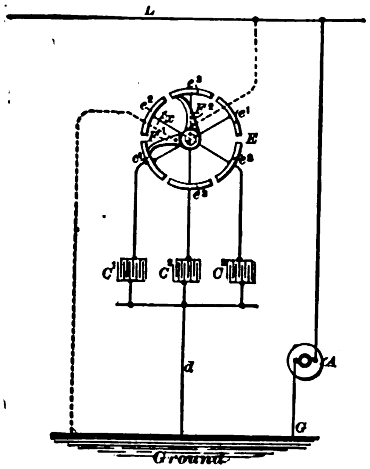

Fig. 7.

Referring to the figure, A is a generator, one pole of which is grounded at G, the other being connected to the trolley line L; E is a circuit controlling device consisting of fixed commutator-like metal pieces e^1, e^2, e^3, opposite pieces being electrically connected; F^1, F^2, are brushes insulated from each other and revolving at a high speed in a direction indicated by the arrow; F^1, is connected to earth, and F^2, to the line; e^1, e^2, e^3, are connected respectively to three condensers, C^1, C^2, C^3, the latter being grounded as indicated at *d*. The action is as follows: With the brushes in their present positions, the line is connected through F^2 and e^2 to condenser C^2. This condenser is therefore being charged while condenser C^1 is being discharged to earth through e^1 F^1. When F^2 passes to e^1, condenser C^1 will be connected to the line, and become charged while condenser C^2 will be discharging through e^2 and F^1. Thus by the continued rotation of these two brushes, it will be seen that the trolley line is being constantly discharged into a fresh condenser.

This arrester has also not been tested in actual practice, but if my hopes are fulfilled it will accomplish for direct current circuits what the neutral point arrester is intended to accomplish for alternating circuits, the idea being in either case to take off the charge bit by bit, but at such rapidly recurring intervals that the line will be kept practically free from charge, or, at least prevent the charge from obtaining sufficient intensity to damage any portion of the system. Personally I am much interested in these two arresters, which practically afford direct connection to earth without dynamo leakage, and would like to dwell on them more in detail, but time will not permit.

Referring once more to my experiments with charged wires, I would say that they were nearly all repetitions of experiments quite familiar to all of you. Let me, however, call your attention to one of them which I am confident is not old in detail. Referring to Fig. 8, L is a Leyden jar, *l* is a bare line wire, a portion of which is coiled and immersed in a tank K of water. This tank is well grounded. Line *l* is continued through induction coil C and then grounded as shown; *b* is a gap discharge circuit. Now with a spark at A there was a small spark at *b*; with a gap at *d* there was sparking at *d* and *b*, spark *d* being larger than *b*. With a gap at *e* sparks were obtained simultaneously at *d*, *b*, and *e*. Induction coil C was either a primary or a secondary of a 40-light converter. When C was primary, spark *e* was very small. When C was secondary, *e* was larger, but still small when compared with *d* and *b*. From these experiments I learned two lessons, both of them old, but in books they did not impress me as they did in practice. The first lesson was, that I must not expect one or two discharge circuits to discharge the many miles of wire that we have in our lighting and power circuits. The second was that a "kicking coil," no matter how great its impedance, would still take a portion of the discharge. My final conclusions then were. That in order to afford the best possible protection for electric plants, the wires must fairly bristle with discharge points properly located in discharge circuits. With this idea in mind a cheap and effective pole arrester seemed to be the proper thing to look for. My experiments from this time on led me to a discovery so remarkable, and so contrary to all previous ideas, that I am going to read you a description of them.

In designing the arresters already described, I had followed closely the rut of previous practice, which had always been to provide with each discharge circuit, a circuit-interrupting device. Upon reflection, however, it was evident that one circuit interrupter placed in the main circuit would interrupt the arc on any discharge circuit. For a moment the problem of a simple pole arrester seemed solved, but on second thought the difficulties and inconveniences inseparable from any automatic main circuit interrupter appeared to be insurmountable, and the idea was no sooner conceived than it was abandoned. And yet, poor as it was for practical purposes, it proved a good stepping stone, and led to the following plan, viz.: To provide the line with ordinary discharge circuits, that is, with the well-known saw-tooth protectors, made of carbon so that they would not easily burn away; and then in the station, between the generator and the first discharge circuit, provide an automatic device which, upon the passage of an abnormal current from the generator, would instantly short-circuit the dynamo and as quickly open again, the intention being that should a short-circuit occur out on the line through any of the discharge circuits, a short-circuit at the dynamo would so reduce the pressure on the line as to render it impossible for an arc to maintain itself. Then, any such arc having been extinguished, the short-circuit at the generator could be interrupted, and the service would continue as before. This idea meeting with general approval, steps were at once taken to put it to a test in the following manner: To a 1,000-volt alternator there was connected a circuit consisting of about 100 yards of line wire, and in this circuit there was placed a pair of carbon dischargers having saw-tooth edges, and a $\frac{1}{16}$ in. air-gap, also a switch. In shunt with this circuit, that is, directly across the terminals of the generator, there was connected a simple device (it will not be necessary to explain its construction) which, upon the passage of an abnormal current in the circuit containing the discharges, would instantly short-circuit the generator and as quickly open again. All the connections being made, the air-gap was bridged with a bit of tinfoil to start the arc, and the switch thrown. The actions that followed in an unconceivably short space of time were these: The tinfoil burst with a snap, an arc was formed, the automatic short-circuiting device operated, the arc was extinguished and the short-circuiting device opened. So far, this was exactly what was anticipated, but no sooner had the short-circuiting device opened, and the electromotive force returned to the line and the dischargers, than the dynamo pressure forced an arc across the air-gap once more, and the whole operation was repeated. This repetition was found to be due to the fact that when the arc was first established between the carbon saw-tooth plates, the carbons were heated to a white heat which, not having time to dissipate itself before the pressure returned, the dynamo current found a sufficiently easy path over the heated air-gap to re-establish an arc. However, the test being otherwise satisfactory, success seemed assured, for all that was necessary now was to use solid metal discharges that would readily conduct the heat away, and the trouble above cited would no doubt be avoided. So the test was repeated, using the same apparatus as before, except the dischargers, which now consisted of three solid, round, brass rods, 1 in. in diameter and $1\frac{1}{4}$ in. long, placed side by side with their axes parallel to each other, and having air-gaps of $\frac{1}{16}$ in. That is, the line was connected to the two outside bars, leaving the middle one idle to be connected to ground, as would be the case in a double-pole lightning arrester. The air-gaps were bridged as before with tinfoil to start the arc, and the switch thrown. The test was successful in the highest degree—too successful, in fact, not to arouse suspicion. So I thought I would repeat the experiment, and see how the dischargers would behave without the short circuiting device. The result was an overwhelming surprise, for at the dischargers there was merely an insignificant spark scarcely larger than a pea. The experiment was tried again and again, with the same result. Any electrician would have predicted a brilliant display of fireworks. The most plausible theory advanced to explain this action was that the electric motor driving the dynamo being small, its speed was

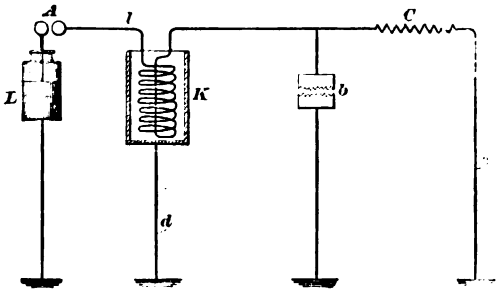

Fig. 8.

probably reduced to such an extent by the overload suddenly thrown upon it, that the electric pressure was at once reduced below that which would be necessary to maintain an arc across the air-gaps. On second thought, this theory would have seemed improbable, but at the time it was accepted without a question. In a few days a test was again made, this time a small engine being used for motive power, and the same results were obtained as before. The afternoon of the same day both engine and generator were changed, with like results. In the meantime a little reflection seemed to indicate that perhaps this strange action was not, after all, due to the slowing down of the motor, but to the possible cooling effect of the metal dischargers on the arc. With this idea in mind, I had constructed, a set of three dischargers similar to the first, but much larger, 2½ in. diameter x 3 in. long, thinking that if a little metal was good, more would be better, and that perhaps with a large generator the mass of metal would have to be greatly increased to produce the results already obtained. This large discharger was connected to a 3,000-light, 1,000-volt alternator; the air spaces were bridged as before; and the scene which followed beggars description. The large metal bars were melted like beeswax in a great ball of fire. My disappointment was keen, for I thought I was on the verge of making a discovery, and that in the previous cases the comparatively feeble engine had not been the cause of the action. Thinking, however, there could be no harm in melting up the smaller discharger, I connected it in where the larger one had been, bridged the air space, and threw in the switch. Imagine my astonishment on hearing an insignificant snap like the crack of a toy pistol, and seeing an arc as before no larger than a pea. I then pushed a nickel down into one of the air-gaps to short-circuit it, and leave only one air-gap for the arc, and tested again, with the same results. Two questions now presented themselves: viz., what were the differences between the large and small dischargers other than the size, and why did the small discharger behave in this altogether unlooked-for manner? The answer to the first question was readily found by tracing the two dischargers back to their source, and there learning that the larger one of the two was made of cast brass, containing certain proportions of tin and copper, and that the smaller one was made of hard drawn brass, containing certain proportions of zinc and copper. These facts at once established two differences between the dischargers other than mere size: one was, their physical structure, the other their composition. Which of these two differences caused the difference in their actions? A discharger composed of cast brass containing the same proportions of zinc and copper as the hard drawn brass discharger was made and tested, and found to work perfectly. It was thus determined that the physical structure of the metal had no influence in suppressing the arc. The important difference between the two dischargers then lay probably in their composition, and I was now rapidly becoming convinced that in brass, consisting of certain proportions of copper and zinc, there must exist certain properties which do not permit of an arc being maintained between two dischargers, even with the high pressures of 1,000 volts.

It also occurred to me that possibly the shape of the dischargers had something to do with the results obtained. So the next step taken was to have a number of dischargers made up in different shapes and sizes, such as spheres, ovals, solid half cylinders, tubes and cubes; all worked well with the exception of the cubes. The cubes were placed so that their faces were separated by $\frac{1}{16}$ in. Now when the tinfoil was placed over their edges, their action was favorable, but if the tinfoil were pushed down between the faces, the arc would hold on indefinitely, and yet without any demonstration whatever, thus, even when the arc did hold on, showing a very different action from the other metals. The size of the dischargers did not seem to affect the results so long as there was sufficient metal to prevent actual melting—¼ in. brass rod melted on the third trial.

It was next decided to make dischargers of other metals, and thus learn whether there were any other substances that would give these results, and if so, perhaps some light would be thrown on the real cause of the action. The metals first tested were hard steel, hard-drawn copper, phosphor-bronze, aluminum-bronze and aluminum, all of which failed utterly. The next metal tested was zinc, and with this, most successful results were obtained. Perhaps you will now think the experimenter very slow to put two and two together, but who is there who is at all familiar with the properties of zinc, that would have suggested this metal as one likely to resist an electric arc and 1,000 volts in this manner? With such results before me, I was ready to try anything. The next metals were tin and nickel. Both of these failed. Tin made the most brilliant display of all the metals. The next tried was antimony, and it worked perfectly. The theory now advanced to explain the phenomena was that with the metals that do not allow the arc to be maintained, there is formed at the instant the arc is started, an oxide of the metal which, becoming instantly volatilized in the intense heat of the arc, chokes up the air-gap with vapors of high resistance, and so presents an effective barrier to the further passage of the current. With metals that do maintain the arc, instead of the vapor of the oxide of the metal, there is formed a pure vapor of the metal itself, and this offers comparatively no resistance to the passage of the current. When tests similar to the above were made on a 500-volt direct current generator, every one of the metals failed. The arc, however, was small and quiet with the special metals, thus even with the direct current showing a very peculiar action. Another curious phenomenon connected with zinc and antimony is this: The smaller the air-gap, the less tendency there is to maintain an arc when using an alternating current at 1,000 volts pressure. In fact, when the air-gap is two inches long the arc, when once started, will be maintained, while at ½ in. or ¼ in. the arc will not give up without a struggle, and at $\frac{1}{32}$ in. there is only a small spark caused by the fusing of the tinfoil, and the circuit is instantly interrupted.

The next step taken was to try higher pressures. A short circuit on a 2,000-volt generator, through the double air-gap discharger, failed to be interrupted; four and five air spaces also failed. Six air spaces of $\frac{1}{32}$ in. each, interrupted the short circuit instantly, but six air spaces, which would make three on each side of the circuit for the lightning charge to jump through, were strongly objected to as offering too great a resistance. A test was then made to determine the pressure needed to strike an arc across three air-gaps, and was found to be 3,500 volts, measured with a Cardew on an alternating current generator. The experimenter then procured a lightning arrester well known in the market, and one which is known to take the lightning discharge successfully, and tested it for the striking electromotive force, which was found to be between 8,000 and 9,000 volts. In order, however, to avoid any prejudice that a series of air-gaps might arouse, the following plan was hit upon: Pairs of non-arcing dischargers were mounted upon thermostatic supports in such a manner that the pairs would normally rest in contact with each other, and so that any current traversing the system would be forced to pass through the thermostats and dischargers in series. The thermostats were so arranged as to cause the two dischargers in each pair to open a way from each other upon the passage of the current. If then, a single and permanent air-gap were connected in series with this system, that is, an air-gap just sufficient to prevent the normal pressure of the line from striking an arc, and if an arc were started across it, the sudden rush of current through the thermostats would instantly introduce a number of air-gaps in the circuit corresponding to the number of pairs of thermostatic dischargers, and thus automatically open the short-circuit. This device was tested and found to work admirably. Of course after the circuit has been interrupted, the thermostatic dischargers at once return to their normal positions. In fact, this action is so rapid that if a series of these dischargers be connected in a short-circuit without a permanent air-gap, the circuit will be automatically opened and closed every two or three seconds. In order to appreciate the very remarkable action of this thermostatic device it must be well borne in mind that a very small air-gap is all that is necessary for the interruption of the circuit.

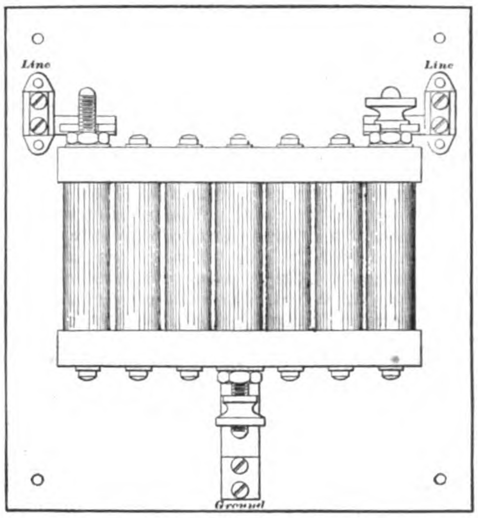

Fig. 9.

Thus far, although I had tested a number of metals, my selection had been quite at random, so that by this time I was desirous of making a more thorough and systematic investigation of this new property. The chemical properties of zinc and antimony were carefully compared without any new light. The various groups of metals were examined, and then it occurred to me that, of all the metals tested, not one of them belonged to the two groups in which zinc and antimony are found, according to Mendeljeff's grouping. The metals of the zinc group are,—zinc, cadmium, mercury and magnesium, and of the antimony group are,—antimony, bismuth, phosphorus, and arsenic. I first tested cadmium, and found it non-arcing. Then magnesium,—more, however, from a sense of duty than because I had hopes of anything but negative results. Fortunately I made this test on much lower E. M. F.'S, and found it non-arcing at 100 volts over two air-gaps of $\frac{1}{32}$ in. each. On 250 volts the magnesium caught fire, which was, of course anticipated. I then wanted to try mercury, but for the moment, not seeing how to make such a test with a liquid, I was diverted to the antimony group, and upon testing bismuth found it to be non-arcing. Phosphorus and arsenic were not tested. A final attack was now made upon the zinc group by testing mercury in the form of a copper amalgam. This test was the most successful one of all, for after a number of short-circuits on a 1,000-volt alternator, I found the surface of my dischargers had not been disturbed in the slightest degree. It will thus be seen that all available metals in these two groups are non-arcing. In searching for the non-arcing metals each test was made with two air-gaps and the E. M. F. at the time of the short-circuit was, with the exception of the test on magnesium, 1,000 volts.

Fig. 9 represents a double-pole lightning arrester made of non-arcing metal, and in connection with this paper will be readily understood without further explanation.

A TEN THOUSAND VOLT TRANSMISSION IN CALIFORNIA.

IT is reported from California that the San Antonio Light & Power Co., of Pomona, Cal., have closed a contract with the Westinghouse Electric & Mfg. Co. of Pittsburgh for a unique long-distance plant for electric light and power transmission. The power plant will be located, it is said, in the San Antonio cañon about 15 miles distant from Pomona. At this point is a fall of some 425 feet with a minimum flow of water of about 1,300 cubic feet per minute, or approximately 1,000 hydraulic horse power. This water-power will be somewhat expensive to develop as it is necessary to build a tunnel 1,300 feet long through a spur of San Antonio peak which is practically of solid rock.

From the lower end of this tunnel a steel pipe line from 2,000 to 2,500 feet in length will be constructed to convey the water down the mountain to the power house. For transforming this power into mechanical motion, Pelton wheels provided with deflecting nozzle governors will be employed. These wheels will be connected by means of an insulated coupling direct with the dynamos, no belts whatever being used in the plant. Special slow speed alternators will be installed, each machine having a capacity of 120 K. W. and driven at a speed of 660 r. p. m. Only two exciters will be utilized for the entire plant, these being driven direct by small independent Pelton wheels furnished with governors similar to those used on the large wheels driving the alternators. On account of the excessively high water pressure great precautions will be taken to provide suitable relief valves and cushions to take up the destructive water hammer effects should it ever become necessary to shut off the water. Under ordinary conditions, however, when it is desired to stop a dynamo, the nozzle will be deflected so that the stream passes clear of the wheel. The dynamos will generate their current at an electromotive force of about 1,000 volts. From the dynamos the current will be led to a switchboard of the high class marble panel type in general use by these manufacturers in their large installations.

All the switchboard instruments used throughout the entire plant, which will be completely equipped in this particular, will be marble mounted. From the switchboard the current will be conveyed to raising transformers which will increase the pressure to 10,000 volts. The lines between the power house and the towns which it is proposed to illuminate will be built of naked, hard-drawn copper wire, supported on fluid insulators. There will be two principal sub-stations, the first located in Pomona, 15 miles by the line from the generating plant, and the second in San Bernardino, 30 miles by the wire from the station. In these sub-stations the voltage will be reduced by means of transformers exactly similar to those used at the main generating power house to 1,000 and 2,000 volts; the 1,000 volt system is intended to be used to feed the lights in Pomona and San Bernardino. From the Pomona sub-station 2,000 volt lines will probably be run to Ontario, Claremont and Lordsburg. From San Bernardino a 2,000 volt line will in all likelihood be run to Colton. In the sub-station regulators will be furnished, by means of which the sub-station attendant can regulate the voltage of the distributing circuits independently of the generating plant. To effect this the Stillwell regulator, manufactured by the Westinghouse Co., will be used. All necessity for pressure wires upon the 10,000, 1,000 or 2,000 volt systems will be obviated by the use of an ingenious device known as the compensator.

The voltage used upon the incandescent lamps fed by this system will be uniformly 100 volts. Several motors will probably be employed and they will be of the Westinghouse synchronous type.

The insulators will probably be of the same pattern as those used upon the Frankfort-Lauffen installation with either double or triple oil receptacles.

The San Antonio Co. have tributary to their plant some twenty five or thirty thousand people located in a half dozen prosperous towns, and as gas and oil are exceedingly high, there is little doubt but that a large volume of business will be found. Coal is also very expensive in Southern California so that a considerable power business can be reasonably expected. This company has also several other good water-powers located upon the stream which they will develop as the demand requires.

Taken all in all, this plant is by far the highest tension and longest distributing system ever attempted in this country and perhaps it might be said ever attempted commercially in the electrical business.

The longest transmission plant for incandescent lighting previous to this in America is the one at Portland, Oregon. The power there is located on the Willamette Falls, about 15 miles from the city. The machinery is of the same manufacture as that which will be used at Pomona. Current for several thousand incandescent lamps is generated at a pressure of 5,000 volts, and transmitted at that tension to the sub-station in Portland where the voltage is reduced to 1,000 for distribution. The switchboard and regulators used at Portland are identical with those that will be installed in the sub-stations at Pomona and San Bernardino.

The dynamos in Portland are of the peculiar toothed armature form made by the Westinghouse Co. and similar ones will be employed at Pomona. Although the tension generated by the dynamos at Portland is exceedingly high, it is reported that only one armature coil has ever given out there in something like two years' operation, and as a coil can be replaced in a few minutes, this is certainly not serious.

All the machinery and devices used upon the San Antonio Co.'s plant will be furnished by the Westinghouse Co. which is a guarantee for the successful operation of the system. The plant will be installed by the local company under the direct supervision of the manufacturers, and none but the very best material will be used in the work. This plant will form one of the most important achievements in electrical transmission and is destined to be followed by numerous similar distribution systems.

College Notes.

COLUMBIA COLLEGE.

BY the action of the faculty and trustees of Columbia College, Mr. F. B. Crocker, who has had charge of the instruction in electrical work since the special electrical course was established, has now been appointed Adjunct Professor of Electrical Engineering. The actual position remains the same, and the course is continued in the Engineering Department, with Prof. Trowbridge as its head.

Personal.

MR. R. MCCARTHY, for many years at the head of the bookkeeping department of *The Electrical World*, has severed his connection with that institution. He will now devote his attention to expert accounting for which his experience and fidelity give him superior qualifications. His familiarity with electrical matters also recommends him strongly to electrical companies and concerns. Mr. McCarthy has opened offices at 114 Nassau street, this city.

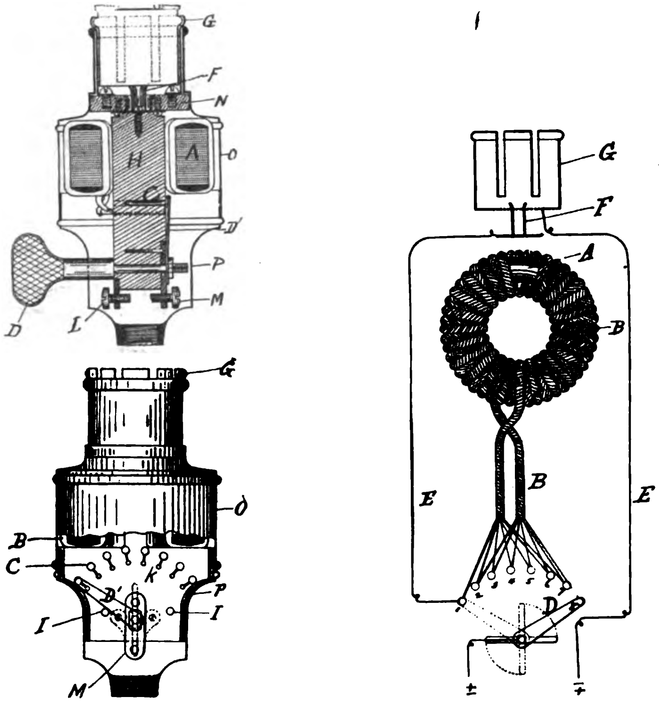
Patent Notes.

THE RIES REGULATING SOCKET.

THE recent issue of patent No. 470,402, March 8, 1892 regulating socket holder for incandescent lamp, to Elias E. Ries and W. S. Horry, and assigned to the Ries Electric Specialty Co., of Baltimore, covering some of the later features of their new regulating socket, enables us to place before our readers a detailed description of the socket that will show how the regulation of the light is effected, and how admirably the socket is adapted to the purpose for which it has been designed. The accompanying illustrations explain the construction of the socket. Fig. 1 is a sectional elevation, Fig. 2 a side elevation with part of enclosing shell broken away, and Fig. 3 a diagram view showing the coil and circuit connections.

As will be seen, the socket comprises a finely laminated iron ring A, wrapped at one operation with a cable, B, composed of a number of well-insulated copper wires, the ends of which are brought to a row of contact pins, C, arranged in the path of an arm, D, connected to the operating key, in such a manner that all of the wires of the cable are, by means of these pins, connected in series with each other and with the lamp. The coil thus formed is mounted upon an insulating block H, contained within the enclosing shell, to which block are likewise secured the lamp-holding contacts, the operating key and the binding screws L M to which the leading-in wires are attached.

The amount of counter E. M. F. force generated by this socket varies according to the position of the operating key and its arm. The coil is so arranged that when the arm D′ is removed from its open-circuit position at the extreme right and rests upon contact No. 7, Fig. 3, all of the winding B is in circuit with the lamp. In this position the counter E. M. F. generated by the coil is greatest, so that only a small portion of the applied E. M. F., sufficient to just render the lamp filament visible in the dark, is permitted to pass to the lamp. As the arm D′ is moved toward the left over the series of contact pins C, it cuts out successive sections of the winding B, thereby reducing the length of wire subjected to the inductive action of the core A, and correspondingly increasing the amount of light given by the lamp, until when the arm finally rests upon contact No. 1, practically all of the coil sections are cut out and the lamp burns at its greatest brilliancy. In some cases the coil is arranged to generate a counter E. M. F. that is nominally almost equal to and balances the direct E. M. F.; in which case the light is extinguished without the necessity of opening the circuit in which it is placed. This latter arrangement practically introduces a new system of electric lighting in which the lamp filament is at all times subjected to two opposing electromotive forces, one being variable with respect to the other, the light produced being due to the difference of potential between the two electromotive forces as determined by the position of the operating key of the socket.



FIGS. 1, 2 AND 3.—THE RIES REGULATING SOCKET.

The construction of the socket is such that it will take lamps of any voltage up to the normal voltage of the supply circuit, or of any candle power up to its rated capacity, and at the same time regulate the brilliancy of the lamp from a fraction of a single candle power up to the full capacity of the lamp, the current not used in the production of light being returned to the circuit, instead of being wasted in the development of heat as occurs when resistances are used for controlling the flow of current to the lamp or other translating device.

The patent just issued relates more particularly to the peculiar winding employed, and is in the nature of an improvement upon certain generic inventions of Mr. Elias E. Ries, for which patent applications are pending, and relating to the same subject. A number of modifications are described involving the use of special methods of construction.

A DEPREZ-CARPENTIER PATENT ON ALTERNATE CURRENT DISTRIBUTION.

ON March 15, 1892, a patent was issued to Marcel Deprez, as assignee of himself and Jules Carpentier, of Paris, for Improvements in Transmission of Electrical Energy. The claims of this patent are of the broadest possible character, and cover in terms every method of electrical distribution for electric lighting and power now in practical use in which alternating currents and transformers are employed in any way. The patent has four claims, but the nature and scope of the patent are perhaps sufficiently set forth in the fourth claim, which reads as follows:

> "The improvement in the art of transmitting electrical energy to and utilizing it at a distance from its source, which consists in generating *maintained and practically uniform* alternating currents of high tension at one station, and sending the same over a line of conductors to another station, generating maintained and practically uniform alternating currents of lower tension at the second station by the inductive influence of the high-tension currents, and converting these maintained low-tension alternating currents into other forms of energy, such as heat, light, etc., substantially as described."

The issue of this patent is the result of a decision rendered by Commissioner Mitchell on July 31, 1891, in reference to an interference which had been pending for some years between the applications of Deprez and Carpentier, Alexander Bernstein and Rudolph M. Hunter, and the well-known Westinghouse patent of Gaulard & Gibbs. Deprez and Carpentier relied for their date upon a disclosure of their invention contained in a French patent (No. 142,140 of April 5, 1881), and the decision of Commissioner Mitchell was to the effect that if their invention, when limited to what was set forth in the French patent, contained any subject-matter patentable over the prior art, their right to a patent could be in no way affected by the patent subsequently issued to Gaulard & Gibbs. Presumably, therefore, the examiners of the Patent Office have reached the conclusion that the subject-matter of the present patent contains nothing not disclosed in the French patent of April 5, 1881, and that there was nothing known in the art at that date anticipating the claims.

In our issue of September 30, 1891 (Vol. XII, p. 386), we referred to a patent which had just been granted to R. M. Hunter for the method of transmitting electric energy, consisting in generating by induction currents of low intensity, converting them by induction into currents of high intensity, transmitting these over a line to a distant point, and reconverting them by induction into currents of low intensity. It will be observed that this patent of Hunter does not cover the method of alternating distribution in ordinary use, but only a particular special application of it, which has been made with success at the Frankfort Exhibition and elsewhere, in the transmission of power to a distance. The present patent covers much broader ground than this, inasmuch as it specifically embraces the generation of high tension currents by any means whatever, whether direct, as is now done in the alternating lighting systems, or by means of a step-up transformer as used in power transmission.

It will be a matter of much speculation in electrical circles as to what view the courts are likely to take of this patent. The apparatus shown and described by Deprez and Carpentier comprises, at the transmitting end, an ordinary Page induction-coil actuated by a battery and a vibrating electromagnetic circuit breaker, while the apparatus at the receiving end consists of a similar induction coil with its connections reversed, and having in its thick-wire circuit a piece of incandescent platinum wire, being the organization described in the French patent. It scarcely needs to be said that such an apparatus does not possess the slightest practical utility for any commercial purpose to-day except, possibly, as a gas-lighter. Under the provisions of our patent law, this patent, in any event, must expire at the end of fourteen years from the date of the French patent, which will be on April 5, 1895. We note another somewhat singular circumstance in connection with this patent. The United States statute provides that no patent can be granted for an invention which has been more than two years in public use. The first electric lighting plant on the alternating system put in commercial operation in this country was that of the Westinghouse Company in Buffalo, which to the best of our recollection started on the 30th of November, 1886. The application for the patent of Deprez and Carpentier was filed November 27, 1888, thus narrowly missing, by three days, being barred by the statutory limitation relating to public use. Another interesting point arises in connection with the French patent of Maiche for a system of telegraphy, dated September 15, 1880, some six months prior to Deprez and Carpentier's French patent, relied on as the date of their invention, in which precisely the same combination of circuits and apparatus is applied to telegraphic purposes, being adapted thereto by the addition of a key in the primary circuit at the transmitting station, by which the continuous series of vibrations is broken up into dots and dashes for Morse transmission. The anticipatory effect of Maiche's patent is apparently avoided in the Deprez claim, by the insertion of the qualifying words "maintained and practically uniform alternating currents," but whether this qualification will suffice to make the claim tenable remains to be seen.

It is understood that this patent is owned by a powerful syndicate of European capitalists, and if this is really the case, further interesting developments may doubtless be looked for at no distant date.

MR. FREDERIC NICHOLLS, of Toronto, delivered an address before the Architectural Guild of that city, last week, on "Interior Wiring."

Legal Notes.

SUING UNDER THE HENRY RAILWAY PATENTS.

A BILL of complaint has been entered in the United States Court for the Northern District of New York seeking to enjoin the operation of the Troy and Lansingburg Electric Road and recover damages from that company and its officers for infringement of patents 345,845 and 424,298 granted to John C. Henry. The patents in controversy cover the entire trolley system exclusive of motors and dynamos. Knight Brothers, of Temple Court, this city, are solicitors for the plaintiff.

In patent 424,298, claim 1 refers to the span wire construction where the trolley wires are supported over the street by insulators and span wires to poles at the sides of the street. Claims 6 and 8 cover the overhead trolley wires supported by suspension from transverse guy wires and a trolley held by spring pressure against the sides and bottom of the trolley wire.

In patent 345,845 claim 4 refers to the electrical distribution wherein separate wires are used over each track, they being coupled together electrically and supplied from the same source. Claim 5 covers the combination of insulated feed wires connected at intervals to the suspended trolley wires. Claim 10 covers all forms of insulators having openings or passageways for the trolley through them. Claims 14 and 15 relate to the curve construction where the trolley wires are arranged to describe the curve of the track and are held there by guy wires from their top or side to poles at the side of street.

"THE GENERAL ELECTRIC CO."

THE above name appears to have been selected for the Edison-Thomson-Houston consolidation, as intimated some weeks ago in THE ELECTRICAL ENGINEER; and a bill has been introduced in the New York Legislature incorporating the new company, with special privileges and powers. If a liberal charter is not granted, the company will go to New Jersey for incorporation.

Letters to the Editor.

THE WESTON VOLTMETER.

THE remarks of Mr. Evershed, quoted by you on page 291 of THE ELECTRICAL ENGINEER of March 16, in reference to Mr. Weston's instruments, ought not to pass without comment. He says that "they are only d'Arsonval galvanometers, in which the current is led in by the phosphor bronze hair-springs which also act as the controlling force." The feature of a skeleton coil traversed by the current, delicately suspended in a strong permanent magnetic field, is common, it is true, not only to the Weston and d'Arsonval galvanometers, but to the syphon recorder of Thomson as well. But the d'Arsonval galvanometer, like the Thomson mirror, strictly speaking, is adapted only to measurements by zero methods, its deflections not being proportional to the values of the current except through a very limited range. I conceive that the merit of Mr. Weston's apparatus, consists, among other things, in so modifying the relation of the field to the moving coil, that the action is proportional through a large range, thus adapting the principle of Thomson's coil to the requirements of an accurate direct-reading instrument.

FRANKLIN L. POPE.

MARCH 18, 1892.

WHAT AN ELECTRICAL ENGINEER SHOULD BE.

IN THE ELECTRICAL ENGINEER of February 18, Prof. Francis B. Crocker briefly discusses the question as to whether an electrical engineer should be chiefly mechanical or chiefly electrical; and his opinion is that the electrical engineer must be an electrical specialist and that mechanical engineering, though a necessary part of his preparation, is nevertheless merely incidental.

I do not hesitate to say that there are a good many electrical engineers who will take exceptions to this view. I have a wide acquaintance with electrical engineers in this country, and this acquaintance teaches me that the most successful electrical engineers are those who are the best equipped in mechanical engineering. As I look at it there is a wide difference between the electrician and the electrical engineer. The former is the man who is interested in experimental work, in the advance of the science of electricity, in the design of apparatus, etc., while the latter is the man who is interested in the operation of apparatus, in its installation, in its practical, commercial use or development. A man may be a perfectly good electrical engineer, one who could handle great equipments successfully, and yet may fail as an electrician utterly. I could easily mention cases. And on the other hand, a man may be a brilliant electrician, one whose laboratory work excites admiration, and yet be a complete failure in what an electrical engineer would call "field work."

Prof. Crocker rather discussed what electrical engineers *are*, I think, than what they *should be*. Although I do not go so far as to say that an electrical engineer should be "nine-tenths mechanical and one-tenth electrical," yet most electrical engineers will, I think, agree that this view is nearer true than the opposite one. Perhaps it might be still nearer true to say that he should be ten-tenths electrical and ten-tenths mechanical.

With regard to *electricians* the case is different, though here also, I believe, a man must be largely mechanical to be successful. I heard Prof. Elihu Thomson say once, when speaking of a good draughtsman, who was an unsuccessful electrical apparatus designer, that the man "did not seem to see the current going through those secondaries." Unquestionably, a man should be more an electrical than mechanical to be a successful electrician. But if any one will search through the laboratories and electrical factories of the country he will find that the most successful electricians are the men who have had a thorough mechanical training. And in my opinion, the one great reason why the Crocker-Wheeler motor, for instance, has taken its present high position in the market, is because its mechanical details have been worked out with such care and ability.

OTIS K. STUART.

PHILADELPHIA.

TRANSMISSION AT ONE MILLION VOLTS.

IN you issue of March 9, under the heading, "Transmission at One Million Volts," appears an article which sounds absurdly funny. The writer informs us that it is customary in central arc lighting stations to connect constant current machines in series· Now since this practice is followed to a *limited extent*, Mr. Dorman proposes, and sees no obstacle in the way of carrying it to an *unlimited extent*.

I have had considerable experience with constant current machines, and have always found, that a machine had to be *very* carefully insulated to stand a strain of from 3,000 to 4,000 volts.

Now Mr. Dorman has carefully informed us how to insulate the conductors on the line for a pressure of 1,000,000 volts or even, as he says, 2,000,000 or 3,000,000 volts (the feasibility of which I question). But after stating his intention of describing his generating machinery, he simply says that he uses constant current machines, neglecting to tell us anything about the insulation of dynamo or motor.

Surely this is a question of vital importance, and I would be very glad if Mr. Dorman would give us a little more information in detail of a dynamo which would stand the voltage of which he speaks.

CHAS. N. PEAKE.

LYNN, MASS.

A NEW FORMULA.

IN view of the Thomson-Houston-Edison consolidation, and in view of the proposed consolidation of the Edison Association with the National Electric Light Association, it has occurred to me that the latter should have a new badge, to replace the old one of $C = \frac{E}{R}$ by the following, $E = \frac{T}{H}$.

W. T.

Society and Club Notes.

NEW YORK ELECTRIC CLUB.

THE following important circular has been sent to all the active and associate members of the New York Electric club. It is to be hoped and expected that the members will respond promptly and unanimously to this appeal. We happen to know that the past and present management of the club, with a few of its friends, have done all that is possible to meet the contingency when it has arisen in critical shape, but no board can be exected to assume and meet such burdens indefinitely. It is a question for the membership and for the membership alone.

> The Board of Managers have for some time past had under consideration the finances of the club. They have found that the income is insufficient to meet current liabilities. The club has been running behind upwards of $3,000 per year; which is mainly due to the expense of running the café, and to lack of support by the members.
>
> In order to bring the expenses within the income of the club, the Board of Managers, at a recent meeting, decided to close the café temporarily, and to run the bar, billiard-room and sleeping-rooms of the club on a strictly cash basis. The expense of running the club under these conditions will, it is believed, be within the income. It now remains to provide for the indebtedness previously incurred, amounting to $8,000 exclusive of the bonded debt.
>
> To provide for the current debt the Board of Managers, at its meeting, March 17, passed a resolution to assess the members of the club as follows:

Active members	$30 each.
Associate members	15 "

To meet the present demand it will be necessary that a check from each member be received by the Treasurer not later than Thursday, March 31, 1892, and it is hoped that every member, active and associate, will recognize the importance of prompt attention to this request; inasmuch as the continuance of the club and the retention of its club house depend upon the prompt collection of this assessment.

If the requisite response be given to this assessment it is believed that the club has before it a prosperous future.

By order of the Board of Managers.

SAMUEL INSULL,
President.
GEO. M. PHELPS,
Treasurer.
STEPHEN L. COLES,
Secretary.

NEW YORK ELECTRICAL SOCIETY.

THE next regular meeting of this society will be held in Prof. Chandler's lecture-room at Columbia College on Friday, March 25, at 8 p. m. Prof. F. B. Crocker will deliver a lecture on "Electrical Measuring Instruments," in which he will demonstrate the principles of construction of the most important instruments for the measurement of continuous and alternating currents, and will illustrate their use in actual practice by the aid of the large collection of instruments belonging to Columbia College.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the meeting of Council, held March 15, the following gentlemen were elected to associate membership:

Aldrich, William S., associate in mechanical engineering in the department of electrical engineering, Johns Hopkins University, Baltimore, Md.

Blakeney, W. H., firm of Blakeney & Reume, mechanical and electrical engineers, 33 Bath street, Glasgow, Scotland.

Carroll, Dwight F., instructor in electrical engineering, Lehigh University, South Bethlehem, Pa.

Lenz, Charles Otto, draughtsman (electrical), Edison General Electric Co., box 3,067, New York City.

Martin, A. J., general superintendent, West End Electric Company, 1310 N. 29th street, Philadelphia, Pa.

Perot, L. Knowles, consulting electrical engineer, 308 Walnut street, Philadelphia, Pa.

Sachs, Joseph, electrician, the American Engineering Company, 109 World Building; residence, 1839 Lexington avenue, New York City.

Wessels, Edward J., New York agent, the Short Electric Railway Company, 121 World Building, New York City.

The annual meeting for the election of officers, the reception of yearly reports and the transaction of business will be held at the headquarters of the Institute; in New York City, on Tuesday, May 17, followed by a dinner in the evening.

The general meeting for the reading and discussion of professional papers will be held at Chicago on Monday and Tuesday, the 6th and 7th of June. The programme of papers is now in preparation, and full particulars will be given out as soon as possible.

POLYTECHNIC SECTION, AMERICAN INSTITUTE—MR. SCHIEREN ON LEATHER BELTING.

AT the meeting of the Polytechnic Section of the American Institute of New York, on Thursday evening, March 17, Mr. Chas. A. Schieren read a paper on the "Art of Tanning Leather and Making Belting." He showed in the lecture the various processes through which a hide passes in the tannery, which were all beautifully illustrated by lantern slides. The various departments through which the hide passes in the tannery, the machinery used for manipulating the leather, as well as the grinding and leaching of the bark, were illustrated and thrown on a large canvas by lantern slides. This made the lecture doubly interesting because the audience could get a clearer idea of the manipulation of leather in the tannery.

In the making of belting Mr. Schieren showed a hide of leather from which were taken four pieces of equal length and width; they had been submitted to a test by a powerful testing machine of the Fairbanks Scale Co., of New York. These pieces were all eighteen inches long, and two inches wide, and were numbered. Number three, being cut from the lower part of the centre, broke at 2,490 pounds strain, which would give the piece a transverse strength of 14,940 pounds per square foot. Number four, cut from the upper part of the centre of the hide, broke at 2,000 pounds. Number five, cut from the lower part of a shoulder piece, broke at 1,390 pounds. Number six, cut from the upper part of a shoulder, broke at 1,130 pounds.

The lecturer explained that very many belts were sold and offered in the market which were made from one piece of centre on one side, and a piece of shoulder on the other side. He clearly proved that such belts were defective because of the shoulder being so much more liable to stretch, and not being able to withstand the strain of a centre piece by at least forty-three per cent. it would be a serious mistake to put the two pieces together for transmission of power, on account of the unequal tension. A belt would be superior if two shoulders were used, or two centre pieces, separately. He claimed that a belt made from two centres could withstand a transverse strain of nearly 26,940 pounds to the square foot, whereas, a belt made from shoulders would hardly stand 15,120 pounds strain, and such belts would not be reliable, especially on dynamos, or swift running machinery, in fact, for almost any drive where a belt is subjected to severe train.

PROF. A. G. BELL AND THE ELECTRICAL ENGINEERS.

As president of the American Institute of Electrical Engineers, Prof. Alex. Graham Bell has promised to deliver a lecture before that body some time in April—probably the 19th. It is understood that his subject will be "Radiophony," a theme full of interest, and one that, as far as we are aware, has never been brought before a New York audience. It is expected that the lecture will be delivered at Columbia College, and that, as usual, on these special occasions, ladies will be present. In view of the large attendance at these gatherings, admission will be by card. Due announcement as to details will be given later on.

CHICAGO ELECTRIC CLUB.

THE CHICAGO ELECTRIC CLUB have arranged for a series of papers on subjects connected with the electric railway, as follows:

March 21. One Motor for Car Equipment.
Two Motors for Car Equipment.
March 28. The Gearless Motor.
The Single Reduction Motor.
April 4. Debate, "Resolved, We Should Have the Trolley System in Chicago."

OHIO GAS-LIGHT ASSOCIATION.

THE OHIO GAS-LIGHT ASSOCIATION, 150 members present, have endorsed the action of Eastern gas associations in resolving to use their influence to prevent the five-million-dollar Government loan to the World's Fair unless the World's Fair Commission deals more fairly with the gas people.

They claim that the commission has set apart a million and a half dollars to make an electric light display and not a dollar for a gas-light exhibit. Worse than this, the location of the Gas-Light Building, built at private expense, is in an out-of-the-way place.

SOUTHEASTERN TARIFF ASSOCIATION.

AT the meeting last week of the S. E. T. A. in Washington, the following resolutions relating to electrical work were adopted:

Resolved: That the basis rates of electric light and power houses in first-class cities be 1 per cent., and in other cities remain as they are.

Resolved: That the Executive Committee shall insist on perfect insulation of electric wires, and that an extra charge be made where wires are not in conduits.

Resolved: That the Executive Committee co-operate with the Atlanta Fire Department in its present system of inspecting buildings, and if necessary, appoint an electrical expert whose salary shall not exceed $100 a month.

Obituary.

C. J. VAN DEPOELE.

CHARLES J. VAN DEPOELE, one of the first to adapt electricity to the work of mining and electric railroading, died on March 18, at Lynn, Mass. He was forty-six years old.

Mr. Van Depoele was born in Belgium, and at an early age displayed great interest in machinery and in electrical matters, but his parents discouraged his investigations in this line and apprenticed him to the cabinet-making trade. Going to Detroit in 1869, he began the manufacture of art furniture, and from that time on for several years he spent all of his leisure and much of his revenue from the furniture business in electrical experiments. In 1877 he built an electrical laboratory, and there constructed several large dynamos, with which exhibitions were given. In 1878 he lit up Forepaugh's circus, and after that Recreation Park was illuminated nightly for the benefit of the baseball enthusiasts. A great hobby of his was the propulsion of cars by electricity, in which his first experiments were made in 1882. His first commercial road was equipped in 1885 at South Bend, Ind. He had also a great interest in telpherage. In the spring of 1888 the Van Depoele Company sold out to the Thomson-Houston Electric Company of Boston, whose service Mr. Van Depoele thereupon entered as electrician of the railway department. A fine portrait of Mr. Van Depoele and full biographical sketch of him will be found in THE ELECTRICAL ENGINEER of June 25, 1890.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The feeling of readers toward a paper determines the action of the advertisers in it.

QUEEN & CO.

It is not often that electrical companies announce "bargain days" or "annual spring sales" but an interesting circular just received would indicate that Queen & Co. have decided that old stock is worse than none, and the way they have cut the prices of some ammeters and voltmeters is something heretofore unknown in the instrument business. This startling reduction of course does not apply to any of their regular stock, but they happen to have on hand a good many Ayrton & Perry spring ammeters and voltmeters which do not find so ready a sale now as formerly, for obvious reasons explained in the circular from which we quote:

"When these ammeters and voltmeters were first placed on the market some five years ago, they were without doubt the best instruments made for both experimental and practical measurements. Their points of excellence were and still are portability, absence of permanent magnets; constancy; and direct reading proportional scales. As a consequence we have supplied them to most of the large manufacturing companies, to many central stations, and to the principal college laboratories. Recently we have engaged extensively in the manufacture of ammeters and voltmeters for all purposes, and find that for exact work we can produce instruments of greater accuracy, and for station use of equal accuracy at a less cost than the Ayrton and Perry type.

"We have decided, in consequence, to insure a prompt disposal of the instruments of this make still on our shelves, and have reduced their prices *fifty per cent.* from last year. This reduction is made without regard to cost, and it is a rare opportunity to obtain a good ammeter or voltmeter for experimental or every-day use, at a marvelously low figure."

Everybody is familiar with this type of instrument and those wishing to take advantage of an exceptional opportunity should send to Queen & Co. for a copy of circular No. 275.

THOMSON-HOUSTON ELECTRIC ELEVATORS.

Although the use of electricity as a motive power for freight and passenger elevators is of comparatively recent date, the Thomson-Houston Motor Company has devoted much time and thought to the perfection of apparatus for this purpose.

The first cost of an electric elevator installation is very much in its favor, as the electric motor takes the place of the steam plant. The cost of current for the motor is no more than the cost of coal for the steam plant, and with the use of the electric current come none of the disagreeable features—heat, dust, ashes, etc.—which are necessary attendants upon the use of coal. With the hydraulic elevator as much water is required to lift one person as for a full load, while with the electric elevator the power used is in direct proportion to the weight being raised.

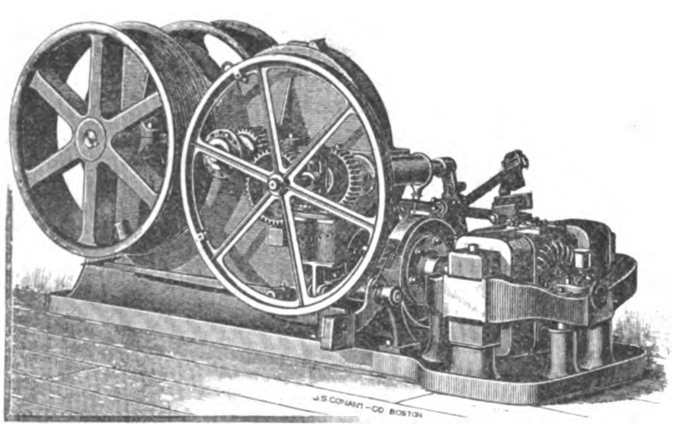


Fig. 1.—Thomson-Houston Reversible Elevator Motor.

The Thomson-Houston apparatus can be easily applied to steam and hydraulic elevators already installed. Where elevators are operated by counter-shaft and belt machines, such as are in general use for freight work, a reversible elevator motor is attached by gears directly to the machines, as shown in Fig. 1, and the electric switch and rheostat connected to present hand-operating cables, the motor starting, stopping and reversing simultaneously with the car, thus using power only when the car is in motion, and then using only sufficient power to lift the actual load in the car.

For a steam pump operating an hydraulic elevator an electric pump of like capacity is substituted, which runs only when pressure is lowered by the upward movement of the car, and is automatically stopped when pressure reaches the maximum. Instead of operating by city pressure, an electric pump can be installed to force the water directly into the hydraulic cylinder, or for supplying a pressure or roof tank, from which the elevator is operated.

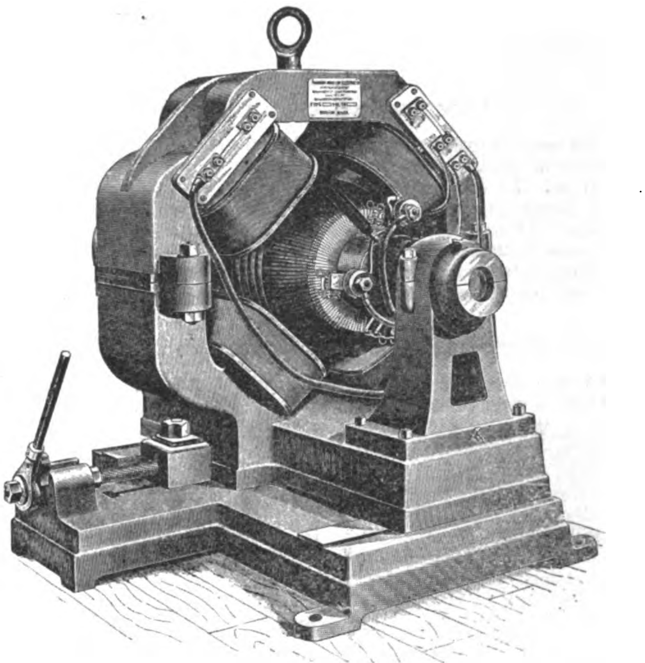

Fig. 2.—Thomson-Houston Multipolar Elevator Motor.

The illustration, Fig. 2, shows the type of large Thomson-Houston motor, especially adapted to elevator work. It is of the multipolar type, having four poles and a Gramme ring armature. This construction renders possible a very slow speed and a very large output for the size of the machine. The one shown is of 110 h. p., and runs at a speed of only 700 revolutions. The commutator has a large number of segments, and the current is collected by four sets of carbon brushes which bear radially upon the commutator. The machine is equipped with self-oiling bearings, and in general design is the same as the Thomson-Houston multipolar generator, which is now being so extensively used and which is giving such general satisfaction in railway power stations.

THE TORONTO AND MIMICO ELECTRIC RAILWAY.

The Reliance Electric Manufacturing Company, of Waterford, Ont., who are building the Rae system in Canada have secured the contract for the equipment of the Toronto and Mimico Electric Railway. This road will start from the terminus of the Toronto City Railway Company's lines on Queen street and extend to the village of Mimico and eventually to Long Branch, a total distance of about seven miles. The road runs along the lake shore the entire distance. The Reliance Company have the contract for the entire equipment exclusive of track. The power station will contain one Armington & Sims engine of the compound condensing type, 125 h. p., and the Rae station electrical apparatus consisting of one 85 K. W. generator and necessary appliances. The motors for this road are of Mr. Rae's latest design of single reduction motors, which are at present only built in Canada.

THE CLARK ELECTRIC CO.

The above company, of 192 Broadway, New York, have published a very interesting and artistic pamphlet on their system of arc lighting, which they characterize as "the cheapest illumination in the world." It is well illustrated with their apparatus, and details are given as to each feature. Several of the medals won by the system are shown, printed in bronze inks. Special reference is made to the Clark search light and Clark projection arc light, both excellent pieces of mechanism. Of the latter we can speak in very strong praise, its use at the headquarters of the Mechanical and Electrical Engineers having been most satisfactory.

THE "KNOWLES" ARC LAMP FOR ALL CIRCUITS.

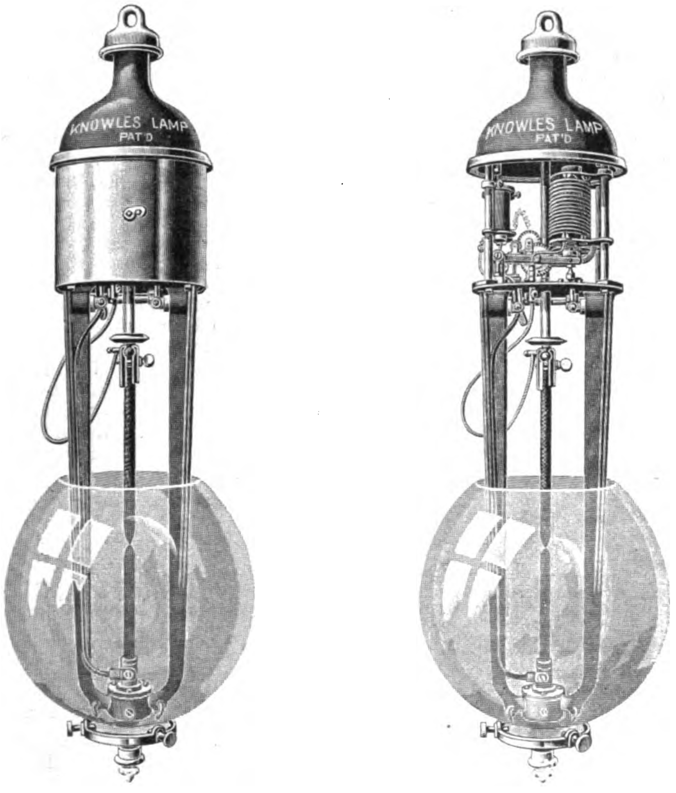
A PRACTICALLY perfect system of electric lighting should be of such a character that any desired kind of lamp, either arc or incandescent can be run from a single system of wiring, thus obviating the necessity and expense of providing a separate system of conductors for each kind of lamp. At the present time by far the largest portion of all electric lighting is by means of the incandescent lamp, and but few of the many installations of this character use any kind of light other than the incandescent. In a great many instances the best and most satisfactory lighting would be obtained by the use of a much more powerful light, such as the arc lamp.

A practically perfect arc lamp for use on incandescent circuits should embody the following essential features; it should be neat in appearance, compact and of light weight; dust and weather proof; well ventilated; simple and accurate in construction; perfect in regulation; noiseless in running; non-differential in action (no pumping) and be perfectly insulated. It should also be capable of burning for at least ten hours with a single pair of carbons and without retrimming and it should be low in cost.

The "Knowles" lamp is intended to fill all these requirements as nearly as it is possible to do so. The lamp is practically a universal lamp working equally well upon a constant current or constant potential circuit or alternating current circuit. It runs at any voltage and any current and is a radical departure in its construction from all existing types of arc lamps.

Its general construction may be seen in the accompanying illustrations, Fig. 1, showing the lamp complete and ready for use and Fig. 2 showing the lamp with the case removed so that the working mechanism may be seen.

Its length is 40 inches over all and its weight, 20 pounds. It is neat in appearance and compact in construction. There is no projecting horn on the top of the lamp and no projecting globe-holding tube on the bottom and no unsightly projecting binding posts. It is so designed that it may be hung close up to the ceiling of a room and its length is such, that, even in a low-studded room, it will be clear of the heads of persons passing beneath it, thus obviating the necessity for making holes in the ceiling so that it can be hung high enough up to be out of the way. Its feed movement is very simple and accurate in construction and operation and not liable to get out of order. The lamp case is dust and weather poof and can easily be removed while the lamp is in operation, and the lamp is ventilated in such a manner that any heat generated in the magnet coils is rapidly carried away and dissipated. The dust and weather proof character of the lamp enables it to be used out of doors without the necessity of its being covered by a protecting hood or canopy. There are only two pieces of insulation in the lamp and these are of a material which is non-combustible and not affected by moisture.



FIGS. 1 AND 2.—THE "KNOWLES" ARC LAMP.

The lamp is non-differential in its character, its feed being positive in its action, and free from all pumping or jiggling. The lamp operates normally at about 50 volts pressure and at a current of from 6½ to 7 amperes. It will run two in series on a 110-volt circuit, or as many in series of any circuit as the circuit pressure is a multiple of 50 volts. The lamp will run on any desired current from 5 to 10 amperes and when once adjusted needs no alteration of adjustment for any variation of current between these limits.

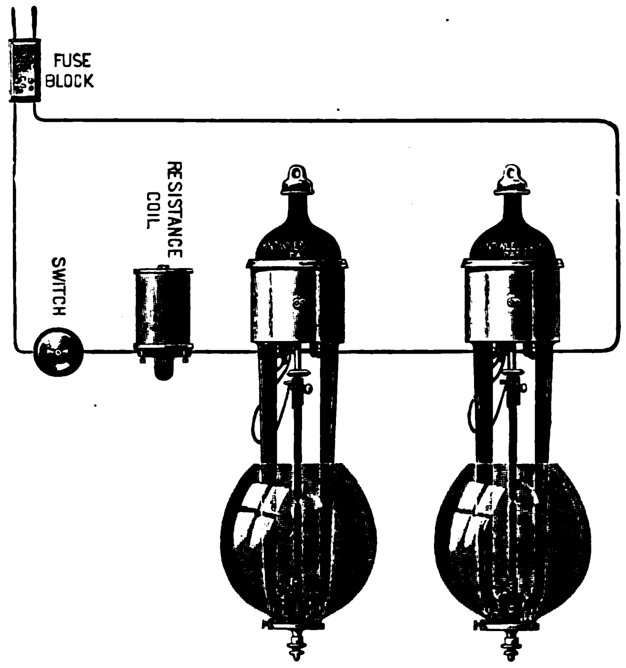


FIG. 3.—THE "KNOWLES" ARC LAMP.

The lamp when trimmed with a proper size and kind of carbon will burn at a current of from 6½ to 7 amperes and at 50 volts pressure for about 12 hours thus making it a practical all-night single-carbon lamp. The lamp is noiseless in running, and gives a pure white steady light with no flickering, hissing or sputtering, resembling closely in appearance a very large incandescent lamp.

Fig. 3 shows the manner of connecting and arranging the lamps when two are run in series upon a 110-volt circuit, the diagram is the same for other combinations of lamps, as, for example, when four run in series upon a 220-volt circuit or 10 in series upon a 500-volt circuit merely substituting the required number of lamps for the two shown.

The lamp is provided with a ceiling hanger-board when used indoors and with a substitute resistance equal to that of the lamp when more than two are run in series upon a constant potential circuit and with an automatic cut-out when run in series upon a constant current circuit.

This lamp was invented and patented by Edward R. Knowles, chief electrician of the Schuyler Electric Company, of Middletown, and has been adopted by the Thomson-Houston Electric Company, for all their offices.

E. W. WILSON & CO.

MESSRS. E. W. WILSON & Co. have just opened offices at No. 96 Broadway, where they propose to carry on a general banking business, including the purchase and sale of all securities dealt in on the New York Stock Exchange. The members of the firm are Mr. Edward W. Wilson and Mr. Archd. A. Watson. Mr. Wilson has been actively engaged in the electrical line, handling the securities of electric lighting and kindred companies, especially those associated with Thomson-Houston interests. Mr. Watson was formerly for five years of the firm of Watson Bros., now dissolved. He is a member of the New York Stock Exchange and represents the interests of the house on the floor of that institution. They will make a special feature of the handling of investment securities and the purchase and sale of the controlling interest of the stocks of electric lighting and street railroad companies' property. Mr. Wilson has already scored some considerable successes in this field.

ANNUAL MEETING OF THE BRUSH ELECTRIC CO.

THE annual meeting of the Brush Electric Company was held at the office of the company on March 15. The following directors for the ensuing year were elected: S. A. Barton, Boston; J. S. Bartlett, Boston; Myron T. Herrick, Cleveland; J. Potter, Cleveland; C. A. Coffin, Boston; William B. Bolton, Cleveland; S. M. Hamill, Cleveland.

Immediately after the stockholders' meeting the new board of directors met and elected the following officers: S. A. Barton, president, Boston; John S. Bartlett, first vice-president, Boston; C. A. Coffin, second vice-president, Boston; S. M. Hamill, secretary; L. B. Le Vake, assistant secretary; J. Potter, treasurer; A. H. Hough, assistant treasurer; William B. Bolton, general counsel; J. B. Hughes, auditor; S. H. Short, general electrician; F. A. Scheffler, superintendent; C. W. Phipps, assistant superintendent; S. M. Hamill, general manager—all of Cleveland.

Advisory Committee—J. Potter, William B. Bolton, S. M. Hamill.

Manufacturing Committee—S. H. Short, F. A. Scheffler, S. M. Hamill.

THE HOTEL BRIGHTON ISOLATED PLANT AT ATLANTIC CITY.

MR. FREDERICK HEMSLEY, the owner of the Hotel Brighton, has just completed extensive alterations and additions to this well-known house. As it has not been closed for over seven years this was the first opportunity that offered for the introduction of the electric light.

After obtaining a number of proposals from the electric light companies for the equipment the owner decided to place the matter in the hands of a consulting engineer, and Dr. W. A. Drysdale, of Philadelphia, was selected and instructed to have the entire installation completed in time for the opening, a period of 30 days. The time allowed was extremely limited, as specifications, plans, drawings, estimates and contracts, as well as the actual construction, had to be completed within this time.

The hotel building was wired for 650 lights, in addition to some 50 lights distributed in the help's quarters, engine-room, etc., making in all some 700 lights. The highest class of construction was insisted upon throughout the entire installation; the majority of these lights were placed in rooms requiring one or two lamps, and all material had to be obtained outside of Atlantic City. There was very little delay in the prosecution of the work, owing to the complete arrangements made, and on the afternoon of the thirtieth day the entire installation, including steam plant and dynamos, was ready for operation and after satisfactory tests had been made was accepted for the owner by the consulting engineer.

Much credit is due the contractors for the thoroughness of the work and the manner in which the spirit of the instructions of the consulting engineer were carried out.

The United States Electric Lighting Co. were awarded the contract for the dynamos, wiring and electrical equipment, the Stearns Manufacturing Company, of Erie, for the engines, the Horn, Brannen & Forsyth Manufacturing Company, of Philadelphia, for the fixtures, and Mr. John F. Trachsel, of Philadelphia, for the piping.

WASHINGTON, PA., ELECTRIC LIGHT AND POWER CO.

WASHINGTON, PA., has been the scene of an electrical development worthy of a town twice its size. The plant of the Washington Electric Light and Power Co. is now installed in a fine brick building 110 by 37 feet. It comprises one Fort Wayne alternating dynamo of 1,300 lights; one Westinghouse alternating dynamo of 750 lights, one of 500 lights, and a Westinghouse arc machine of 60 lights. There are also two United States generators of 80 h. p. The steam plant consists of one Ball engine of 60 h. p., one Taylor of 100 h. p., and three Westinghouse compound of 100 h. p. each. Steam is furnished from three boilers of 360 h. p. total capacity, and one boiler of 60 h. p. not in use at present.

The current for the Washington Electric Railway is supplied from this plant. The road has at present five cars with two motors of 20 h. p. each. Three miles of track are in use. Both companies are doing a good business, and find the demand increasing all the time. Mr. T. R. Branner, electrician, of Washington, Pa., installed the whole plant, which is working admirably and is a credit to a live and progressive community.

EDISON CENTRAL STATION LIGHTING.

A MOST interesting and very tasteful pamphlet has been issued on "Central Station Lighting" by the Edison General Electric Company. It embraces arc as well as incandescent work, but is specially devoted to the latter, regarding which, and the three-wire system it gives a variety of most useful information. There are many fine cuts to illustrate the text. One important part of the pamphlet deals with the legal status of the lamp suits. The pamphlet is supplemented by a number of illustrations of Edison central stations, exterior and interior, and by a set of tables, units, etc. The pamphlet bears the imprint of Bartlett & Co., a fact that speaks for the high artistic quality of the work.

THE C. & C. MOTOR IN THE WEST.

THE "C. & C." ELECTRIC MOTOR COMPANY have established a branch at Chicago, where they will occupy the large ground floor store at 201 Madison street, that city. The facilities for the convenience of their customers noticed in the New York house will be found duplicated in the Chicago establishment, where the company will carry in stock all sizes of the "C. & C." motors and dynamos; also parts of same for replacing worn or broken machines Users of electric power located in the West are cordially invited to call. The intention in establishing this branch office is to extend the same privileges to purchasers in Chicago, both as respects prices and delivery of machines, that would be obtained by direct application at the company's factory in New York.

Owing to an increasing demand for their motors from that section, the "C. & C." Electric Motor Company have opened a branch establishment in Portland, Oregon. They are admirably located at 53 and 55 North Front street, where they will carry in stock all sizes and all parts of the "C. & C." motors and dynamos. Parties located in that territory having business with the company will find the Portland branch a great convenience.

NEW QUARTERS FOR THE POSTAL TELEGRAPH CO.

THE POSTAL TELEGRAPH CO. has leased property 70 by 100 at the corner of Murray street and Broadway from the Trinity Church estate, and will put up there a fine large office building. It will occupy part itself, and expects to have the best telegraphic headquarters in the country, Work will begin on the new building this summer.

A PROPOSED THIRTY-ONE MILE ELECTRIC ROAD.

MR. E. R. HOTSENPILLER, proprietor of the Park Hotel, Magnetic Bath House and grounds etc., at Magnetic Springs, O., writes us that he has formed a project for an electric railway from Columbus, O., to Magnetic Springs, a distance of thirty-one miles. Articles of incorporation are now being filed with the secretary of state, and it looks as though the road will be actively pushed.

PROF. ROWLAND'S "PERFECT SCREW."

THE *Baltimore American* recently published a description of what is known as a "perfect screw," made by Prof. Henry A. Rowland, of the Johns Hopkins University, for his wonderful dividing engines, with which he rules tens of thousands of lines to the inch, to make the "gratings" enabling scientists to study accurately the spectrum of the sun, etc. "This new and perfect screw," it says, "which has been the subject of so much experiment by the great scientist, and whose improvements are the result of the close study of certain unsatisfactory experiments, is of steel. The last one was of Bessemer steel, which it was thought, combined both the requisite softness and homogeneity. But for the new one, Jessop's tool steel, annealed at the factory, has been found to have the required fine grain and the softness, and to be far more perfectly homogeneous than those previously made. It was cut in the workshop of the physical laboratory of the Johns Hopkins, on an ordinary lathe, and thereafter ground with fine emery under water and oil maintained at a certain temperature for over three weeks." Following the above paragraph is a lengthy article about the machine, said to be capable of ruling 1,000,000 lines to the inch, and its uses for scientific purposes.

The attention of Messrs. William Jessop & Sons, of New York, was called to this voluntary compliment and they wrote to Mr. William G. Wetherall, of Baltimore, who for many years has kept the Jessop steel on sale in his warehouse, and asked if he had sold to the Johns Hopkins University the steel above mentioned. This inquiry brought the following reply:

BALTIMORE, December 29, 1891.

MESSRS. WM. JESSOP & SONS,
NEW YORK.

Dear Sirs:—

Your favor of the 28th inst. is to hand, and noted. We beg to say in reply that we sold the steel referred to in the newspaper article you enclosed (a bar 1⅛ R of your annealed steel, in August last, to the machinist who works for the Hopkins University.

We are so accustomed to having your steel turn out satisfactorily that it occasioned no remark, as only the contrary would have surprised us.

Wishing you the "Compliments of the Season," we remain,

Very truly yours,
W. G. WETHERALL."

The factory of Messrs. Jessop and Sons, Limited, is in Sheffield, England, and was established in 1793. The principal depot in the United States is at 91 John street, New York, where a full stock of all sizes of Jessop's best tool steel, annealed and unannealed, of superior quality, can always be found. Their depots and warehouses are also widely distributed throughout the world.

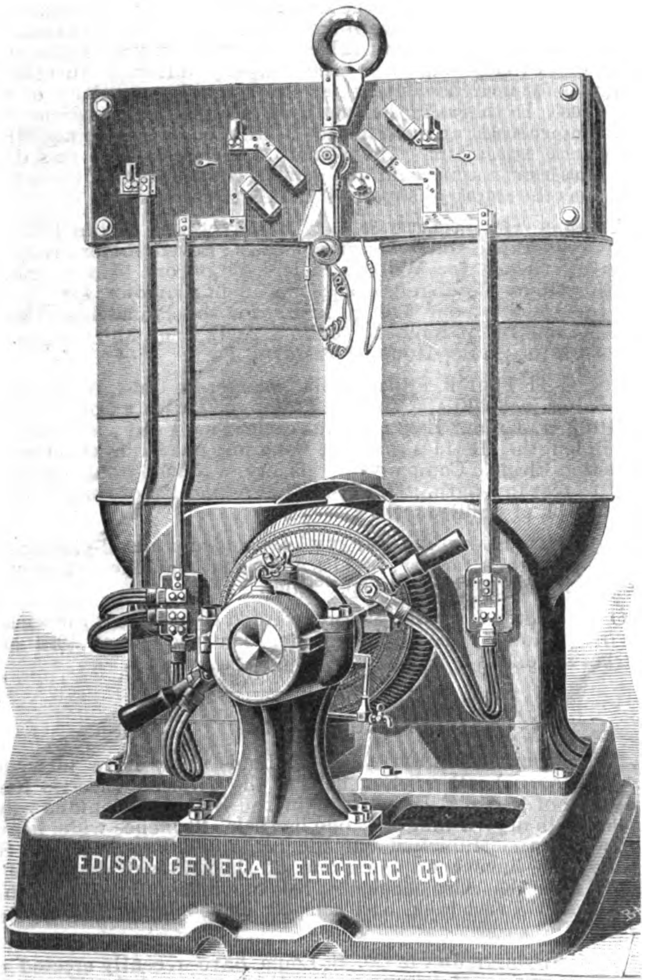
MESSRS. SUTTON & STEELE, of Dallas, have brought out a new dynamo for arc and incandescent lighting. It is said to be one of the smallest and cheapest on the market, for its output.

THE IMPROVED EDISON 200 K. W. GENERATOR.

The elimination of objectionable features from electric lighting and electric power apparatus, and the introduction of improvements is the present aim of all manufacturers of electrical devices. The accompanying illustration shows an Edison 200 kilowatt generator of the latest form illustrating this. It is of the bi-polar type, with the general features of which every practical electrician is acquainted.

The series field is built up of sections, wound on spools which are slipped over the cores and then properly connected up. Should a fault manifest itself, it can be located, and the spool in which it appears can be removed, repaired and replaced, or another substituted at once without-loss of time. Expenditure for repairs is thus reduced to a minimum.

To adapt this generator to the demands of electric railway service, the field has been provided with a compound winding, easily adjusted to meet the necessary requirements by means of a shunt coil, conveniently placed in the backboard of the keeper. The bearings being located close to the base frame, the centre of gravity of the armature is low and great stability is thus secured. Self-oiling bearings and carbon brushes contribute to diminish the necessary attention to a minimum.



EDISON GENERAL ELECTRIC CO.

The Improved Edison 200 K. W. Generator.

A considerable number of these high capacity generators have already been installed by the Edison General Electric Company throughout the country, and the advantages they offer have been duly appreciated.

MR. M. J. MARTINEZ.

This gentleman has recently associated himself with the Geo. F. Blake Manufacturing Co., of 95 and 97 Liberty street, this city, where he will take charge of the Central and South American export department. The company manufacture a large variety of pumping machinery for water-works, vacuum and boiler feed pumps, air and ammonia compressors, etc. Mr. Martinez's experience as a mechanical engineer together with his knowledge of the needs of export customers will make him a valuable acquisition to company.

NEW ENGLAND NOTES.

The Bradbury Stone Storage Battery Company, of Lowell, are making quite a success of their storage battery, and are in receipt of many of the warmest kind of testimonials regarding its work. The car which they equipped with their batteries in Sioux City, continues to give the best of satisfaction, and the street railway company are anxious to have another car equipped. They are at present making arrangements to increase their facilities for the manufacture of storage batteries, and are compiling a very interesting catalogue descriptive of the battery and containing a large number of testimonials from their customers. There is a good opportunity for an enterprising motor or car company to co-operate with the Bradbury Stone Company, in the line of pushing storage batteries for street car work.

The Electric Heat Alarm Company, of Boston, have just issued a neat little pamphlet descriptive of their system of protecting bearings from getting overheated. Their system, as already described in our columns, consists of a small cap containing mercury which is inserted in the cover of the bearings. Should the bearing get hot, the mercury expands and by making electrical contact with an alarm bell, which may be situated in any convenient place, at once warns the attendant engineer of the danger, when steps can at once be taken to prevent any damage. The pamphlet is well got up, and should be very interesting to all in charge of machinery of any kind.

The John Becker Manufacturing Company, of Fitchburg, Mass., have now got thoroughly installed in their new factory, into which they recently moved from Boston. The machinery is now all set up, and Mr. Becker reports that they have already shipped from Fitchburg several of their well-known milling machines. These machines are of special design with a very high rotary speed, and are well adapted for all kinds of electrical work. This company are also large founders of brass and bronze name plates and have a large trade with most of the electrical manufacturing companies.

The Mather Electric Company and the Perkins Electric Lamp Company have recently moved into their new and handsome offices on the top floor of 116 Bedford street, Boston, the building in which they have been located for the past two years. Their offices extend over the whole floor and are replete with every comfort and convenience to accommodate their largely increasing business. Among other features they have an excellent draughting-room, well lighted from a skylight in the top of the building, and will be able to attend to many inquiries and business matters that have hitherto been referred to Manchester.

The Holtzer-Cabot Electric Company, of Boston, have just issued a neat little pamphlet relating to the H. C. automatic motors, fan outfits, generators, plating machines and motor generators. This company have attained an enviable reputation on the quality of their varied manufactures, and in going into this heavier class of work, have adopted all that is best in motor practice, and have carefully calculated the mechanical and electrical designs, so that it is confidently expected that the H. C. motor will rapidly establish for itself a first-class reputation and will be able to compete with any on the market.

The Berlin Iron Bridge Company, of East Berlin, Conn., have taken the contract for a new boiler shop for the Dry Dock Engine Works, at Detroit, Mich. The building will be 63 feet in width by 201 feet in length and will be constructed by the Berlin Company. The building will be designed and built entirely throughout from the foundations by the Berlin Bridge Company. They not only furnish the iron work but supply the foundations, brick work, in fact, the whole building complete for the machinery.

The Thomson-Houston Electric Company have recently received the order for 360 railway motors of the W. P. 30 type for the Lynn and Boston Railway. This railway will have two stations of 5,000 horse power each, one in Lynn, near the coal wharves on Washington street and one in Chelsea near the ferry. Two M. P. 270 generators have been ordered at present, and it is expected the road will be in operation by midsummer, the work being pushed along as fast as circumstances will permit.

The Wainwright Manufacturing Company of Massachussetts, of Boston, have recently closed contracts for 16,000 horse power of their well-known heaters. These heaters are for the Lynn and Boston Electric Railway, the New York Electric Railway and the Albany Street Railway Company. This is the largest order that has ever been placed for feed-water heaters, and is a sufficient evidence of their sterling worth, and of their popularity amongst electrical engineers.

The Simplex Electrical Company, of Boston, have decided to discontinue their New York agency, hitherto held by Messrs. W. H. Gordon & Co. Until further arrangements are made Major Everts, assistant manager of the Simplex Company, will look after their interest in New York, with headquarters at the Imperial Hotel.

The Eastern Electric Supply and Construction Company, of Boston, have received the contract to build and equip complete the Worcester and Shrewsbury Electric Railway. There are at present three miles of track, which has hithertho been operated by a steam dummy, but it will soon be increased by other thirteen miles. They have also just equipped the factory of the Speare Manufacturing Company with a 200-light incandescent plant, using the Edison system.

The Eastern Electric Cable Company, of Boston, manufacturers of the famed Clark wire, have been forced to again increase their factory facilities, and have added another story to one of their buildings, which will be devoted to braiding purposes. Their business continues to increase steadily and they are now turning out fifty per cent. more wire than during the same period a year ago.

Mr. R. S. Brown, agent of the Westinghouse Electric and Manufacturing Company, has just closed a contract for six gearless motor equipments for the Waterville & Fairfield Railroad Company, Fairfield, Maine, and ten car equipments single reduction for the Boston Construction Company.

Mr. W. Roy Mitchell, as agent for the Edison General Electric Company, has closed contracts for electric light plants at Trinity College, Durham, N. C., Hygeia Plate Manufacturing Ice Co., Raleigh, N. C., and Salisbury Cotton Mills, Salisbury, N. C., during the past week.

The Perkins Electric Lamp Company, of 116 Bedford Street, Boston, have a neat little ivory paper cutter, which they will be glad to send to all costumers and friends.

WESTERN NOTES.

The Electric Appliance Company are exhibiting a very fine line of New England double-pole snap switches ranging from 10 to 100 amperes and with regular covers and flush caps. The flush cap switch is a recent improvement in snap switches and is intended for special work where it is desirable to have the switch set in the wall making the top of the switch flush with the surface. These are coming into use largely and the Electric Appliance Company has arranged to meet the demand by carrying them in both the New England double pole and the Acme 10 ampere single-pole switch.

Mr. W. A. Stiles, secretary and treasurer of the Van Depoele Electric Manufacturing Company, is secretary and one of the directors of the World's Fair Trust Fund Transportation Company, of 125 La Salle street, Chicago. The object of this company is to receive instalments and to issue certificates which will enable its patrons to visit the World's Fair cheaply and with the certainty of finding accommodation. The certificates are transferable and non-forfeitable, and a holder can also, if he wishes, have his money refunded at any time. The plan seems a very good one. It is a new form of the "Cook's Tourist" idea.

J. Lang & Co., 44 Michigan street, Chicago, Ill., have issued a neat catalogue of their patent steam and electrical specialties. The catalogue is arranged in the form of a folder, bound together by brass rivets. It is exceedingly handy and convenient to peruse. Their well-known main line, double-pole, throw-over and feeder switches are handsomely illustrated and concisely described. The fine line of switches for alternate currents which they manufacture are also shown up, with other various metal specialties for electrical and mechanical use.

Chas. G. Armstrong lectured before the Illinois Chapter of the American Institute of Architects, Monday evening, March 14, on the general subject of "Electricity in Architecture." In the course of his talk, which was illustrated by scores of experiments, he showed many points which, while coming properly within the sphere of the consulting electrician, ought still to be understood by the architects. The discussion of the lecture was no less attractive than the dinner preceding it, and showed how large a part the electrical fittings play in our large city buildings.

Mr. George Cutter has placed a very handsome framed lithograph picture of the Masonic Temple in his front office in a permanent state of brilliant illumination, with the legend upon it, that "Simplex conveys the juice." This is not only in the model, but in the original, through which some 65 miles of Simplex wander. This, according to Mr. Cutter, the electrical specialist of the West, is the insulation that never fails, and it produces a similar effect on the light.

Mr. H. W. Shurtz, electrical engineer of the Northwestern Electrical Engineering Co. of Portland, Oregon, passed through Chicago recently on his way East, where he was married on March 2 to Miss Josephine E. Leonard of Leonardville, N. J. Mr. and Mrs. Shurtz will return shortly to their far Western home in Oregon.

Mr. Frank H. Pond, pres't of the Pond Engineering Co. of St. Louis, was a Chicago visitor last week and received his usual hearty welcome.

The Pfister Hotel, at Milwaukee, is to have 3,000 incandescent lights, making one of the largest isolated plants in Wisconsin. The apparatus will be furnished by the Thomson-Houston Electric Co., while George Cutter is to supply the large batch of Simplex wire needed for this plant.

The Block Signal Plant which the Hall Signal Co. is to put in for the Chicago and Northwestern Railroad will require 227 miles of rubber-covered wires, and Simplex braided rubber has been selected for the purpose. This means another of Mr. Cutter's pet million-feet orders.

Mr. W. H. McKinlock, the well-known president of the Central Electric Co., is back from his recent trip to Florida, Cuba, etc., upon which he managed to combine considerable business with pleasure.

PHILADELPHIA NOTES.

The Duplex Electric Company, of Corry, Pa., have done themselves credit by installing a plant for the Erie City Iron Works, of Erie, Pa., which the *Erie Herald* says is "the largest arc light plant in Northwestern Pennsylvania. Two dynamos of forty arc lights capacity furnish electricity to sixty arc lights, that make night like joyous day. The company although furnishing dynamos for incandescent lights as well, makes a specialty of arc dynamos. In this as in the ones used to supply the incandescent lights, no rheostat or resistance coils are used, the machines being thoroughly automatic. The wiring of the giant shop was done in a superior manner, and the general construction of the whole plant has the stamp of superiority, akin to perfection."

Thomas H. Dallett & Co., manufacturers of the Billberg motors report the following recent sales: Seven motors ranging from 5 to 50 h. p. for William Sellers & Co.; one 10 h. p. motor for the Globe Cordage Works; one 10 h. p. motor for W. H. Snowden & Co.; one 6 h. p. motor for the Philadelphia Wire Works; one 1 h. p. motor for John & A. E. Lent, and one 5 h. p. motor for the Shuler House, Pottstown, Pa.

Mr. G. H. Fisher, Philadelphia manager for Chas. A. Schieren & Co., has just sold the Trenton Passenger Railway Company, of Trenton, N. J., four Electric belts, each 24 inches in width and 112 feet in length. Besides this they have just put in position for the Powelton Electric Company, of this city, a 36-inch double electric belt 132 feet in length. Mr. Fisher has a long list of smaller belts on his book of unfilled orders.

The Star Electrix Company have added a nickel-plating department to their factory, besides additional machines which will be used in turning out new specialties.

O. D. Pierce & Co. have been awarded the contract for wiring the new Hotel Venedig now under construction at 12th and Market streets.

ST. LOUIS NOTES.

The Shultz Belting Co. of St. Louis, Mo., have just sold two "Woven Leather" link belts to the Citizens' Electric Railway Co., of Decatur, Ill.; fifteen in the State of Montana; five in the State of Washington; one flat belt, 48 inches wide, heavy double, to the Municipal Electric Light and Power Co., of St. Louis, who have been using one of their 48-inch double belts for 19 months. Also one double belt to Clinton, Mass., 30 inches wide and 175 feet long, and one 36 inches wide and 210 feet long.

J. H. Siegrist, Jr., & Co., St Louis, have recently erected an "Ideal" engine of 150 h. p. in the factory of the Hamilton-Brown Shoe Co., St. Louis. This engine is used for running the dynamos of their large electric light plant.

NEW YORK NOTES.

Mr. J. W. Lattig, formerly supt. of telegraphs of the Lehigh Valley R. R. and more recently general supt. of the National Switch & Signal Co. of Easton, Pa., has accepted the position of general superintendent of the Electric Secret Service Company of New York, in special charge of their telegraph and signal department. We are told that this company has a surprise in store for the railroad and telegraph worlds.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

Electrical Engineer.

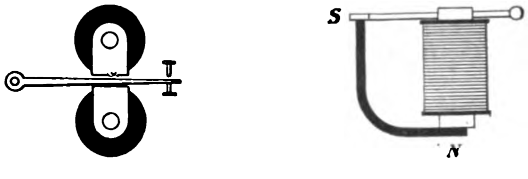
VOL. XIII. MARCH 30, 1892. No. 204.

MODERN AMERICAN TELEGRAPHIC APPARATUS.—I.

BY

F. W. Jones

IN glancing over the articles in the various books lately published on telegraphy descriptive of the systems and instruments used in the transmission of telegrams, it is hard for the reader to escape the impression that no improvements in this interesting and oldest department of electricity have been made for many years, and that both attention and invention have been attracted to the more ponderous application of electricity to railroads and stationary motors and lighting. It may be true that there is not the incentive for improvements in the telegraph field as in others, for the reason that it has been occupied by but two or three companies of any importance, and when once a piece of machinery is put in general use it requires a long time to induce the executive department to have it replaced by something different; but the writer hopes to be able to show that notwithstanding this great drawback, substantial improvements in telegraphic methods and apparatus have been made during recent years. For this purpose the principal types of apparatus will be taken up in order and the changes effected on the older types pointed out.



FIGS. 1 AND 2.—SIEMENS POLARIZED RELAY.

POLARIZED RELAYS.

The first polarized relay to be generally used in the United States was the well-known Siemens relay, illustrated in Figs. 1 and 2. Mr. G. M. Phelps, Sr., made a great improvement on this relay and secured a patent therefor in May, 1878. Instead of the main line electromagnets, E M, Fig. 3, resting directly on the permanent magnet, P, they were placed so that their poles were directly opposite the armature, and yoke extensions connected them to the permanent magnet. Their figure of merit was increased and their mechanical action improved. This relay I understand is being largely superseded in the Western Union Telegraph Company by the English Post Office pattern of relay. This is practically the same principle involved in the relay used in the Wheatstone automatic system as shown in Culley's "Hand-Book of Telegraphy" (edition of 1878, page 410, plate 2, Figs. 10 and 11), and described on page 404 (also shown on page 414, plate 3, full-size figures). This relay, Fig. 4, was adopted on account of its low inductance and time constant. As stated on page 411, "The extra current of demagnetization causes considerable diminution of speed. To lessen the extra current the quantity of iron in the cores of the electromagnet is made as small as possible and the cross-connecting bar (the yoke) is suppressed so as to form a pair of bar magnets instead of a horseshoe."

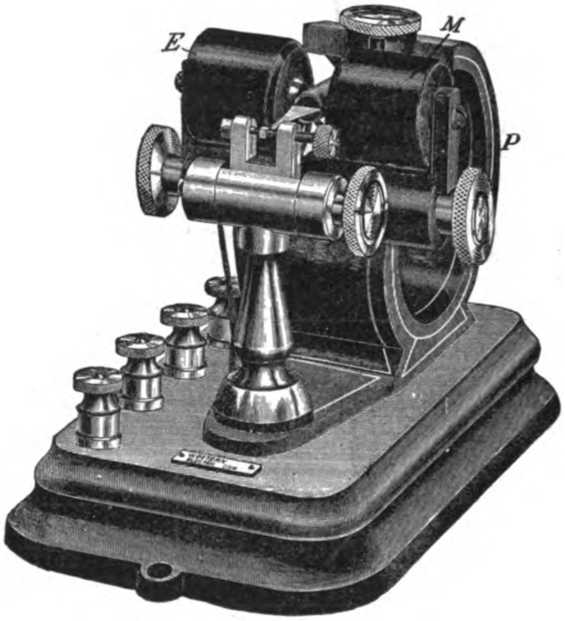


FIG. 3.—PHELPS POLARIZED RELAY.

A relay acting upon the same principle was designed by the writer as an improvement in 1884 and has had extensive use up to the present time for hand-signals, with very satisfactory results. It is shown in Figs. 5, 6 and 7. In this I have abolished the lugs or pole extensions and faced two electromagnets (each having a yoke) inwards, bringing their pole faces directly opposite the polarized soft-iron armatures. This is directly in accord with Mr. Frederick Higgins' suggestions in his paper printed in the *Journal of the Society of Telegraph Engineers*, 1877, page 122, in which he says: "Elongation of the poles beyond the bobbin and the attachment of pieces of iron to increase their surfaces exercise a retarding influence and are therefore avoided. * * * Flat armatures are used; numerous experiments having shown them to be best. Similar mag.

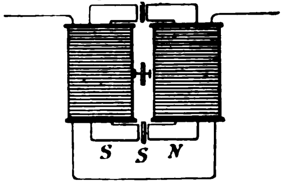

FIG. 4.—ENGLISH P. O. RELAY.

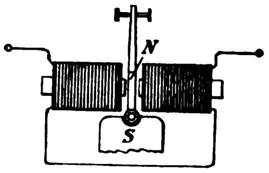

FIG. 5.—JONES POLARIZED RELAY.

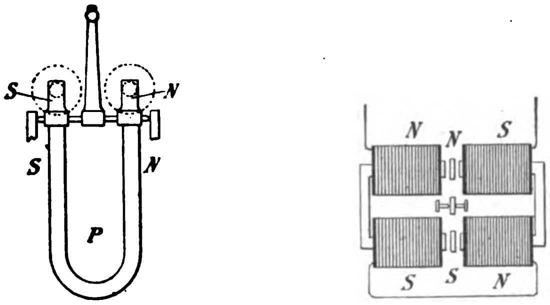
netic rays cannot easily be concentrated by convergence like those of heat or light; therefore lenticular or conical faces to the magnet poles or armatures are useless, or worse."

The improvement over the English form is more electrical than mechanical. The Western Union pattern, having aluminum tongues and moving parts accurately balanced and pivoted, very greatly offsets its higher time constant. It is expected, however, that the improved relay will receive similar attention to its mechanical action and show a higher figure of merit than at present.



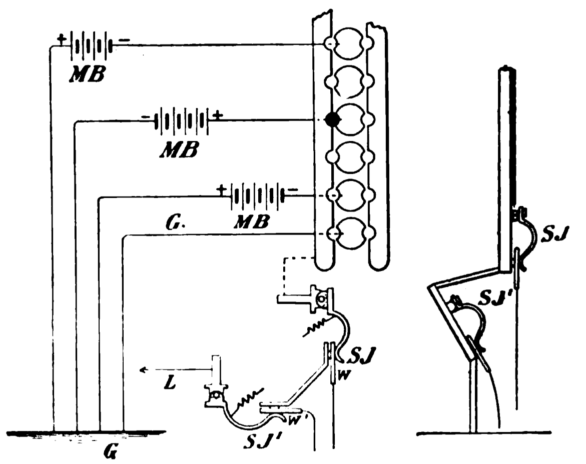
Figs. 6 and 7.—Jones Polarized Relay.

The accompanying table gives the comparative results obtained in a series of tests of the various types of instruments:

Name of relay polarized.	Resistance.	Inductance.	Time constant.	Figure of merit.	Current used.	
					Steady for inductance.	Reversals for figure merit.
	Ohms.	Henrys	Seconds.		Ampere.	Ampere.
Siemens, with lugs.	419	1.990	0.0048	700	0.0063	0.0014
Phelps, with lugs.	423	1.886	0.0045	400	0.0063	0.0025
English P. O. (W. U. style).	418	1.691	0.0041	625	0.0063	0.0016
Jones' Improved Relay.	418	1.310	0.0032	770	0.0063	0.0013

1. The inductance was measured with all the armatures, respectively, 4 mils from the poles, and the figure of merit with the armatures 32 mils distant, and the local contact point separated 8 mils.

It may be well for purposes of comparison to say that a common Morse relay of 148 ohms with its armature pressing against its poles has an inductance of 10.472 henrys and a time constant of .078 second with .0063 ampere current. With the armature 20 mils from the cores the inductance was 3.710 henrys.



S J, upper spring-jack. S J', lower spring-jack. G, earth.
M B, main batteries. L, line wire. W W' wedges and cords for instruments.

Figs. 8 and 9.—Old and New Switchboards.

SWITCHBOARDS.

Fig. 8 shows the old-style double spring-jack switchboard, which has demonstrated the superiority of the principles of its operation by a continuous use of many years. Upon this, also, there have been made very desirable changes by the Postal Telegraph Cable Company, as shown in Fig. 9.

The improvement consists in changing the position of the lower set of spring-jacks and placing them at an angle of about 45 degrees a little below and to the rear of the upper set, thus relieving the lower cords of a sharp bend which shortens their life and allowing the under jacks to have their tablets marked to correspond with their upper mates and to be always in full view of the chief operator, who can see the tags of both wedge and jack at any angle of observation whilst heretofore he had to place himself exactly in front of the upper jack, run his eye down the straps to find the lower jack and then pull out the wedge to ascertain its number. Those who have worked both systems for a long time say they would not return to the old system on any account.

INSULATED ELECTRIC CONDUCTORS.[1]—III.

BY

James Burstead Williams M.D.

Chapter III.

The replenisher and gauge are secured to the cover, R, of a large glass jar, the lower portion of which is converted into a Leyden jar by being coated inside and out with tinfoil. The replenisher is made like those in the Thomson electrometers, and is always self-exciting. Its inductors form arcs of a circle only three inches in diameter, yet, when the carriers are rapidly rotated by the fingers, a continuous brush discharge three-quarters of an inch long, in air, is produced by it. The gauge is similar to that of the Thomson portable electrometer, the adjustable attracting plate being above an attracted disc. The hair on the forked end of the gauge lever moves between the lines of the II of a small watch dial, this being the nearest substitute for the "two black spots on white porcelain" the writer could procure on the Pacific coast. The replenisher and gauge are mounted in a separate vessel so that they can be used for charging and maintaining at fixed potentials *other* bodies than the needle and jar of the electrometer. When used with the electrometer the electrode, J, of the former is connected with I, the electrode of the needle (and jar) of the latter, and the frames (and outer coatings of the jars) of the two electrically joined together and to the earth. When thus combined, the combination can be used in the same manner, and for the same purposes, as the "White pattern" quadrant electrometer.

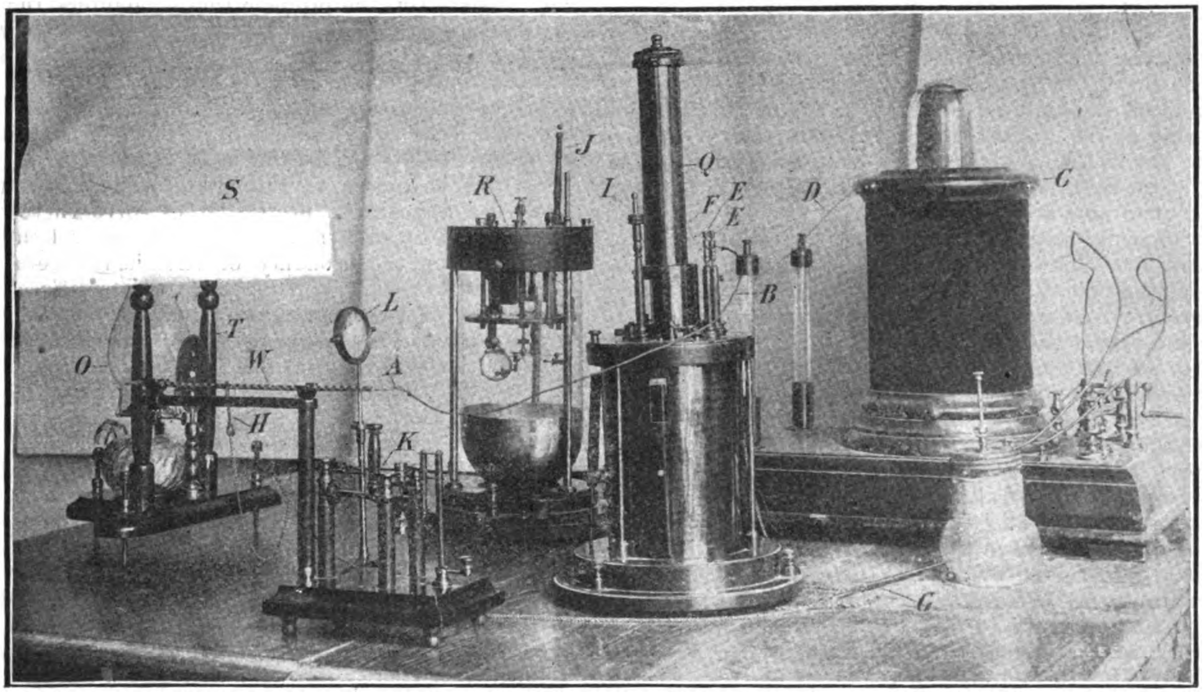
Before entering into the details of factory work, the action of the instruments used for quickly determining the comparative insulation resistances of short pieces of insulated conductors will be described in order that future repetitions may be avoided. The instruments so used were the electrometer with its lamp, scale, shield, and lens, the discharge key, and the coil and cell operating it. The replenisher and gauge, air condenser, and battery were not used with the electrometer, etc., in this kind of testing, but were used when the insulation resistance, in megohms, of certain samples was to be determined. The use of apparatus similar to that last named is explained in text-books, and therefore need not be described herein. This last-mentioned method of testing is not suitable for quick work and, as will be seen hereafter, is not as satisfactory as the one about to be described. The electrometer is first leveled with the leveling screws—the necessary adjustments of the quadrants, etc., having previously been made—and the lamp, shield, T, and lens, L, so placed that the mirror of the electrometer, centre of the lens, hole in the shield, and edge of the flame are practically in the same vertical plane, the lamp being about two feet in front of the electrometer. (See illustration.)

---

[1] *Copyrighted* 1891, *by James B. Williams, M. D. All rights reserved.*

The shield and lens are next adjusted until the image of the cross-wire is well defined upon the scale, S, when the scale is placed as represented. One pair of quadrants, the needle and inner coating of the jar (that is, the acid in the jar), and the induction plate are electrically joined together and to the outer coating of the jar (and frame of the electrometer) by a fine wire fastened to their respective electrodes, and then to earth by a chain, G, or a wire, which is more reliable.

In the illustration, the electrodes of the two pairs of quadrants are represented by E and E′. The induction plate electrode is behind the tube, Q, which covers the mirror and needle suspension, and therefore not visible. F represents the fine copper wire which is fastened to I, E′, induction plate electrode, and frame of the electrometer.



Apparatus For Testing Insulation Resistance of Wires Under High Potentials.

A chain may or may not make a good "ground wire" or other connection for testing apparatus. In *all* cases its conductivity should be ascertained by the aid of a single cell and a "detector"—an electric bell would answer as well—before the chain is used, as a coating of varnish or lacquer on the metal often insulates the links from each other. The links of a bright steel chain will sometimes be so well insulated by an invisible coating of transparent lacquer that even short sparks from a coil will not pass from one end of the chain to the other. Ignorance of this fact caused the writer to make several curious mistakes, when first using the electrometer. We first test the pair of quadrants to be used, and then the discharge key for leakage. The quadrants are fully charged, by sparks, in the manner presently to be explained, to a potential previously decided upon and for which they are adjusted. The scale is then moved to the right or left (depending upon which pair of quadrants is used) until the image of the cross-wire falls upon division 300 of the scale. If the scale were several feet long and properly curved it could remain directly in front of the electrometer, as shown. The ends of the scale should always be equidistant from the centre of the mirror and its centre at the same distance from the mirror as when the spot of light was first focussed upon the scale.

If, when the quadrants are charged to a potential of 3,000 *volts and upwards*, the image of the cross-wire does not fall more than about *one division on the scale in one hour*, their insulation may be considered perfect; but if the fall be greater than this the cause of leakage must be ascertained and removed before proceeding further. The insulation of the pillar mounted on the base of the discharge key is next tested. A bare wire is laid in the U-shaped supports on the horizontal arm, the covered wire, W, and the hook, H, which hangs upon W, having been removed. The wire which has been substituted for W is now connected with one pair of quadrants, by means of a wire joined to it at A and to the electrode of the quadrants, E. The quadrants are next fully charged, as in the first instance, and, as the wire on the arm is connected with the quadrants, it has the same potential as the quadrants. If the insulation of the latter be perfect it is evident that if any leakage occurs—which is known by the spot of light passing down the scale—it must necessarily take place along the pillar. If leakage should occur the pillar must be treated until its insulation *is* perfect.

The next and last thing to be tested for leakage is that pillar of the discharge key on which the top contact—that is, the platinum-tipped screw against which the lever, K, strikes when fully released by the trigger—is fixed. This can be done by disconnecting the wire (from the quadrants) at A, and fastening it in the binding screw at the top contact. Then recharge the quadrants, as before (the lever of the key being depressed), and note whether the spot of light remains stationary after charging. It is obvious that *any* uninsulated body coming in contact with a wire connected with the charged quadrants must discharge them. Instead of disconnecting the wire at A, the hook, H, which is always connected with the top contact of the key by a flexible conductor, is hung upon the bare wire on the arm (the lever of the key being depressed) and the test conducted as above stated.

In a former paragraph it was stated that the scale was moved to the right, say, until the image of the cross wire fell upon 300 when one pair of quadrants was fully charged to the potential for which they were adjusted. But the quadrants may also be so charged that the image will fall upon 200 or any other division we please, the scale remaining in the same position as before. We will first suppose that they are to be fully charged. A wire, D, is fastened to the upper pole of the secondary wire of the coil, say, and the end brought within a short distance of a wire joined to the electrode of the quadrants. The interrupter of the primary circuit of the coil is then adjusted so that when the wheel of the interrupter is revolved by the crank any desired number of sparks is made to pass between the wires just above mentioned, at B, for instance. Whenever sparks pass at B the needle of the electrometer is violently deflected and the spot of light sweeps across and off the scale to the right. If the quadrants have been fully charged by the sparks, the spot of light immediately comes back onto the scale, passes along it to 100, say, then swings to the right again, and so on, the vibrations of the needle becoming quicker and the angular deflection of the image of the cross-wire on both sides of 300 less with each succeeding vibration of the needle until the image finally settles at 300. But if the quadrants have been overcharged by the sparks, *i. e.*, raised to a higher potential than that for which they have been adjusted, the spot of light sweeps across and off the scale to the right, as at first, but instead of stopping at 100 on the return swing it passes off the scale to the left, and after a few vibrations the needle comes to rest in its normal position. It frequently happens that the quadrants are not fully charged by the sparks at the first charging and the image comes to rest at 295, say, instead of 300. The next spark that passes at B will probably raise the potential of the quadrants too high, and they will therefore discharge themselves. Now we can either discharge and repeat the chargings until the image *does* settle at 300, or we can raise the potential of the quadrants in another way. Suppose that, after charging, the image settles at 290, and we wish to bring it up to 300. To do this we take a rod of hard rubber, electrify it by rubbing, and then touch the quadrant electrode with the end of the rod, and repeat the operation of electrifying and touching as often as is necessary.

Again, suppose that we wish to charge the quadrants to a potential represented by 250 of the scale. We charge the quadrants, as before, and the image comes to rest at 260, say. The potential of the quadrants and, of course, any *insulated* body connected with them can then be lowered by degrees by touching the electrode with a small rod of metal fastened in a highly insulating handle—any small "proof plane" would answer as well—then discharging the rod by touching it with the finger, again touching the electrode and discharging, and so on until the image is brought to 250.

We are now ready to illustrate the testing of different kinds of insulated conductors, and will commence with the cheaper grades and show what takes place when such wires are tested at a potential of about 3,000 volts.

Purchase a piece of wire, W, for instance, which is insulated with two layers of cotton saturated with paraffine, place it in the supports on the arm (see illustration) and connect it with the electrode E, as shown. Remove the hook, H, from the wire, W, and then charge the quadrants. It is evident that as long as the insulating layer of W remains in contact with the insulating supports no leakage will occur. But suppose we touch the insulating layer with one finger or any other conducting body having the same amount of surface. We do so and find that the entire charge escapes through that portion of the insulating layer immediately beneath the finger, and the spot of light passes off the scale apparently as rapidly as if the *bare* wire had been touched. We then recharge and touch the insulating layer with a body having a smaller surface then the end of one finger. The charge still escapes. We repeat the process of charging, and touching the insulating layer with a smaller body each time until we find that the charge escapes upon touching the insulating layer with the smallest practical surface, the point of a pin. If we remove the wire, W, and substitute therefor one insulated with one or two braids saturated with almost any of the insulating paints now used and subject it to the same conditions, we obtain precisely the same results.

ECONOMY IN PRIMARY BATTERIES EMPLOYED FOR GENERATING POWER.

BY

A. E. Kennelly

THERE are rules given in several electro-technical textbooks for the determination of the grouping of a given number of cells in a primary battery in order to realize from them the maximum amount of external work. This is the problem that is often presented to the telegraphist who has a number of cells ready at his disposal, and who desires to make the most of their performance under given conditions. But the problem that encounters the investor in a primary battery for the development of power, even on the smallest scale, is:—What is the criterion by which the qualifications of different cells can be judged for the purposes of generating energy? And, having selected the type of cell for a given supply of power:—What number and grouping of cells will be the most economical to employ? So far as is known to the writer, no publication has yet made its appearance professing to solve these problems directly and by rule, although much general information bearing upon the economy of chemical generators, and particularly of secondary batteries, exists diffused through the pages of periodicals and pamphlets; and, in particular, an excellent paper by Prof. F. B. Crocker on "The Possibilities and Limitations of Chemical Generators of Electricity" was read before the American Institute of Electrical Engineers in May, 1888, and in this paper the cost of galvanically developed power is clearly outlined rather from the purely chemical standpoint, than on the basis of existing batteries.

The reason for the lack of information on economical generation of power from batteries is no doubt associated with the fact that the expense of galvanic power has been almost prohibitive in the past for all purposes, and even at the present time the battery cannot possibly compete with the steam engine and dynamo for the development of large quantities of energy, considering that a kilowatt-hour must cost at least ten cents in zinc consumed alone for a battery under the most favorable conditions, while it can be produced for less than two cents' worth of coal burnt under a boiler. In spite of this disparity of cost in material however, the applications of electricity are becoming so numerous that for small supplies of power to drive fans, sewing machines, cautery knives, etc., where the inconvenience and expense of a small engine and dynamo are out of the question, a primary battery may be employed with advantage and economy, and there is at least one battery on the market that will yield a strong current when called upon to do so without appreciable polarization or local action.

This paper is therefore offered for the purpose of presenting succinctly the conditions that determine the economical selection of batteries when the power that they will be required to furnish is known. The results, like all other numerical evaluations, should be regarded as guides, rather than as oracles, since the numerous special conditions that may be contingent to each individual case may often call for a modification of the general rule.

Our first determination may be the minimum number of cells that, having each a definite E. M. F., e, and internal resistance, r, will steadily supply a current of c amperes under a uniform pressure of v volts at battery terminals. Let the total number of cells required be N, and the number of equal rows or series into which these are divided be n.

These conditions give:

$$\frac{Ne}{n} - \frac{N}{n^2} c r = v \qquad (1)$$

and thus
$$N = \frac{v n^2}{en - cr} \qquad (2)$$

It is clear that we can have an infinite number of values for N, one for each value of n which is greater than $\frac{c r}{e}$. If $c r < e$, or the drop in the cell caused by the required current is less than its E. M. F., a single row or series of cells in sufficient number can be made to supply the current, and $N = \frac{v}{e - cr}$ is a possible solution, though not, as we shall see, the most economical solution, unless it so happens that $c = \frac{e}{2r}$. If $c r$ is not less than e then evidently the current cannot be produced by any possible number of cells in one series. It will be necessary to add others in multiple.

Regarding N in equation (2) as the dependent and n as the independent variables, we obtain the minimum value of N by causing the first differential coefficient of N with respect to n to vanish while observing that the second coefficient then becomes positive. If this operation be performed, we find :

The series,
$$n = \frac{2 c r}{e} \qquad (3)$$

The number in each series,
$$\frac{N}{n} = \frac{2 v}{e} \qquad (4)$$

The total number,
$$N = 4 v c \frac{r}{e^2} \qquad (5)$$

As an example, suppose that it is required to produce 10 amperes under eight volts steadily at the terminals of a battery whose E. M. F. is two volts and internal resistance 0.2 ohm per cell.

The minimum number of cells is needed:

Here,
$$n = \frac{2 \times 10 \times 0.2}{2} = 2;$$

and,
$$N = \frac{4 \times 8 \times 10 \times 0.2}{2 \times 2} = 16;$$

so that 16 cells should be used in two parallel series of eight each. The E. M. F. and resistance of each row would be 16 volts and 1.6 ohms; so that, jointly, the battery would have 16 volts and 0.8 ohm and be capable of meeting the specified conditions, yielding eight watts externally at an efficiency of 50 per cent.

As another example, let 15 amperes be required at two volts from a battery of 1.41 volts E. M. F., and 0.3 ohm per cell.

Here,
$$N = \frac{4 \times 2 \times 15 \times 0.3}{1.41 \times 1.41} = 18$$

and
$$n = \frac{2 \times 15 \times 0.3}{2} = 4.5.$$

In this case the results are not whole numbers, and selection has to fall upon the nearest integers by trial. Thus :

Sixteen cells in four series of four give jointly 5.64 volts and 0.3 ohm, supplying 15 amperes at only 1.14 volts ; but twenty cells in five series of four give jointly 5.64 volts and 0 24 ohm, supplying 15 amperes at 2.04 volts with an efficiency of 36 per cent.

It is also evident, on inspection, that whenever formulas (3), (4) and (5) yield integral results and not fractional numbers, the fall of potential in the battery at work will be equal to the external P. D., or that the working efficiency will be 50 per cent. This is also the well-known condition that the output of the given number of cells shall be a maximum. The condition for a minimum number of cells is, in fact, coincident with the condition that those cells shall develop a maximum output, and operate at 50 per cent. efficiency.

Next, suppose that instead of requiring a definite number of volts and amperes, we are content to take the product and specify for this amount of energy without defining the pressure, with a view to ascertaining whether the range of values thus afforded affects in any way the minimum number of cells required. For instance, instead of asking for 10 volts and eight amperes in the last example, suppose 80 watts only to be in demand.

With this object in view, we readily obtain from equation (1), calling P the amount of power desired, stated in watts

$$N = 4 P \frac{r}{e^2}, \qquad (6)$$

which is the same result as that in equation (5).

n is now indefinite. This shows that the total minimum number of cells required for the development of a given power is independent of the pressure, when the supply takes place at battery terminals; and that there are twice as many independent values of n as there are pairs of factors in N; each such combination will supply the same amount of activity with the maximum output, and 50 per cent. efficiency. For instance, let 400 watts be required from cells having each 2.0 volts and 0.1 ohm.

In this case :

$$N = \frac{4 \times 400 \times 0.1}{2 \times 2} = 40.$$

There are eight ways in which the forty cells can be arranged.

1 row	of 40 cells;	E. M. F.,	80 volts;	res.,	4 ohms;	$c = 10$;	$v = 40$;	eff. = 50 %.
2 rows	of 20	“	40 “	“	7 ohms;	= 20;	20;	“
4 “	10	“	20 “	“	0 25 ohm;	= 40;	10;	“
5 “	8	“	16 “	“	0.16 ohm;	= 50;	8;	“
8 “	5	“	10 “	“	0.06254 ohm;	= 80;	5;	“
10 “	4	“	8 “	“	0.04 ohm;	= 100;	4;	“
20 “	2	“	4 “	“	0.01 ohm;	= 200;	2;	“
40 “	1	“	2 “	“	0.0025 ohm;	= 400;	1;	“

Each of these ways complies with the conditions. If, however, N is yielded by the formula in fractional form, an approximation can be resorted to with the addition of a few extra cells. If N is a prime number, then only one single series of this number of cells will fulfill the conditions exactly, but a few more added will generally allow of subdivision into parallels, if desired. All departure from the strict minimum alters of course the efficiency.

We have so far considered the number of cells only, but if p be the purchasing price of each cell, the minimum first cost of a battery that will develop P watts is

$$N p = 4 P \frac{p r}{e^2}. \qquad (7)$$

From this it follows that the electrical value of any cell (assuming the absence of polarization and local action) for purposes of generating power varies as $\frac{e^2}{r}$, for we have seen that the number of cells required is $\frac{4 p}{\frac{e^2}{r}}$. If one type of cell has 0.5 volt and 0.05 ohm while another has two volts and 0.8 ohm, their electrical values will be equal, since the same number of each must be selected in order to develop a given amount of external activity.

This rule is the same as that which governs the rating of dynamos and motors, their relative electrical value depends in every case upon the value of their $\frac{e^2}{r}$, no matter what the nature of the winding in the armature of one, or the nature of the chemicals in the solution of the other ; and $\frac{e^2}{r}$ is the power in watts that would be developed in the armature or in the cell if active on short circuit. Also the maximum output is reached in dynamos, motors, and batteries, when the external and internal activities equate, giving 50 per cent. electrical efficiency, the same rule determining in each case the minimum of plant and the maximum of output.[1] There is this difference, however, that dynamos and motors are worked at a much higher efficiency than 50 per cent. in practice, not only because it is economical to do so, but because they would become too hot if they did not, and the useful output of such machines instead of being 0.5, the condition of greatest output, varies from, say, 0.25, with 75 per cent. electrical efficiency in the smallest dynamos or motors, up to 0.02 with 98 per cent. of electrical efficiency in large multipolars. The practice with batteries has hitherto not been in the direction of such high efficiencies, and there is usually no danger of overheating them.

Again, the economical purchasing value of machines and batteries, depends so far as electrical qualifications are concerned on the value of the fraction $\frac{e^2}{pr}$ or what might be termed the short-circuit activity per dollar of cost. Two types of cell, one having an E. M. F. of 2 volts, and a resistance of 1 ohm costing $1, and the other 0.7 volt and 0.05 ohm costing $1.50, would compare in economic value for the production of power in the ratio of $\frac{4}{1}$ to $\frac{0.49}{0.075}$, or as 4 to 6.5, and the installation cost with the latter type would therefore be only 61 per cent. of that with the former for any specified activity, while independently of cost, the electrical values of the two would be in the ratio of $\frac{4}{1}$ to $\frac{0.49}{0.5}$, or 4 to 9.8. That is to say, the cell of lower E. M. F. would, by reason of its more than compensatingly lower resistance, be equivalent to nearly 2½ cells of the two-volt type.

It frequently happens that a type of cell is made in several sizes at different prices, allowing a certain range of selection as to ampere capacity. In such cases the economic first cost value, or watts on short circuit per dollar will generally vary, and that size which makes this number a maximum is the most economical to employ, other things being equal. In regard to cost of operation and maintenance, however, the ampere-hour capacity and lifetime have to be taken into separate account. Thus, in the case of two sizes of one type of cell, each having 2.0 volts, but the first with 0.9 ohm resistance costing $1, the second having 0.3 ohm and costing $1.75, the economic value of installation would compare between them in the ratio of $\frac{2 \times 2}{1 \times 0.9}$ to $\frac{2 \times 2}{1.75 \times 0.3}$, or 4.44 to 7.62; and 44 of the larger cells would represent in value 76 smaller, while independently of cost, the equivalents being $\frac{2 \times 2}{0.9}$ to $\frac{2 \times 2}{0.3}$ or 4.44 to 13.3, one large cell would replace three small ones.

Hitherto we have devoted attention to minimum first cost, but may now consider the conditions that regulate the economy in the total cost of operation. If p be, as thus far assumed, the purchasing price of one cell, then the annual interest and depreciation on this price can be estimated. Call this sum s (dollars). Also from the capacity of the cell in ampere-hours and the cost of renewal, supposed known, find the cost of an ampere-hour in labor and material. Let this sum be denoted by q (dollars). Let h be the number of hours during which the battery is supposed to work at full load during one year. Then if O be the total annual cost of operation we have

$$O = Ns + \frac{N}{n} chq. \tag{8}$$

Substituting the value of N from (2) we find

$$O = vn \left(\frac{ns + chq}{en - cr} \right). \tag{9}$$

Differentiating for a minimum it follows that

$$N = \frac{vcr}{e^2} \frac{(1+a)^2}{a} \tag{10}$$

$$n = \frac{cr}{e} (1+a) \tag{11}$$

$$\frac{N}{n} = \frac{v}{e} \frac{(1+a)}{a} \tag{12}$$

where a is the positive value of the surd quantity $\sqrt{1 + \frac{eqh}{rs}}$

Consequently,

$$O = \frac{vcrs}{e^2 a} (1+a)^2 + \frac{vchq}{ea} (1+a), \tag{13}$$

and since the total number of watt-hours supplied in the year is expected to be vch, the cost per watt-hour w is

$$w = \frac{O}{vch} = \frac{rs(1+a)^2}{e^2 ah} + \frac{q(1+a)}{ea}, \tag{14}$$

while the efficiency of delivery is $\frac{a}{1+a.}$

Equation (14) is as fundamental in the theory of economy of operation as the criterion $\frac{e^2}{pr}$ is vital in questions of first cost. It shows that when h becomes large, that is to say, when the battery is worked much and continuously, the first term in the cost diminishes in importance compared with the second, and the cost of a watt-hour tends to approach the limit $\frac{q}{e,}$ the efficiency tending at the same time to a high value. With batteries worked discontinuously and for short periods at a time, the criterion of economic value in operation tends to the fraction $\frac{e^2}{rs}$ or, what serves the same purpose in nearly every case, the $\frac{e^2}{pr}$ already found for first cost. On the other hand, for long and steady work in batteries the criterion tends to the fraction $\frac{e}{q}$ and so long as the internal resistance does not become unreasonably high, the E. M. F. of the cell per dollar of one ampere-hour's renewal becomes the leading factor. It so seldom happens in practice, however, that batteries are employed in long-continued hard work, that the latter criterion is seldom needed, but it is obvious that the more work is demanded from a battery in a given time the more economical it becomes to add to the first cost by more parallel series of cells reducing the joint resistance, and increasing the efficiency of delivery, which is in all cases measured by the ratio $\frac{vn}{Ne.}$

As an instance, suppose that eight amperes are needed during 100 hours in a year under a pressure at terminals of 16 volts from cells having 1.6 volts and 0.2 ohm each, their price $1.50, interest plus depreciation being 13⅓ per cent. per annum and the cost of renewals estimated at $0.0048 per ampere-hour per cell.

Here $v = 16$, $c = 8$, $e = 1.6$, $r = 0.2$, $q = 0.0048$, $s = 0.2$.

$$a = \sqrt{1 + \frac{2 \times 0.0048 \times 100}{0.2 \times 0.2}} = \sqrt{25} = 5.$$

$$n = \frac{8 \times 0.2}{1.6} (5+1) = 6\,; \quad \frac{N}{n} = \frac{16}{1.6} \times \frac{6}{5} = 12$$

$N = 6 \times 12 = 72$; efficiency $= \frac{5}{6} = 83\frac{1}{3}$ per cent.

E. M. F. of battery 19.2 volts; joint resistance, 0.4. ohm; drop of potential, 3.2 volts; cost of battery, $108; annual cost (interest and depreciation), 14.40; ampere-hours supplied, 800 from 12 sets, or 9,600 cell ampere-hours; cost of renewals, $46.08; total annual cost, $60.48; power, 128 watts; total work done, 12,800 watt-hours; cost per watt-hour, $0.004725.

---

[1] The addition of field excitation, and the variation in the ratio of insulation thickness to diameter of conductor in different windings for an armature, introduce disturbing elements into the strict rating of a dynamo by its $\frac{e^2}{r}$. The rule is, however, sufficiently accurate for all ordinary purposes.

By formula, cost per watt-hour,

$$w = \frac{0.2 \times 0.2 \times 6 \times 6}{1.6 \times 1.6 \times 5 \times 100} + \frac{0.0048 \times 6}{1.6 \times 5} = 0.001125 + 0.0036 = 0.004725.$$

If the most economical installation, only, had been sought for, formulas (3), (4), and (5) give

$$n = \frac{2 \times 8 \times 0.2}{1.6} = 2; \quad \frac{N}{n} = \frac{2 \times 16}{1.6} = 20; \quad N = 20 \times 2 = 40.$$

E. M. F., 32 volts; resistance of battery, 2 ohms; first cost, $60; annual cost, $8.0; total ampere-hours, 800, from 20 sets, or 16,000 cell ampere-hours; cost of renewals, $76.80; total annual cost, $84.80; work done, 12,800 watt hours; cost per watt-hour, $0.006626.

Thus far we have supposed that the power to be utilized was taken at the battery terminals, or that if leads were taken from the battery to the work, the resistance of those leads was negligibly small. It becomes desirable to ascertain in what degree the conclusions already reached are affected by the introduction of sensible resistance in conductors that may intervene between battery and delivery.

Calling the resistance of the two leads together, t, equation (1) becomes:

$$\frac{N}{n} e - \frac{N}{n^2} cr - ct = v, \tag{15}$$

and the solution for this for a minimum in N gives:

$$N = 4\,c\,(v + ct)\,\frac{r}{e^2} \tag{16}$$

$$\frac{N}{n} = \frac{2\,(v + ct)}{e} \quad (17) \qquad n = \frac{2\,cr}{e} \quad (18)$$

These equations show that as regards first installation, for given values of v, c, and t, the electrical value of the cell is subject to the same criterion as in previous cases, namely, $\frac{e^2}{r}$, and since the cost of the battery will be Np, the economic first cost value of the cells is determined by the fraction $\frac{e^2}{pr}$, as before. It is evident, however, that the total number of cells required is no longer independent of the pressure, as was seen to be the case when no resistance existed in the leads, and the loss of energy in any given pair of conductors will be increased by lowering the pressure of supply. Formulas (16), (17) and (18) give, however, the minimum number of cells and thus the minimum outlay when the pressure and current are specified through leads of known resistance.

Taking, for example, the first case mentioned, of 10 amperes needed at eight volts with cells of two volts E. M. F. and 0.2 resistance, but with leads in circuit whose resistance t is 0.2 ohm, we have:

$$N = 4 \times 10\,[8 + (10 \times 0.2)] \times \frac{0.2}{2 \times 2} = 20;$$

$$n = \frac{2 \times 10 \times 0.2}{2} = 2.0$$

and 20 cells in two series of 10 each, will fill the requirements and represents the minimum outlay.

As regards economy in operation, there is no difficulty in extending the above processes to determine the number of cells and the size of conductors that shall make the total cost of operation a minimum, but the formulas become so complex that there is no practical advantage in developing them. It is evident, however, that since power from a battery is expensive, relatively, it becomes economical to employ heavy leads and by some extra first cost in conductors keep the loss in transmission as low as possible. It also becomes possible to reduce the case of economy of operation through leads, to economy of operation without leads, at least for uniform load, by adding to the power absorbed in the motor or other working device, the power that will at the full load current be lost in selected conductors, and assuming that the sum of these two is power taken at battery terminals as before.

To sum up, we have examined the conditions that regulate the economy of installation and of operation in batteries intended for a prescribed amount of work. The space that a battery will occupy, the attention that it may be expected to require, its local action, and polarization, are all factors that have to be taken into separate account for each individual case, but the following leading facts are to be recognized.

1. The electrical value of a cell for doing work is measured by its $\frac{e^2}{r}$ or, the power in watts it can expend internally when short circuited.

2. The economical value as regards first cost and installation of a cell for doing work is measured by its $\frac{e^2}{pr}$ or the power in watts on short circuit per dollar of price.

These rules hold whether there is sensible resistance in the leads or not.

3. The conditions of minimum installation and minimum first cost involve those of maximum output, with a working efficiency of 50 per cent.

4. The economic criterion of a cell as regards operating expenses depends upon the continuity or intermittence of its work. For light work it is measured by $\frac{e^2}{pr}$ or watts on short circuit per dollar of price as in the case of first cost. For heavy, sustained work the criterion becomes $\frac{e}{q}$, or the E. M. F. of a cell per dollar of renewal expense on one ampere-hour. For any given case the comparison can be effected by formula (14).

To find the minimum installation and first cost for a given power with negligible resistance in leads, formulas (3), (4), (5) and (6), may be used.

If minimum cost of operation is sought for and not minimum first cost, formulas (10), (11), (12) and (13) apply, with the addition to the power needed of the power lost in leads, if these have sensible resistance. The minimum installation for the case of leads having sensible resistance is specially dealt with in formulas (16), (17) and (18).

THE PRACTICAL MANAGEMENT OF DYNAMOS AND MOTORS.—VIII.

BY

Francis B. Crocker and S. S. Wheeler.

Chapter VI.

DIRECTIONS FOR STOPPING DYNAMOS AND MOTORS.

This is accomplished by following substantially the same rules as those given for starting dynamos and motors in Chapter IV., only in the reverse order. But there are certain peculiar points to be observed in each case; so, in order to avoid any possible mistake, the matter of stopping is treated in this separate chapter. After any machine is stopped it should be thoroughly cleaned of dirt, copper dust and oil and put in perfect order for the next run. Switches, brushes, etc., should be fixed so that they will not accidentally close the circuit.

***One Constant Potential Dynamo* (*Shunt, Series or Compound Wound*)** running *alone* on a circuit with no danger of receiving current from any other dynamo or battery, should be slowed down and stopped without touching the switches, brushes, etc., in which case the E. M. F. and current decrease gradually to zero as the speed goes down. The switches may then be opened and the brushes lifted without any spark. In the case of copper bushes this should be done just before the machine stops entirely, in order to avoid any injury to them if the machine turns back a little as sometimes occurs. Never switch out or disconnect a dynamo at full or even partial load except in extreme emergency, and the brushes should never be raised while the fields are strongly magnetized as the discharge of the magnetism may break lamps or pierce the insulation.

Dynamos in Parallel.—To stop a dynamo running in parallel with one or more others or with a storage battery on the same circuit (usually constant potential) regulate down its E. M. F. until it is only slightly greater than that of the circuit (about one per cent.) and its ampere meter shows that it is producing very little current; the switch connecting it to the circuit should then be quickly opened. Under no circumstances, however, should a dynamo in parallel with others or a battery be stopped, slowed down or have its field magnetism discharged or weakened (*i. e.*, more than enough to regulate its E. M. F. as stated) until its armature is completely disconnected from the circuit, as it might be burnt out or driven as a motor if its E. M. F. fell more than a few per cent.

Compound Wound Dynamos in Parallel may be stopped by exactly reversing the method for starting (Fig. 13) but if as there suggested the "equalizer" (E, Fig. 13) is left closed all the time the machines may then be stopped like simple shunt machines in parallel, as just described.

Dynamos on the Three-Wire (Direct) System are also stopped like dynamos on any constant potential circuit as explained in the chapter on starting.

Constant Current Dynamos and Motors in series may be cut out of, or into, the circuit without trouble and may be slowed down or stopped without disconnecting them from the circuit as the current is limited. If desired, the field coils may be short circuited to stop the action of the machine while in circuit. The only precaution, and that is absolutely imperative, is to maintain the *continuity* of the circuit and never attempt to open it at any point as it would cause a dangerous arc. Hence a constant current machine must be *cut out* by first closing the main circuit around or past the machine and then entirely disconnecting it from the circuit, that is, both its wires or terminals.

One Alternator running *alone* on a circuit may be stopped or the field current shut off without trouble.

Alternators in Parallel may be disconnected from the circuit without the difficulty which is found in throwing them on, because it is not necessary to get them in phase.

A Constant Potential Motor is stopped by turning the starting box handle back to the position it had before starting (Fig. 17) or if there is a switch connecting motor to the circuit it may be opened. In the latter case a considerable spark will occur, but if it is a "quick-break" switch it may be better able to stand the spark than the starting box. The strictly best way is to turn the starting or regulating box arm back to the last contact point, which puts all the resistance in circuit, and then open the quick-break switch.

Either of these three ways is perfectly safe and the one may be adopted which trial shows to work best and burn contact points the least. A constant potential motor like the corresponding dynamos when in parallel, should never be stopped or much reduced in speed or have its field discharged or weakened until it is disconnected from the circuit, otherwise its counter E. M. F. is not enough to prevent an excessive current from rushing through its armature.

Thus it will be seen that the constant potential machine is exactly the opposite of the constant current. The former is safest when the circuit is open and it is very bad to short circuit or stop it with the current on, whereas the latter is safest when the circuit is closed, and the machine may be stopped or short circuited while in circuit. In the latter case a dynamo would require an effective regulator.

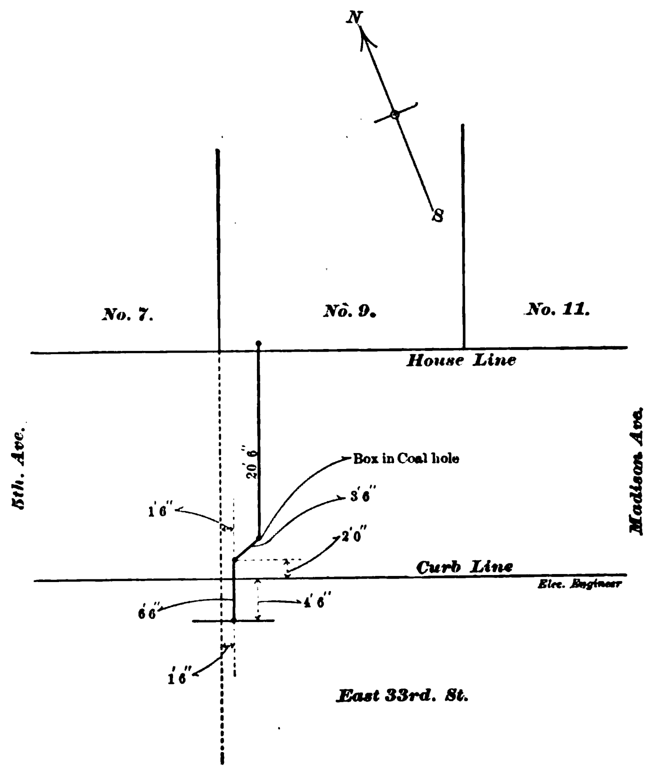
PUTTING IN A HOUSE SERVICE FROM THE EDISON THREE-WIRE SYSTEM.

BY

H. Frank Korthener.

The three-wire system of underground tubing and boxes used by the Edison Electric Illuminating Company, of New York, is familiar to all, but the work of putting in a service or stub from the main, laying a new line, or repairing a "burn-out," may not be so generally known.

This work is done by one of the gangs of men in the employ of the company. A gang consists of a foreman, tester, jointer and a number of laborers. Before the work can be commenced, a permit must be obtained to tear up the street; a "location" is also sent from the office. This location is a map of the street in front of the house in which the service is to be put, and shows the position of the line and nearest boxes.



Putting in Edison 3-Wire House Service.

The service is laid from the nearest box; if this box is near enough to the cellar of the house a tunnel is dug to it from the cellar; if it is not, a trench must be dug in the street and across the pavement. When this is done, the necessary measurements are taken in the trench for the length and direction of the tubing required, and some of the men are sent to the company's yard to get the pieces wanted.

Then the jointer takes off the "box" on the main line, and cracks off the hard compound filling it, which encloses the copper wires, or "coppers" as they are called. The compound left sticking to the coppers is melted off, and they are then wiped and cleaned.

After the tubing has been brought and laid in the trench, it is tested, before being joined up. The testing arrangement consists of a portable astatic galvanometer, a 50-cell chloride of silver battery and a set of leads. The leads are made of two conductors of flexible lamp cord, drawn into a piece of soft-rubber tubing about six yards long. The galvanometer and battery are set up on the sidewalk, and the leads reach in the trench to the pieces to be tested. The battery and galvanometer are connected in series and if there is no deflection of the needle of the galvanometer when the leads are put on the tubing, the piece is "O. K."

In testing the pieces, one of the leads is put on the iron tube, and the other on each of the three coppers in succession. Then the leads are put on the first and second coppers, first and third, and second and third coppers. Then the needle is allowed to swing off by holding the bare ends of the leads in the hands, to show if everything was in working order when the test was made.

After the pieces have been tested they are joined together with flexible wire joints and the boxes are bolted on. Then the last joint, on the main, is made; this is generally a "live" joint and some caution must be observed in soldering, not to have the solder short-circuit the coppers. The jointer must be still more careful in some cases, where, in order to get at the box, he must crawl his whole length in a tunnel barely large enough to admit his body.

When all the boxes are on they are filled with hot compound and closed up. The compound, when it cools, hardens like pitch and forms an excellent waterproof insulator. Before the boxes are covered over with earth they are located by the tester in the manner shown in the accompanying sketch. A box is generally located in two ways; first, by the perpendicular distance in, or out, from the line of the curb; and, secondly, by the perpendicular distance from the nearest house line between two houses, the house line being supposed to continue into the street. A drawing of the location and notes upon it, are entered in the tester's "field-book." Slips are made out by the tester giving the district, street, side of street, house number, length of service, size of tubing, date, foreman's name and tester's name. This slip also contains a drawing of the location and is sent to the office when the permit is returned.

When the boxes have been located the trench is filled up and the pavement and sidewalk replaced. The work is now finished and it is only necessary to connect the house wires and meter to the service for the consumer to obtain light or power.

TELEPHONIC PROGRESS IN AUSTRIA.

THE telephone in Austria, according to the London *Electrical Engineer*, continues to make steady progress. The subscribers in Prag, Trieste, Lemberg, Graz, Czernowitz, Pilsen, Reichenberg, and Bielitz, have increased to 3,624, and in Vienna to 5,200, and in the 47 small exchanges opened by the Government since 1889 to 1,716, a total of 10,540. In Vienna the majority of the lines are underground loop lines; reckoning these as single, there are now 12,250 miles laid, and 9,500 being laid. The total telephonic wire mileage for the country amounts to 25,800. The cables used in Vienna are 1 mm. copper wire, covered with 1 mm. gutta-percha. There is only one exchange in Vienna into which now 5,000 looped lines run, and about 3,000 more are being run into it to provide for future extensions. The most distant subscriber is some four miles from the exchange. Interurban trunk lines have also been pushed forward; there are now 23, of which the most important are: Vienna-Prag (direct), 191 miles; Vienna-Prag (*via* Brünn), 219 miles; Vienna-Brünn (direct), 79 miles; Vienna-Budapest (three lines), 250 miles; Prag-Tilschen, 72½ miles; Prag-Reichenberg, 70 miles. The Vienna-Trieste line will be commenced in March *via* Graz; it will be 313 miles long.

ECONOMY IN ARC LIGHT WIRING.

BY

H. B. Rommel

I HAVE noted with interest the suggestions made by Mr. Sharpsteen on arc light wiring in THE ELECTRICAL ENGINEER of March 16, and fully appreciate the necessity of economy in this direction. From time to time we hear of many plans for reducing the amount of copper on our incandescent circuits, but the question of reduction on arc circuits seems to have been sadly neglected by our electrical engineers. While economy in the former instance is no doubt the most desirable, we still find a large field for improvement in the latter, which means less capital to the investor and a corresponding reduction in the amount of line repairs.

The plan used by Mr. Sharpsteen would be of value in but very few instances as, in order to effect any saving in wire, both municipal and commercial lights must be located on, or very near, the same street. In the majority of cases, however, it is found necessary to string one line through one street and return by another. This would necessarily cause a constant return of the line to either street in order to keep the commercials in rotation, and would consume more wire, and require more poles, in many instances, than by running an entirely separate circuit.

The objection to wasting power, caused by starting municipal lights at the same time as commercials, raised by Mr. Sharpsteen, is to the majority of electric light superintendents the least consideration, as on nearly all circuits single-carbon lamps are used for commercial lighting, and in many cases the consumer neglects to turn out his lamp when business hours are over and at the time contracted for. The lamp then, on burning to the full length of the carbon, cuts itself out automatically, but still has the full current traveling through its magnet coils; and this is not only detrimental to the adjustment of the lamp, but to the life of the coils themselves. Here we have another and greater loss of power caused by the lamp burning from the contract time to the point of cut-out, as well as materially injuring the mechanism; and in order to obviate these difficulties it is absolutely necessary to control our commercial lamps from the station. I have made it a point, of recent years, to place a short-circuiting switch in addition to the ordinary cut-out within easy reach, and the result has been more than encouraging; the switches saving over and over again their original cost in power and life of lamp.

To my mind the advancement of economy in arc wiring lies more in the direction of a single circuit from which all commercial and municipal lamps can be turned off and on by an automatic cut-out operated by battery from the station. This automatic cut-out will take the place of the ordinary cut-out, and the amount of wire necessary to operate them will be a comparatively small item. We find just such an automatic switch employed for incandescent work, and illustrated in the same issue of THE ELECTRICAL ENGINEER; and it is but a question of a short time when this plan will be adopted for arc circuits, thus materially reducing the consumption of copper by local electric light companies.

SERMONS BY TELEPHONE.

THE TELEPHONE COMPANY of Glasgow has completely fitted up an elaborate telephonic arrangement in Woodside Church, whereby the subscribers are enabled to hear the entire service at home with the utmost distinctness and ease.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, MARCH 30, 1892. No. 204.

Truisms which one has verified for one's self out of a personal experience, are apt to have a special value to the owner.—Prof. S. P. Langley.

OIL AS AN INSULATOR.

IT may be laid down as an established fact that the creation of a new art is accompanied almost invariably by developments in collateral lines and the employment of methods and apparatus in a practical way that had up to that time been used merely experimentally. The recent enormous impetus given to high tension transmission is no exception to this rule, and those who have followed the course of recent events must be thoroughly impressed with the important position assumed by oil as a means of insulation. The results obtained in the Lauffen-Frankfort transmission have already given indication of the value of oil as an insulator for overhead lines and in that respect had only tended to confirm the results already obtained with it on circuits of comparatively low potential difference. Mr. Tesla and Prof. Elihu Thomson had also demonstrated its value as an insulating medium for high tension currents, and, in general, for the insulation between primary and secondary coils of converters. As regards the history of oil as an insulator we note that in an excellent paper read before the Institution of Electrical Engineers, Prof. D. E. Hughes, lays claim to having first employed it in this manner, and in substantiation thereof cites the patent issued to him on Jan. 11, 1859. But it is the results obtained by Prof. Hughes which he gives in his lecture to which we would rather draw attention, and which prove unquestionably the great superiority of oil over even the best of solid insulators heretofore employed, not excluding gutta-percha. Prof. Hughes shows in effect that the value of oil as an insulation increases both with the potential of the charge and also with the rapidity of alternation; for when the experiments are made by an impulsive rush so as to have the greatest number of vibrations per second, in the neighborhood of one million, even the poorest oil, such as castor oil, shows marked superiority over air or gutta-percha, a behavior which recent investigations have shown to be in direct contrast to that of solid insulation material. Prof. Hughes also showed that a spark from a Leyden jar which would usually pierce four inches of air would not pierce one-nineteenth of an inch of rosin oil, proving that oil when resisting an impulsive rush has seventy-nine times higher insulating powers than air.

But there is another application of oil insulation, pointed out by Prof. Hughes, which ought to receive the most serious consideration by manufacturers of submarine and underground wires, and that is, the remarkable power of self-restoration when the insulation is temporarily destroyed by a puncture or cut so as to lay the wires bare for an instant. As an example of this, Prof. Hughes showed a thinly coated gutta-percha wire plunged into a small lead tube containing rosin oil. A cut through the gutta-percha, laying bare the wire, destroyed the insulation for an instant, but in less than a second the oil percolated through the cut and restored the insulation to its previous high value. The prescience of Mr. David Brooks and his steadfast advocacy of oil insulation, entitle him to be recognized as a pioneer in this field. In this connection the insulators described by Mr. Hewett in another column would appear to fulfil the conditions suggested by Prof. Hughes in constantly providing a fresh insulation for underground bare conductors.

But there is one aspect of the question of oil as an insulator which must not be lost sight of, if we apply this method to telegraphic, and more specially to telephonic and to high tension work. We refer to the high specific inductive capacity of the oils in general, that of rosin oil being equal to, if not greater, than that of gutta-percha. The effect of this increase in capacity in telephone cables must necessarily shorten the effective talking distance to a very large extent; indeed, so narrow is the margin here permissible that dry-paper insulation may now be said to have become the standard of American practice, and involving a capacity of .075 microfarad per mile, as against .30 for gutta-percha. The effective capacity of the line in high tension alternating work was only too well shown in the Lauffen-Frankfort transmission, where a large part of the power was absorbed in charging the line alone. It may be argued that this charge is one which is constantly restored, and hence entails no expenditure of power, but it would still entail an increased capacity in the generating apparatus for a given power to be delivered at the other end of the line. It is not, improbable, however, that difficulties in this direction may, in the future, be overcome by counteracting devices involving auxiliary condensers and coils with high self-induction. There can be no reasonable doubt that while the solid insulators still have a large field of usefulness before them the liquid insulators will occupy a prominent position in the future in high tension electrical work. Before the employment of oil becomes general, much will have to be done in studying its actions, especially when used in connection with fibrous and other insulating materials. In the excellent series of articles by Dr. J. B. Williams, now appearing in our columns, special reference will be made to this important and timely subject.

THE ADVANTAGES OF A BUGABOO.

Twice within a few weeks we have been appealed to by readers to make some effort by way of stopping the spread of the reckless habit into which newspaper reporters, and some insurance people, have fallen of ascribing every mysterious fire to electric wires. One recent instance occurred in New England, and another happened at the destruction of the Smith-Gray building in Brooklyn, when the fire was attributed to electricity, although the owner, who ought to know something about the matter, said that the idea was perfectly absurd. In our current issue appears a letter from St. Louis protesting against the reports of the fire in the Liggett & Myers building, on the very reasonable ground that there was not a wire within 40 feet of the place where the fire broke out.

So far as the newspaper men are concerned, we can only advise our friends to have patience. Newspapers are generally open to the argument of facts, and in due course they will learn that while electricity has its dangers, it is the *safest risk*. Insurance companies know this, but in the gradual introduction of electricity they see the opportunity to advance, piecemeal, their present low rates of insurance, so that by the time all good buildings have electricity, everybody will be paying higher rates. There may be no defined plan about this, but there is beyond question a tendency of the kind suggested. Our insurance contemporary, *The Standard*, of March 19, in a leading editorial says: "Electricity is recognized as a bad hazard, but with approved lighting installation *is placed ahead of kerosene or gas*." Here again, however, the drift of policy we have referred to is shown for it is added: "A charge is very properly made where the electric trolley wire is used for street car service." Now last week, we pointed out that 87 per cent. of the cities over 200,000 inhabitants, in this country, and 97½ per cent. of the cities between 50,000 and 200,000, have trolley roads. Are we to infer that in every one of these a building whether it has outside connections or not, is "properly" liable to an extra charge? If so, anybody can see at once that an enormous percentage of insurance comes at once under heavier assessment, although it has a form of lighting that "*is placed ahead of kerosene or gas*." We may note that the addition on account of trolley systems is 2 cents. We also note that, in spite of the statement or admission in *The Standard*, the new schedule submitted by the underwriters to the companies assumes that the "standard building" is lighted by gas, and provides that even where the electrical installation is approved, 1 cent shall be added for electric lighting. In other words, electricity is a convenient bugaboo for squeezing an extra 3 cents out of insurers. We agree with our correspondents that it is time a kick was made.

THE COST OF CURRENT FROM BATTERIES.

In spite of the almost universal employment of the dynamo as a current generator, the galvanic battery still has a large field of usefulness which it is likely to enjoy for some time to come. To discuss its economic value, therefore, is opportune, and the discussion is valuable when taken up on the lines adopted by Mr. A. E. Kennelly on another page. The author shows in general the marked influence of the internal resistance on the working economy of a galvanic battery, not only from the electrical standpoint, but also when considered as a factor in relation to the cost of cells to obtain a given power, so that under certain conditions a high voltage cell may be less economical than one of lower voltage having low internal resistance. Mr. Kennelly points out, in addition, the various conditions governing minimum first cost of installation and minimum cost of operation, a relation which has probably never been clearly pointed out in connection with primary batteries.

FENDERS FOR ELECTRIC CARS.

It is interesting to note in the annual report of the Massachusetts Railroad Commissioners the statement that no fender has yet been found which is efficient for the saving of life. Some fenders have been tried since the introduction of electric cars, but the results are not satisfactory; on the contrary, the fenders appear to have been in more than one instance an additional peril to the person who has had the misfortune to get under an advancing car. It would seem that the invention of a satisfactory fender ought not to be difficult, but the fact that cable cars are still without them indicates that the invention has not been made. Cable cars are much more dangerous than electric if only for the reason that their direction of travel cannot be reversed. The probability is that as people become accustomed to the swifter motion of mechanical cars, they will cease to gauge them by the slower standards of animal cars, and then there will be fewer accidents. But of course the greatest safety can only be attained by having the tracks above or below the surface of the street.

HIGH FREQUENCY DISCHARGES.

The extraordinary enhancement of high tension discharges when accompanied by high frequency of alternation is shown in a most marked degree by the experiments described in another column by Prof. Elihu Thomson. These very interesting experiments also show in a striking manner the influence of the number of primary turns on the rate of oscillation, so that a given condenser requires a primary in unison with it to obtain the maximum effect. The importance of large, smooth surfaces to resist puncture in oil and air with such potentials is also pointed out.

ECONOMY IN ARC LIGHT WIRING.

The communications which appear in our columns this week would seem to show that arc lighting practice is still far from that condition which incandescent work has attained where economy in wire is concerned. The methods for securing a saving of circuit as shown in our March 16 issue by Mr. Sharpsteen and in to-day's by Messrs. Young and Mackie are based on different principles and are well calculated to constitute a good basis of comparison for arc light station managers. A suggestive discussion of the subject is also furnished by Mr. Rommel, a practical central station manager. Now that prices for street lights are cut down so near the point of unprofitableness, these methods of economizing in circuit construction, or in operating expense, become more and more worthy of attention.

ECONOMY IN ARC LIGHT WIRING IN NEW YORK CITY.

BY

C. J. Young.

The article by Mr. S. H. Sharpsteen in The Electrical Engineer of March 16, 1892, will no doubt be favorably received by the superintendents of arc light plants, and while there has been but little said of the economy in wiring, as practiced in such plants, still there has been advancement made in the saving of wire and circuits in some of the recent arc light plants installed, and for the benefit of the large majority of central stations it is hoped that others will contribute information, and bring up the standard of economy in arc light wiring to a favorable comparison with the best practices known, for the distribution of power and incandescent lighting on the constant potential systems.

It would be interesting to determine the exact saving as shown in the scheme proposed by Mr. Sharpsteen; for if there happened to be more commercial than city lamps on the 3-legged circuit, the extra cost of the third leg might be more than the saving of coal effected by starting the city lights later than the commercial. However, the idea of the third leg is of value and can be used to great advantage in many cases.

There are many disadvantages in running the dynamos in series, and therefore, where a circuit has as many as 100 arc lamps connected and the dynamos are of 50 lights capacity, a third leg connecting the middle point in the circuit and running back to the station and used as a common return wire for the two 50-light dynamos, allows city lights to be connected on one positive leg, and the commercial lights to be connected on the other positive leg, and they can therefore be started and stopped independently of each other; or all lamps to be operated until midnight may be connected on one positive leg, and the "all-night" lights connected on the other positive leg, and thus two arc circuits can be operated independently of each other and with but three wires.

I may instance a case where this idea was put to good use in New York City, where a company is operating two stations, one down-town and the other up-town, the two stations being connected by a trunk line which operates some of the up-town station circuits from the down-town station, and also commercial lights between the two stations. The remaining circuits were operated from the up-town station. On account of the pressure of business the writer designed the scheme shown in Fig. 1, which allowed of the operation of three dynamos on two circuits, each dynamo being independent, and entailed no increase in voltage, as would have been the case were the dynamos connected in series.

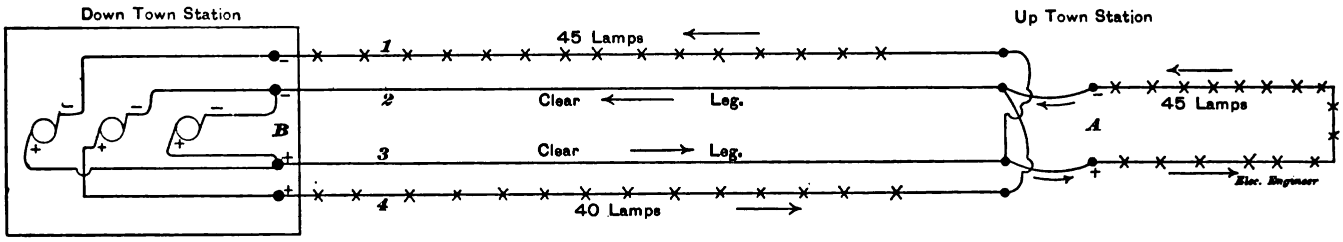

FIG. 1.

This arrangement allowed of the saving of two wires between station B and station A, a distance of six miles, *i. e.*, 12 miles of wire. Of course, it will be readily understood that the legs 2 and 3 carry twice the current of legs 1 and 4, being required to take the current of lamps emanating from station A, in addition to the current for the lamps in legs 1 and 4. The actual current in 2 and 3 was 20 amperes, the normal current being 10 amperes. The wire was No. 6 B. & S., and proved quite ample for this purpose.

Another case where the 3-legged circuit was adopted, was for the operation of (1) a continuous day and night circuit, (2) a day circuit only, and (3) a city night circuit, all three services carried out with the use of but three wires. As shown in Fig. 2, all of the day service was connected in the leg marked r, all the continuous service customers requiring current 24 hours daily connected in leg marked A, and city lights and night service customers connected in leg marked C, one dynamo only being employed. During the day the dynamo was connected with A and B, and at 6 P. M., the dynamo cable was transferred from B to C, and again in the morning replaced in B. For the safety and protection of the day trimmers, a switch was placed at S, which was required to be disconnected in the morning before trimming, and again thrown on after all lamps were trimmed. In this case the amount of wire saved is equivalent to three conductors equal in length to the distance between B and S. This system of circuits, though now discontinued, was found flexible and economical, and if well managed is simple and safe.

TESLA APPARATUS.

A Tesla experimental apparatus is being constructed for lecture purposes at the Finsbury Technical College, says the London *Electrical Engineer*. The students will be very much on the *qui vive* the first time Dr. Thompson ventures to take the million-volt shock into his body. Some one must evidently follow suit to Mr. Tesla, but we have heard the opinion expressed by several engineers that they would hardly like to build and test such an apparatus with a trust in its harmlessness merely from abstract or mathematical reasoning without trying it, say, on a calf first. Mr. Tesla has a splendidly-equipped laboratory in New York, and the experiments he showed at the Royal Institution are by no means all he had to produce, given more accurately determined conditions.

MUNICIPAL LIGHTING IN CHICAGO AND ELSEWHERE.

BY

M. J. Francisco

My attention has been called to a paper by M. H. Mikkelsen on "Electric Street Lighting in Chicago," which is being widely circulated by the advocates of municipal ownership. The author is evidently a votary of municipal ownership and cites Chicago as a shining example of remarkable success financially, and especially calls attention to the fact that the city is "free from the influence of Federal politics."

It is a peculiar coincidence that this laudation of Chicago's aldermen should be followed by Associated Press reports that are being flashed over the country, announcing that "ten of these very honest and reliable aldermen are boodlers and have received $560,000 as bribes in the closets of the City Hall," and that they have adopted the famous Tweed Ring tactics and emigrated. This is a conclusive and practical illustration of the position that I have heretofore taken that municipal lighting should not be owned by a city and controlled by a ring for political or other purposes.

In this paper the author plainly states that electric lights in Chicago cost less than in other cities, because the city owns the plant. It is evident that the author has had no practical experience in electric lighting, and bases his suppositions on theories instead of facts, and it is only charitable to suppose that he has been misinformed, as the figures he quotes regarding the cost of lights in various cities are so utterly at variance with the true condition of the business in those cities. The author claims that the total cost of organization and maintenance of Chicago's electric lighting system is $556,000.

The comptroller of the city, in his financial report, states under oath that the plants cost to January 1st, 1891, $526,184.47; this would leave only $29,815.53 as the expense of running the lights for over four years, according to this author's statement; while the comptroller states that he paid $132,804.48 for expenses of lights for one year. To this must be added the expenses of lights for three years previous to 1891, and we find that the statement regarding the cost made by the author of "Electric Street Lighting in Chicago" is over a quarter of a million dollars less than the actual amount paid by the city.

With over a quarter of a million left out of the account it is very easy to make the cost of lights $68 per year. What are the facts? The pay-roll of the electric lighting department of Chicago, November 7th, 1891, was as follows:

4	Chief Engineers	at	$1,200	$4,800
6	Assistant Engineers	"	1,000	6,000
8	Oilers	"	720	5,760
11	Dynamo Tenders	"	900	9,900
4	Chief Trimmers	"	900	3,600
17	Trimmers	"	720	12,240
16	Firemen	"	720	11,520
4	Day Men (at plant)	"	720	2,880
2	Linemen	"	900	1,800
3	Trouble Men	"	720	2,160
1	Time Keeper	about	1,000	1,000
2	Bookkeepers	"	1,000	2,000
1	Electrician	"	3,000	3,000
2	Assistant Electricians		1,500	3,000
				$69,660

(The above pay-roll does not include the names or pay of thirty employees discharged immediately after the elections of November 3d, none of whom received less than $720 per year.)

The total number of lamps in operation at that date was 963. Therefore, with 963 lamps and a pay-roll of $69,660 per year, we have an outlay of $72.33 per lamp for labor alone, not including anything for coal, oil, waste, interest, repairs, depreciation, water rent, taxes, broken globes and lamps, carbons and other contingencies. Add these, and we find the cost is nearly $190 per year per lamp. With the business in this condition, will the author kindly explain if it was by the system of mathematics taught at the institution he represents that he made the cost of lights only $68 per year?

Notwithstanding the statement that it only costs the city $68 per year to furnish the lights, they have just closed a seven years' contract with one of the local electric light companies to furnish 280 arc lights for street use at $182.50 per year.[1] Would the city pay a private corporation $182.50 per year per lamp if they could produce the light themselves for $68? The author of this paper will find that actual practice and the facts developed by daily business furnish a more reliable basis to work upon than theory and imagination.

The assertion is made that Boston pays $237.25 per year for each lamp, because their lights are furnished by a private corporation. The price paid in Boston is forty cents per night, each lamp burning 365 nights per year, being $146, and $36.50 per year less than Chicago has agreed to pay for the same lights, with coal in Chicago at $1.33 per ton, and in Boston $4.50, and the former city owning a plant of its own. Comment is unnecessary.

The municipal plant at St. Louis was quoted in the hearing before the Massachusetts Legislature as an example, showing that other electric light companies were robbing the public. The St. Louis company have decided to throw up their contract and forfeit their bonds of $50,000 rather than continue the lights at the price called for under the contract. Here is one of the largest and best plants in the United States, favorably located where fuel is cheap, trying to produce street lights for $75 per year. After a year's trial, with the best of management and scientifically handled, they are willing to forfeit $50,000 rather than continue the business at that price.

Do the advocates of municipal ownership imagine that misleading and incorrect statements will benefit their cause or advance their interests? Why not give the facts fairly as they exist and show a true comparison of the two plans, giving all the expenses in each case, and not garble reports? Then the public and taxpayers can judge for themselves which plan is most desirable.

THE SOUTHERN ELECTRIC COMPANY'S SYSTEM OF CONTROLLING LIGHTS.

We have already described in our issues of March 9th and 16th some of the features of the new system for controlling incandescent lights, which has just been brought out by the Southern Electric Company, of Baltimore, Md.

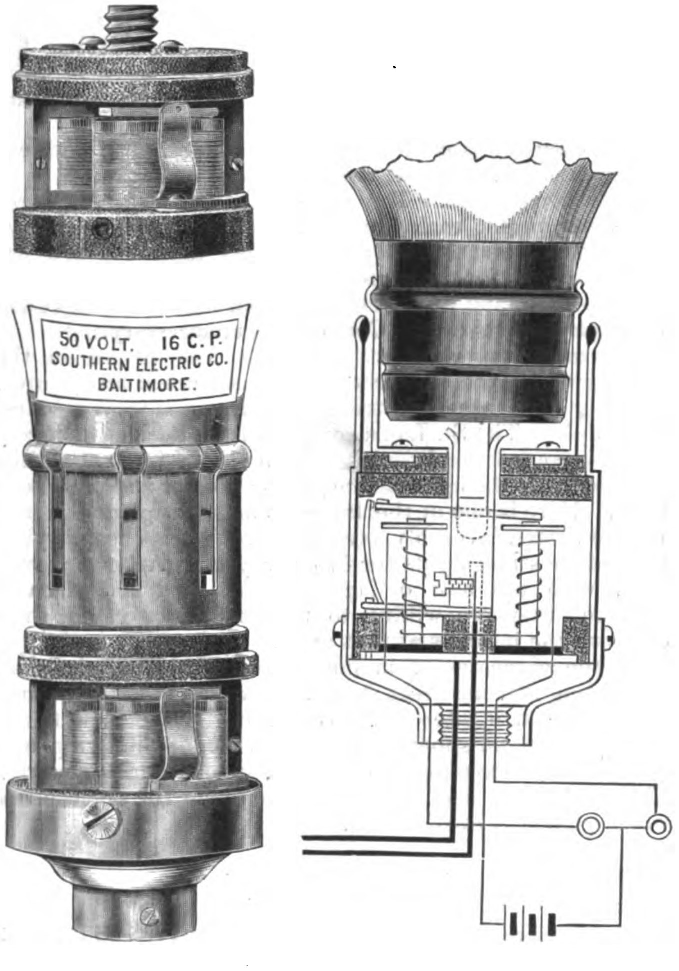
In our March 16th number we showed the "P. & M." push-button switch, and illustrated how, in a very small space, any number of lights may be controlled—turned on or off—by the use of push buttons instead of a switch controlling the current passing through the lamp itself. We illustrate this week a special form of socket, which is perhaps the most important feature of this new system—a socket which is being made for all standard classes of service.

Fig. 1 shows the socket switch itself. This is an electromagnetic key operated by an ordinary battery circuit, controlled by the simple and ingenious push-button switch already described. Fig. 2 shows this switch mounted upon the socket, while Fig. 3 gives an interior view of the combination.

---

[1] Mr. C. H. Wilmerding, general manager of the Chicago Arc Light and Power Co., in a letter to the Editor of The Electrical Engineer, of March 25, says: "In regard to the statement that this company had secured a contract for seven years' city lighting at $182.50 per lamp, would say that although an ordinance to that effect passed the council, it was vetoed by the Mayor."

It will be readily seen that any lamp or any number of separate lamps may be controlled from many different points without changing the lamp circuit itself. If, for instance, in a dwelling it is desired to turn on or off a lamp in any particular room, the push button controlling the special form of socket shown above, may be as many and as far from one another as necessary, the extension of the number simply involving further continuance of the battery circuit which controls the electromagnetic key of the socket.



FIGS. 1, 2 AND 3.—THE P. & M. PUSH BUTTON SWITCH.

Now, if this principle is a good one in the case of a single lamp, why not use it in the shape of a switch controlling a group of lamps in an electrolier? This idea has been carried out in a fixture switch, the operation of which is essentially the same as that of a single lamp.

The system above briefly described is obviously applicable with great economy to the work of theatres, club houses, business houses, residences, and in fact, everywhere; it also possesses advantage in its adaptability to any existing system of incandescent lighting, dispensing with heavy switchboards, snap switches, rheostats, etc.; it has already been introduced in a number of club houses and residences with great success.

The contrast between this system and the old method of operating lights is conspicuous in the case of a well-known installation in Baltimore, where a small board less than 12 x 7 inches, with simple push buttons absolutely controls 140 lights which can be turned on or off by groups or all together, by a light pressure of the finger. It would, therefore, seem that the novelty, economy and pliability of the system generally, cannot fail to interest those actively engaged in electrical construction work and exert a marked effect upon future installations.

DYNAMIC INDUCTION AT HIGH POTENTIALS AND FREQUENCIES.

BY

Elihu Thomson

IT is the purpose of the present writing to supplement the experiments which were described by me a short time since, in which condenser discharges at comparatively high potentials were used to induce by dynamic induction similar discharges in parallel circuits or coils. The application of the principle to the production of an efficient lightning protector or device affording a selective path for high frequency discharges has already been pointed out. So also the effects of the use of varying numbers of turns in the

Fig. 1.

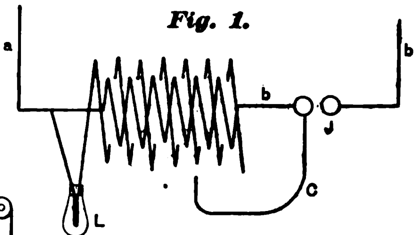


Fig. 2.

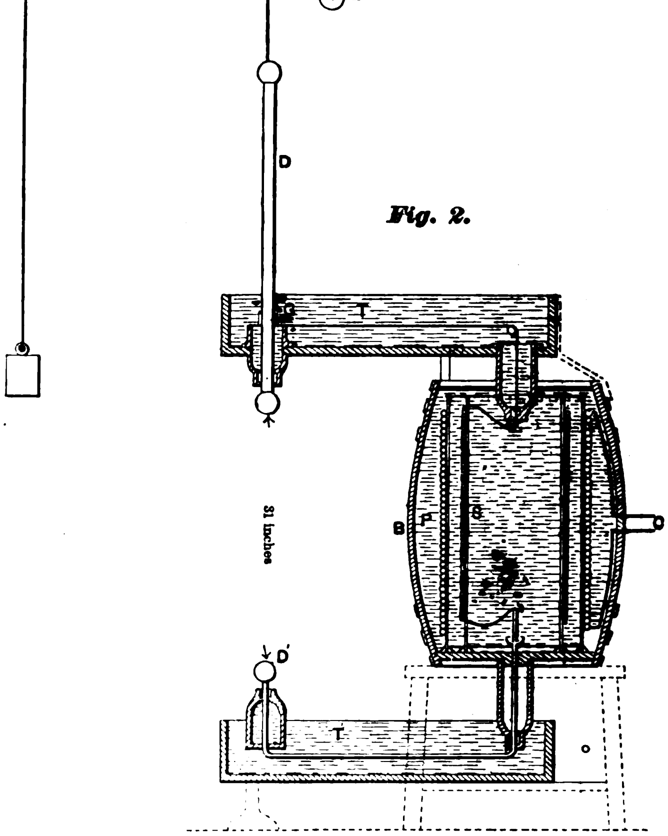

Fig. 3.

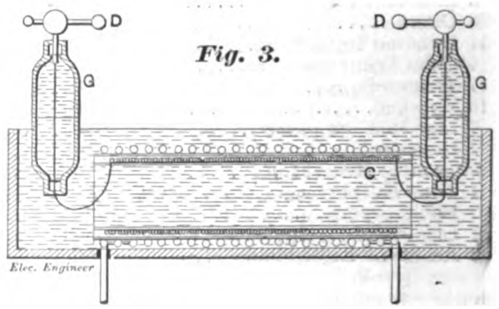

coils under induction have been shown; effects which have enabled me up to the present to obtain sparks of over 31 inches in length in free air between ball terminals about one inch in diameter and in an apparently continuous stream of not less than 250 per second. These sparks are bluish white, like Leyden jar discharges, and are accompanied by a loud rattle or roar. These effects and their bearing on insulation will be further adverted to.

The following experiment is an exceedingly instructive one, as showing the means I use for obtaining a balance of E. M. F.'s or selective path : Two coils of heavy wire are wound, each having about 12 to 15 turns, more or less. The coils are separated by a glass cylinder, one coil being in the interior of the cylinder and the other being wound outside thereof. Connections are made as in Fig. 1. The turns of the coils should be kept apart, or well insulated from one another. An incandescent lamp L is put in circuit with one of the coils, as the outer one, by putting one terminal of the lamp in connection with one end of the inner coil and the other lamp terminal to one end of the outer coil. The wires *a b* permit condenser discharges to be passed through the inner coil; a branch wire C is taken from *b* and its free end can be connected to any part of the outer coil so as to include more or less of the turns of the outer coil in a branch with the lamp around the inner one. With, say, 12 turns in the inner coil, and a possible change of the turns of the outer coil from none to 15 or 16, and passing condenser discharges over an air gap at J with an air blast playing on the spark to prevent continuous arcs, when the condenser charges are furnished by the high potential secondary of an alternating current transformer, the lamp at L would be lighted to a greater or less brilliancy according to the turns of the outer coil in use. In applying the movable wire to the outer coil at a certain point, there is found to be no current passing in the lamp, and on passing this wire either way from this point so as to include more or less of the outer turns, the lamp is lighted with gradually increased brilliancy as the neutral point is more and more departed from. Of course a current indicator, provided it responds to currents of excessive frequency, may be substituted for the lamp. This experiment shows in the clearest manner the fact, that a selective path for the discharges of high potential is obtained in adjusting the relative number of turns in the outer and inner coils.

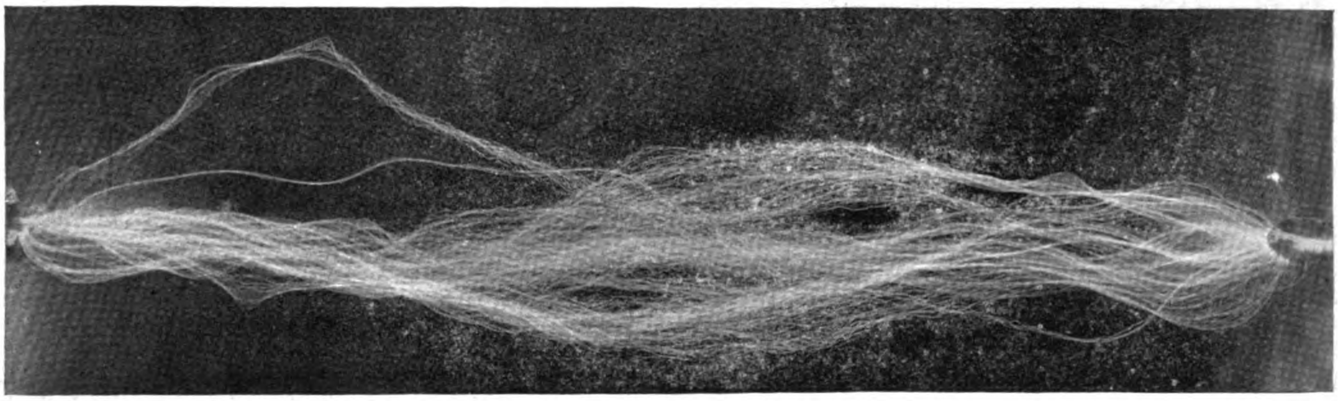

FIG. 4.—DYNAMIC INDUCTION DISCHARGE THROUGH 30 INCHES OF AIR, AT 500,000 VOLTS.

I have in a previous communication stated in what way this combination of inductive coils has been applied as a lightning arrester or protective apparatus for dynamos, motors, transformers, etc. Varying the spark length at J or the condenser capacity does not, so far as has yet been determined, disturb the relations found. It is, of course, necessary that the two coils be well insulated from each other, and this can easily be done by immersion in oil or separating them by glass, hard rubber, or the like.

I will now describe certain forms of apparatus which are adapted for obtaining, at will, very high potential discharges. In fact, I have been able easily to obtain from about 1,600 feet of wire, sparks of over 31 inches between the discharge balls. So far as can be estimated from available data, these sparks are due to potentials of not less than half a million volts.

In Fig. 2, B is a barrel of lubricating oil, an oil of high insulating qualities, being in fact a liquid paraffine. The top of B is open, and in it are immersed the primary and secondary coils P and S, each wound on a paper cylinder. The cylinder on which S is wound is about 3 inches smaller in diameter than the other, and has an external diameter of about 13 inches. It is covered with two layers of silk, and upon this is wound 500 turns of No. 26 cotton-covered wire in one layer with a silk thread between the turns. This layer covers about 20 inches of the length of the cylinder. The terminals of this fine coil are carried out respectively through the lower head and up through the oil above, as will be described.

The primary P consists of fifteen turns of a conductor composed of five rather heavy wires laid alongside, and the connections are made by carrying the terminals outside at O, keeping them about two inches apart. The wire leaving S downward goes to a rod which rests in a cup in the centre of the bottom head of the barrel. This cup has a rod extending down through a glass cylinder filled with oil which dips in a horizontal trough of oil T, through the centre of which is carried a prolongation of this rod to conduct the discharges to the lower discharge terminal D.

The upper end of S is treated in a similar way, passing up through a cork in a glass vessel, such as an inverted bottle with the bottom perforated, then horizontally in the trough T of oil to the sleeve G through which a hollow brass bar D, with rounded ends, may be slid up and down. For this purpose a string and pulley with counter-weight W may be provided. The bar D, should be, say, an inch in diameter to avoid brush discharges from its sides, and in fact, its upper end should be covered with a bottle of oil or have a large polished ball ; otherwise large brush discharges will pass into the air from it. By means of a condenser and spark gap with a blast of air blowing across the gap, the apparatus may be used to obtain the high potential and high frequency sparks. The charging of the condenser is from the secondary of a high potential induction coil given about 15,000 to 20,000 volts, the primary of which coil is fed from alternating current mains. The condenser used in the experiments, consisted of 16 Leyden jars of about a gallon each, which was all there was at command. This will be replaced by a special condenser adapted for such work. The discharges from the apparatus are, as stated, over 31 inches long, and this distance is the maximum that can be given to the space between the terminals as the apparatus is constructed. Fig. 5 shows the actual apparatus.

The power of the discharge is exemplified by the ease with which glass plates are punctured. Heavy pine or even oak boards are perforated and set on fire. The discharges scorch a black line where they pass over a surface of wood, and soften glass where they locate themselves in passing over a sheet. A stick of wood placed between the terminals and joining them, is splintered and torn by the discharge, and is found covered with a fur of fine splinters. Glass vessels are shattered in the line of the discharges, and inflammable matter is set on fire. Perhaps the most beautiful effect is obtained by the insertion of a plate of glass between the electrodes when separated about 24 inches. If the glass be thick enough to resist perforation, the discharges spread all over it and pass around the edges producing an almost indescribably beautiful effect, especially in a feebly lighted room which allows all the minor ramifications of sparks to be seen.

The induction in the fine secondary of the apparatus is about 1,500 to 2,000 volts for each turn which would give 750,000 to 1,000,000 volts total for the 500 turns. But on account of condenser actions absorbing a part of the discharge it is probable that the effective electromotive force between terminals may not much exceed 500,000. We have no ready means of measurement of such pressures. A very simple and inexpensive form of apparatus for obtaining these high potential discharges is shown in Fig. 3. It consists of a wooden trough, the joints of which are capable of holding oil ; its parts may be nailed or screwed together in the ordinary way with shellac or white lead.

The primary coil of ten turns lies against the sides of this trough, and the secondary layer may be an ordinary wire heavily insulated with cotton and wound on a cylinder of paper C or cardboard covered with dry muslin or silk. If the turns are not over six inches in diameter the cotton insulation between turns will suffice, if rather thick, say, $\frac{1}{100}$ of an inch, or over.

The secondary terminals are taken out at the centre of the ends of the cylinder, as shown, and led up through a glass vessel, G, which may be conveniently made of two bottles with the bottoms removed and cemented together ; or a specially blown glass vessel may be used instead. Its object is to hold oil and cover the secondary terminals to a height sufficient to remove them far enough to prevent discharges passing over the surface of the oil in the trough which is used to cover the coils, as indicated. The discharge terminals D D, pass up and outward from the bottles and the sparks are obtained between them. The simplicity of construction is evident, a trough four feet long, will hold a coil capable of giving a spark discharge three feet long. By coupling up two such troughs in tension this effect may doubtless be doubled, if required.

It is important, of course, that all connections, leads from the condenser to the primary coil, etc., be as short and as free from self induction as possible, or the rate of oscillations on which the high inductions depend will be lessened and the effects be weakened to some extent. The potential given by a secondary coil of a certain number of turns depends, of course, on the rapidity of magnetic change and the extent of such change, or maximum densities of field attained. The greater the number of turns in the primary, the greater will be the field strength if the same current flows in every case. But increasing the number of primary turns slows the oscillation rate and diminishes the maximum current value and so diminishes the magnetic density. There is evidently to be selected therefore, for each condenser, that number of turns which will give the highest product of the rate of change and the extent of change or maximum field.

As a striking illustration of the slowing effect of numerous turns of wires on the periodicity or rate of change, it may be mentioned that if, instead of passing the condenser discharges through a coarse coil of few turns, using the spark gap and charging transformer as before, they be passed through a well-insulated coil of many turns of comparatively fine wire, the discharge rate may easily be brought down low enough to cause the spark to whistle along with the sound of the alternating discharges of 125 periodicity used in the charging transformer. The introduction of a well-made iron wire core greatly lowers the tone obtained. It is conceivable that an approximation to music might be obtained from spark discharges sent through coils of such varied inductance as to cause the rates of oscillation to follow those of the musical scale.

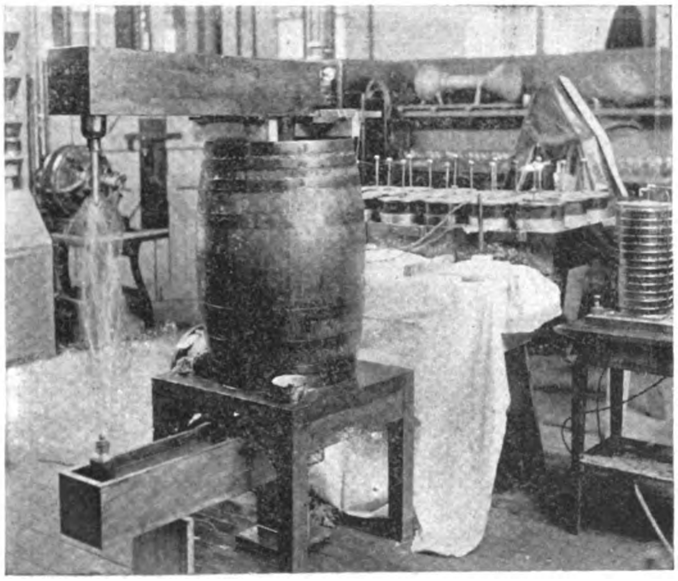

FIG. 5.—APPARATUS FOR HIGH POTENTIAL DISCHARGES.

In the conduct of the experiments on high inductions, which have been described, one cannot fail to be impressed with the capabilities of oil as an insulator. The perforation of two inches of oil between rounded terminals of, say, ½ inch diameter, would seem to demand a potential capable of causing a leap of five feet in air. It appears to be true that edges or points under oil or imbedded in any insulating medium are effective in inducing puncture for the same reasons as they are effective in discharging through air. They act as electric wedges and concentrate the dielectric strains upon those parts of the insulating medium directly in front of such points or edges. Hence, the most perfect insuration to resist puncture in oil or air demands smooth surfaces of as large diameter as possible. This is of course a different matter from insulation resistance or power of resisting leakage.

"IN CHANGE UNCHANGED."

A READER who has every copy of THE ELECTRICAL ENGINEER since April, 1882, writes: "Enclosed please find check for my subscription for the best electrical paper on top of the earth."

BEARING FALSE WITNESS AGAINST ELECTRICITY.

THERE seems to be a growing tendency among insurance companies, or the parties in whose premises disastrous fires have occurred, or the public at large, or possibly our daily newspapers, to make sweeping and, as it were, conclusive assertions, that the damage from fires directly resulted from electric light wires.

Apropos of this we enclose a clipping from the *St. Louis Republic*, relative to a large fire that occurred here yesterday. As stated in the second clipping from the *St. Louis Post Dispatch*, we did the wiring in this building and happen to know that there were no wires within forty feet of the place where the fire started. It is immaterial to us who makes these broadcast statements; they are nevertheless very damaging to our line of business, and to say the least very unjust.

Can't you take this matter up and publish in the columns of your valuable sheet a few lines to serve, as it were, as an antidote for this virulent poison which has been thrown into the public mind? ELECTRICAL SUPPLY CO.,
W. N. MATTHEWS, President.

ST. LOUIS, March 19, 1892.

Personal.

MR. P. J. SHIELS, who has been stenographer for some time past in the office of the *Electrical World* has resigned his position, and will have no further connection with that concern. Mr. Shiels is opening offices in the Bennett Building, corner of Nassau and Ann streets, as a stenographer, typewriter, translator, etc. He is thoroughly familiar with technical work in the electrical field, and is moreover a skilful translator of French and Spanish. Having had opportunities of testing his work, the editors of THE ELECTRICAL ENGINEER can heartily recommend him.

Legal Notes.

PATENTS ON FIBRE RODS.

THE DELAWARE HARD FIBRE CO., Chas. G. Rupert, treasurer, under date of March 12, has issued a special circular, of which the following is a portion:

"We wish to call your attention to U. S. letters patent Nos. 11,173 and 469,238, of which we are sole owners, which cover the mode of making fibre rods as well as the machine for their manufacture.

"We desire to state that we are fully prepared to supply the demand for such fibre rods at reasonable prices, and propose to maintain our rights against infringers. We have accordingly, in pursuance of this policy, to-day brought suit against both the Kartavert Manufacturing Company and the Vulcanized Fibre Company of this city for such infringement, and shall bring such other and further suits as may be necessary to maintain our rights."

THE FINNEY ELECTRIC RAILWAY PATENTS.

THE Pittsburgh *Chronicle Telegraph*, of March 22, had an interesting reference to the Finney patents, owned by the Overhead Conductor Electric Railway Co., in which Westinghouse interests own a majority of the stock. It gives currency to the report that the Thomson-Houston and Edison companies have been desirous to obtain licenses, under royalty, but have not succeeded, and it adds: "The broad character of the Finney invention is shown by the two following claims from one of the patents: 1. The combination, in an electric railway, of a battery or other generator of electricity, an overhead main conductor, a branch conductor connected to a car, and having a traveling contact with the main conductor, an electromotor mounted on the car, and power-transmitting devices connecting the motor shaft to the wheel or axle of the car. 2. In combination with a car motor operated by a leak or branch circuit from a main circuit and regulated by a lever or equivalent device placed on the platform or other accessible part of the car, substantially as and for the purposes described."

STREET CAR MOTORS AT THE CHICAGO ELECTRIC CLUB.

AN interesting discussion was had before the club on March 21, on the subject of singe motors for electric cars, the advocacy of which was undertaken by Mr. E. A. Sperry. Among those who followed him were Mr. W. Le Roy Emmet, who favored the double-motor system, and Messrs. Perry, Sullivan and Arnold.

THE DEPARTMENT OF ELECTRICITY, WORLD'S FAIR.

THE building for "Department J, World's Columbian Exposition," is now rapidly approaching completion and will, when finished, present a strikingly beautiful and harmonious appearance. It is 700 feet long and 345 feet wide, and is appropriately placed in a north and south direction. The general plan, shown in Fig. 1 of the accompanying illustrations, consists of a longitudinal nave 115 feet wide and 114 feet high, crossed by a transept of the same width and height. We have already shown a perspective.

Longitudinal galleries, 115 feet wide, shown in Fig. 2, extend along either side of the building 30 feet above the main floor. These are connected at either end by narrower galleries.

The building will be dedicated on October 12, and exhibits will be received from November 1, 1892, to April 10, 1893, after which date nothing will be admitted. Space not taken possession of on April first will be forfeited.

Exhibitors will not be charged for space, and a limited amount of power will also be furnished gratuitously, while those requiring more can secure it at a fixed price. No single piece of any exhibit of greater weight than 30,000 pounds will be received where machinery is required for its installation. The floor of the building is designed to support 150 pounds to the square foot, and, where exhibits require extra foundations, they are to be built at the expense of the exhibitor.

The designs of all minor details, such as platforms, railings, show cases, partitions, signs, etc., are to be submitted to the Chief of the Department for approval, and will be required to conform to certain rules, artistic and economic, that have been formulated

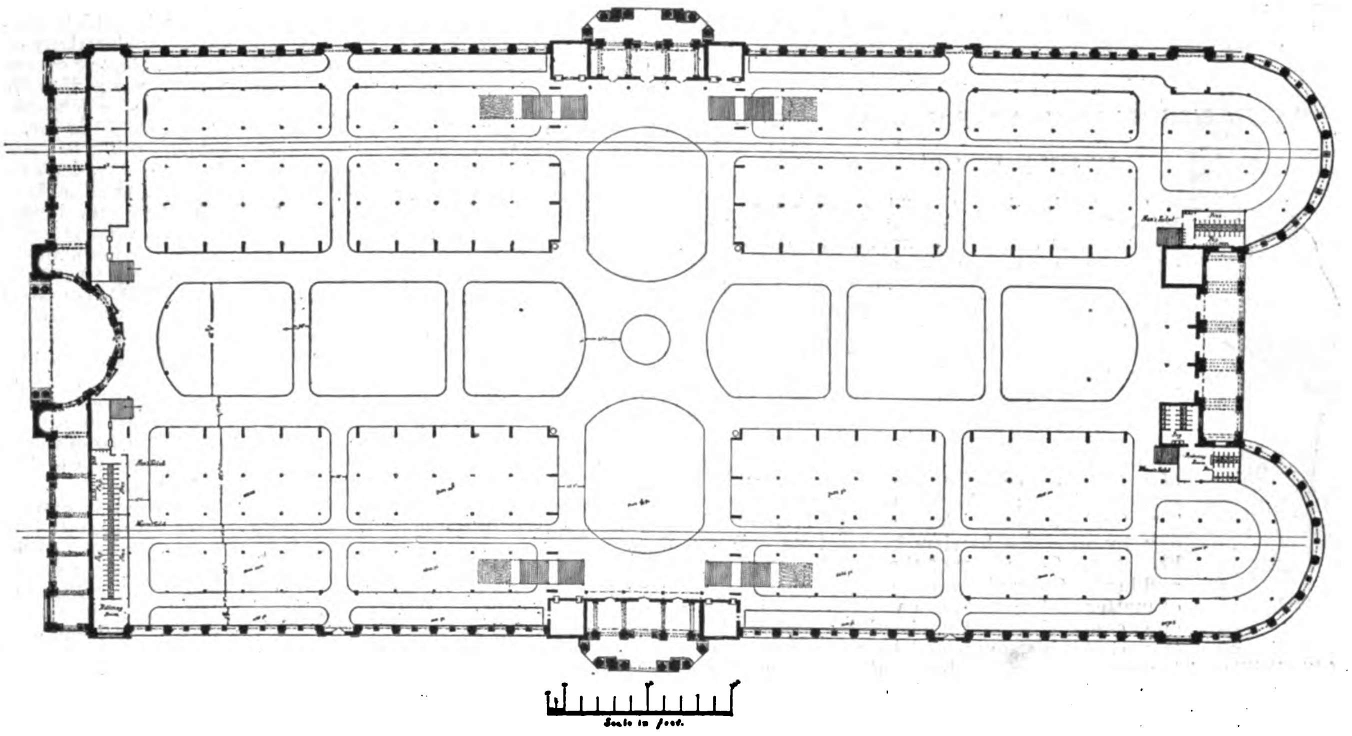

FIG. 1.—GROUND FLOOR, ELECTRICITY BUILDING, WORLD'S FAIR, CHICAGO.

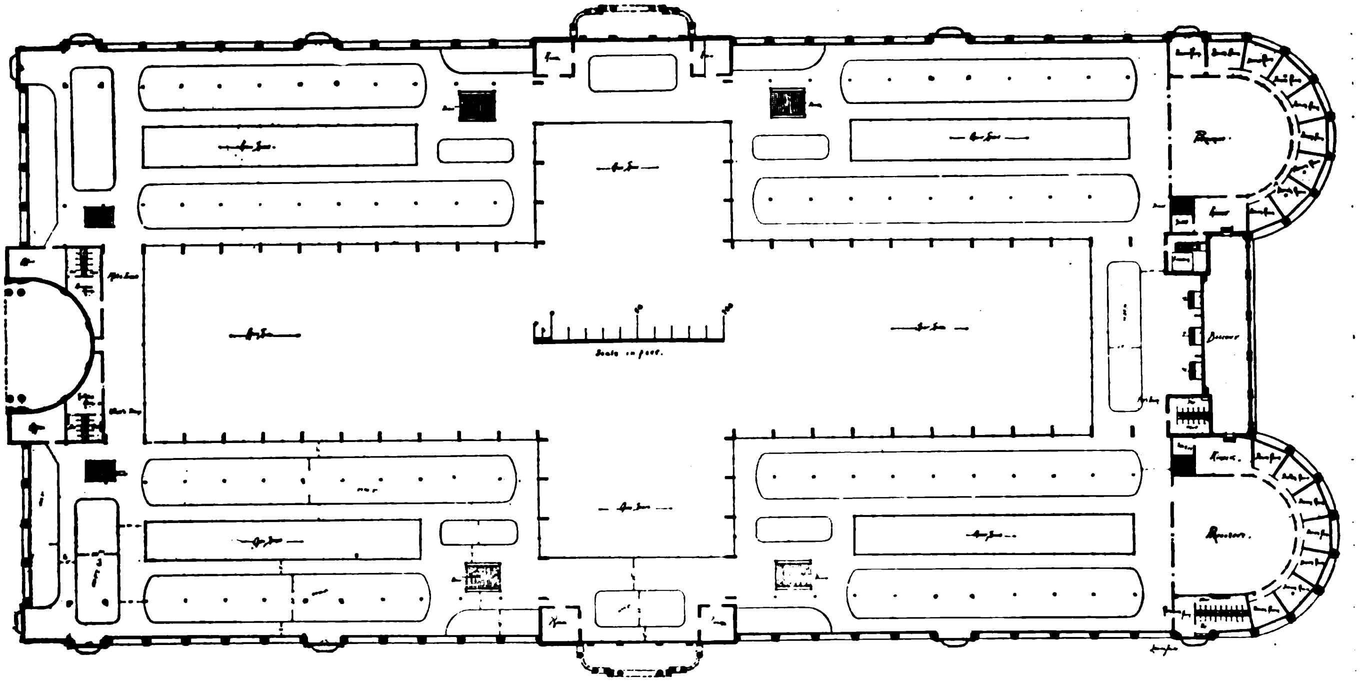

FIG. 2.—GALLERIES, ELECTRICITY BUILDING.

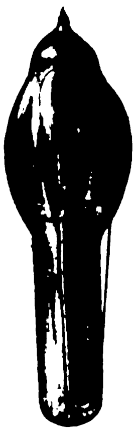
Generators actually operated by steam power will not be exhibited in the Electrical Building, but will be located at the power station, which will also contain the plant which serves the Exposition, while elevators, search lights and other apparatus intended for exhibition but offered for service, may be placed wherever they will be useful, without forfeiting their rights as competitive exhibits.

No duty will be exacted by the Government upon exhibits from foreign countries except in the event of their being sold.

NATURE'S IMMEASURABLE UNUSED FORCE.[1]

BY J. E. H. GORDON.



On Wednesday, the 3d of February, the Royal Institution was crowded with one of the most critical scientific audiences in the world, who were held spellbound for more than two two hours while Mr. Tesla gave an account of his discoveries. Mr. Tesla is a young electrician born at Lika, on the border of Montenegro, and now domiciled in America. The interest of the lecture lay, not in the beautiful experiments with which it was illustrated, nor in the actual facts put forward, but in the hope which it held out that we may now draw back a little further the veil which hides one of the most fascinating mysteries of nature, namely the relations between light and electricity, and between matter and motion. The tendency of modern science is to remove day by day the barriers between its different branches. Our views of the phenomena of light and heat, of electricity and magnetism, and even of matter and motion, are rapidly merging into one general theory of molecular physics, which is perhaps best expressed by the vortex theory of Sir William Thomson. According to this theory the whole of every part of space is filled with a fluid called ether, almost infinitely thin, and almost infinitely elastic. The historic experiments of Faraday interpreted by the mathematical researches of Clerk Maxwell, have demonstrated almost beyond doubt that the same ether whose waves carry light and heat from the sun and stars to the earth, also carries the waves of electric and magnetic induction which follow each outburst of solar activity.

Sir William Thomson holds that all that which we know as matter consists of vortices or whirlpools of this ether, which, from their rapid rotating motion, resist displacement, and therefore show the common properties of hardness and strength in the same way as a spinning top or gyroscope tends to keep its axis in a fixed direction. But whether the molecules or particles of what we know as matter are independent matter, or whether they are ether whirlpools, we know that they keep up an incessent hammering one on another, and thus on everything in space.

Prof. Crookes has shown that the forces contained in this bombardment are immensely greater than any forces we have yet handled, many millions of horse power being contained in an ordinary room. Owing, however, to the forces being in every possible direction they neutralize each other, and no result of them is perceivable to our senses: but if ever we discover how to so direct their courses as to send the majority of them in the same direction, we shall have at our disposal forces as much exceeding any we are now acquainted with as the blow struck by a bullet exceeds the force required to pull the trigger of a gun. In fact, as Mr. Tesla put it in his lecture, "We shall then hook our machinery on to the machinery of Nature." It is because they hold out to us a hope, however distant, of some day so guiding the ether storm, that the experiments of Nikola Tesla are of such transcendent interest and importance.

Prof. Crookes, in his experiments on "radiant matter," has given us the first hint of a method of directing what, for want of more exact acknowledge, we will call the molecules of matter. With the appliances at his command, however, he was unable to impart any great change of direction, but he succeeded in making that change manifest by reducing the disturbing forces acting against his directing force. In other words, he pumped out from glass bulbs and tubes nearly all the air or other gas that they contained, and the comparatively few particles left were then free to travel in any course imparted to them without much change caused by collision with others. This special direction was imparted by means of electricity, and gave us the beautiful phenomena of phosphorescence and radiant matter which are now so well known in these experiments.

By means of suitably shaped terminals a stream of molecules is focused on a given point. If a piece of carbon or platinum is placed at that point it becomes white hot under the bombardment from identically the same cause which induces a sheet of flame to appear when a cannon shot strikes an iron target. If a ruby or other phosphorescent material is placed there it glows with its characteristic color, and if a little delicately balanced vane or windmill is placed so that the stream is directed on one side of its fans, it rapidly revolves. The forces available in these experiments were, however, almost indefinitely small, being, as it were, merely flying spray from the great torrent into which we have not yet been able to penetrate.

Now for the advances made by Tesla.

In all the above experiments the electricity by which the directing force was imparted to the molecules was electricity of a comparatively slow alternation period, namely, electric currents oscillating about 80 to 100 times per second. It was as if we had tried to ventilate a room by causing a man to walk slowly through it with an umbrella. He would undoubtedly move the air, but would move it so slowly that ordinary methods would be insufficient to enable us to perceive its motion. In order to cause a rush of air we must put up a rapidly moving fan or other suitable machinery. Mr. Tesla, seeing this, abandoned the ordinary dynamo, which, as we have already noted, gives about 80 alternations per second, and the ordinary induction coil, which gives about the same number, and constructed a dynamo which gives 20,000 alternations per second, and by connecting this to suitable condensers he multiplied its alternations until they reached 1,000,000 or 1,500,000 per second.

Then at once an entire set of new phenomena appeared, and the experimenter entered a region of mystery and hope. One of the first things noticed was that, either because these vibrations are too rapid to excite corresponding vibrations in the nerves of the body, or from some other cause, no shock is felt from the current; and that though an ordinary current at 2,000 volts will kill, yet this current at 250,000 volts cannot be felt at all.

It was also found that the vibrations keep time in some unknown way with the vibrations of solid matter. Vulcanite is one of the best insulators known, and will entirely stop any ordinary current or discharge, but the stream of sparks between two poles with this current pours through a thick sheet of vulcanite as easily or even with greater ease than through air. It does not perforate it in any way, but passes through it as light passes through glass.

All the "Crookes" phenomena of radiant matter are almost indefinitely increased; it is the blow of mitrailleuse bullets compared to the blow of an air ball thrown against the wind. The forces can be directed for a considerable distance through space without the aid of wires. Electric lamps light easily when attached to one single wire and require no return conductor; and, more wonderful still, if metal plates are fixed on the roof and walls of a room and connected to the terminals, the whole atmosphere of that room, whether it be ether or whether it be particles of common matter, is thrown into a state of storm and agitation which can be be at once made perceptible by bringing into the space tubes or globes from which the air has been partially exhausted. Such tubes, though without any metallic connections, yet glow and throb as if powerful currents of electricity were being sent through them from an ordinary induction coil. A Crookes radiometer placed near a metal conductor from which neither spark nor glow is perceptible, yet rotates as if it were placed near a lamp or heated body, but rotates in the wrong direction, and a true flame burns in which nothing is consumed.

When the discharge issues from a suitable terminal it has the appearance and roaring sound of a gas flame burning under too high a pressure, and gives off a considerable heat; to use Mr. Tesla's words again: "This is not unexpected, as all the force and heat in the universe is due to the falling together of lifted weights, and the same result is produced whether these weights have been lifted apart by chemical energy, and rest in the form of oxygen and hydrogen ready to combine chemically, or in the form of energy or moving molecules directed by the electric current."

Should the application of Mr. Tesla's results ever fulfil the bold dreams of scientific imagination, we shall see a social and political change at least as important as that caused by the railway system or the electric telegraph. Most manual labor will become unnecessary, as unlimited power will be available at every man's hand. Engineering works will be able to be carried out on a far greater scale than has yet been even contemplated, and doubtless a corresponding era of material prosperity will set in; but, whether these dreams are ever fulfilled or not, few who attended Mr. Tesla's lecture will forget the possibilities which seemed to open to their minds when they saw a living man standing in the midst of the electric storm, receiving unharmed in his hands flashes of veritable lightning, and waving above his head a tube, through which the very life blood of creation pulsed, in waves of purple fire.

A NEW STATION FOR WILLIMANTIC, CONN.

It is expected that the new station of the Citizen's Gas and Electric Co. will be in operation in a few days. The building is of brick, two stories high, and was begun last November when the above company bought the interest of the Willimantic Electric Light Co. The new officers are E. S. Bois, president; Julius Pinney, secretary; O. H. K. Risley, treasurer.

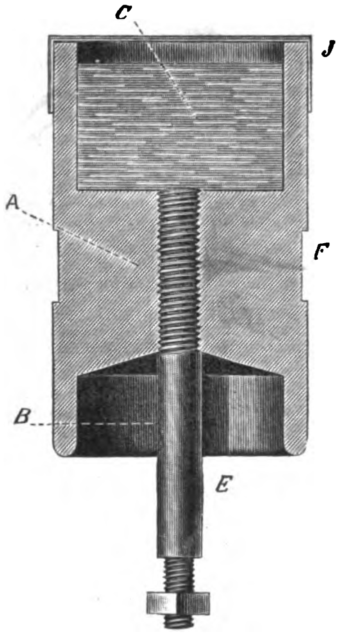
THE HEWETT POROUS OIL INSULATOR.

BY

RJ Hewett

Believing that the problem of a successful open conduit trolley system for street car propulsion depends in a measure upon efficient insulation of the naked conductor, the writer has worked out this invention with a view of filling such requirements. In looking at the conditions which exist in an open conduit, we see that the humidity of the atmosphere will always be greater than in the open air above ground. Aside from this, in dry weather a certain quantity of dust will find its way into the conduit and adhere to the insulators. From this the writer was led to the conclusion that an insulator to be used under such adverse conditions should be designed so as to obviate these difficulties as much as possible.

In an article on oil insulators for high tension currents, by F. L. Pope, which appeared in The Electrical Engineer of October 25, 1891, there was given a brief description of an oil insulator invented and patented by the writer. The process of development has produced forms of insulators much superior to the original ones, among them being the improved form shown in section in the accompanying engraving.



The Hewett Porous Oil Insulator.

The body of the insulator A is composed of wood, and has the usual bell shape at the bottom. The upper part of the insulator is formed into a cup C, which is filled with insulating oil, which saturates the entire porous body of the insulator and passes out in the bell B, the crown of which is beveled, as shown. The beveled shape of the crown causes the oil to run outward to the rim, down which it flows in a thin film to the edge, where it drips off. The bell of the insulator is thus supplied with a constantly renewed surface of oil, which carries away any particles of dirt that may lodge upon it, and thus prevents the formation of a continuous film of moisture even in the most humid condition of the atmosphere. A cap J covering the oil cup can be removed when necessary to refill the cup with oil. A groove F is provided for receiving a clasp, by means of which the insulator is attached to the conduit or manhole. To the end of the shank E is attached the wireholder.

Experimental work has shown that wood is more suitable than porous earthenware. Aside from being cheaper and less liable to breakage, it is more suitable on account of its peculiar porous structure, it being quite porous in the direction of its fibrous structure, but only slightly porous in a transverse direction. This peculiar porous property of wood causes the oil to pass out of the body of the insulator more freely at the place where it is most needed, that is, in the bell.

Woods of a rather close grain, such as wild cherry and soft maple, are most suitable. The wood is split and cut into billets of suitable size, and treated by a special process which drives out all moisture, resin and other volatile matter, and thoroughly shrinks it so that no further shrinkage can take place. After this the billets are turned down to the proper shape and the shank put in place. This special treatment obviously improves the insulating qualities of the insulator.

The insulator is applicable to other cases of a similar nature, such as tunnels and mines worked by electric mining locomotives and other cases where naked wires are to be insulated under adverse conditions of atmospheric humidity.

Letters to the Editor.

ECONOMY IN ARC LIGHT WIRING.

The interesting paper under the above caption by Mr. Sharpsteen in your issue of March 16, suggests to us the propriety of referring to the method by which this company accomplishes the same object, viz.: the simplification of circuits and consequent saving of initial capital as well as subsequent maintenance.

We have endeavored to approach this subject in the spirit of engineers, not of mere salesmen. The operating electric light companies both in the larger cities and smaller towns seemed to us to be between the horns of a dilemma; either they had to run separate circuits for each class of lights or else burn the short-term lights until those of the longest term were cut out. Both methods were wasteful, and it was only a question as to which would cost the more in the long run.

To meet the contingency we applied our principle of "Individual Selection" and worked out a system of "Individual Cut-Outs" by means of which any loop of lights or motors on a given circuit could be cut out or in at any time from the central station without affecting others on the same lines. Adapting this plan to the case cited by Mr. Sharpsteen, we would dispense with the third wire of a larger capacity and run a No. 12 wire on which the locks and cut-outs would be placed. The commercial and city lamps would be put on the same circuit; the former grouped into convenient classes, say 9 o'clock, 10 o'clock and midnight or any other arrangement called for by contract requirements. One of our combined locks and cut-outs would be placed in each loop, and each set of lights cut out at its contract hour by the central station operator using the transmitter provided for that purpose. This would leave the city lights burning alone when the last commercial lamps were extinguished and allow the commercial lights to be started an hour or two earlier than the city lamps, as is necessary in most cases, and thus effect a saving of current. In the same manner, each loop would be cut in again when its hour arrived. If it should happen that the lights of one class were so separated that they could not be advantageously brought into one group, they could be divided into sub-loops and a switch (as distinguished from the combined lock and cut-out) be introduced in each one. In this case the one lock would work all the switches on its own loop together. The extra expense would be confined to a slightly greater length of No. 12 wire, which is the size used in connecting up our locks and switches, all of which are operated with a single line.

If a comparison be made between this system and the method of wiring usually adopted, ours will be found to possess some very positive advantages both on the score of economy and otherwise. Those who have been forced, by unsympathetic municipal authorities, to go underground with their wires, will find that they can save many a mile of costly feeders, while those to whom the air is yet free are enabled to run a single feeder to distant points of distribution and there divide their circuit into loops controlled at pleasure from the central station. Many modifications of this use are feasible, for our object has been to furnish a system elastic enough to be of general utility. The vital feature is that the power of selection is placed with the central station and its control of individual lamps, motors or groups made absolute, irrespective of distance or variety of class.

Our conviction that we are giving electrical engineers as well as light and power companies an effective means of simplifying and consolidating their services is our excuse for encroaching upon your space, and at the same time showing as marked an advance over the plan sugested by Mr. Sharpsteen as is his over the well-known metallic system for the control of each bank of lights.

Electric Secret Service Company,
By C. P. Mackie, Gen. Manager.

New York City.

THE TWO DROMIOS.

Having learned of another of the samena me engaged in electrical work, I beg to state that hereafter I shall sign myself as below.

If you will kindly publish the above, you will confer upon us both a great favor.

H. Robinson Wellman.

94 Hough Avenue,
Cleveland, O., March 22, 1892.

A U. S. ELECTRICAL EXPERIMENT STATION FOR AGRICULTURE.

I forward to your address a copy of the bill to establish an electrical experiment station. Our Kansas people have been experimenting a good deal in this line, and have come to the conclusion that, with a little help on the part of the Government, great things will result in the direction of the use of electricity as a propelling power as applied to farm implements and machinery. Personally, I have long been of opinion that this can be done. We are now using storage batteries in the propulsion of railway cars and of various other classes of machinery. I can see no good reason why we cannot do the same thing as to farm machinery, and in that way much cheapen production.

W. A. PEFFER,
U. S. Senator.

WASHINGTON, UNITED STATES SENATE, March 22, 1892.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 15, 1892.

Accumulators :—

Secondary Battery, G. F. Parker & C. E. Crapo, 470,701. Filed April 10, 1891.

Employs a dome-shaped metallic plate provided with tapering recesses for the active material extending through the plate and arranged in the exciting liquid in a horizontal position, the concave side of the plate being downward for the retention of the gases.

Alarms and Signals :—

Police and Fire-Alarm Signaling Apparatus, L. B. Firman, 470,666. Filed April 1, 1889.

A multiple signal box designed to send emergency signals and also the customary police signals.

Combined Police and Fire-Alarm Signal Apparatus, L. B. Firman, 470,667. Filed Nov. 28, 1890.

A combined fire-alarm and police circuit system.

Tell-Tale Device for Electric Circuits, E. Tregoning, 470,722. Filed Oct. 2, 1891.

Consists of a solenoid having a movable tubular core provided with means for closing an annunciator circuit.

Electrical Hose-Signaling Apparatus, W. Fowler, 470,752. Filed Aug. 24, 1891.

Provides means whereby signals may be instantly passed back and forth between the men at the fire engine and those at the nozzle of the hose.

Appointment Signal for Telephone, S. W. Gray, 470,786. Filed May 12, 1891.

An arrangement by which, in the absence of the person called, the time of his return may be indicated by means of a signal in the receiver at the transmitting station without the use of an additional bell, but merely by placing the signal mechanism in circuit with said receiver and a source of electricity.

Switch for Electric Sigaling Apparatus, L. Sellner, 470,798. Filed Oct. 17, 1891.

A switch for signaling apparatus in which the signals are produced by means of multi-colored incandescent lamps, intermittingly brought to incandescence.

Electric Railway-Signal, A. J. Wilson, 470,813. Filed Nov. 9, 1991.

An automatic block signal for railways.

Time Indicator and Alarm, H. Bennett, 470,816. Filed Sept. 1, 1891.

Annunciator, A. H. Brintnell, 470,831. Filed April 11, 1891.

A thermostat which, in addition to a fire-alarm, will also act as an alarm of warning in case of incipient heat.

Employee's Time-Recorder, W. Lucas and T. A. Garrett, 470,810. Filed April 21, 1891.

Conductors, Conduits and Insulators :—

Insulation for Electric Wires, S. Vanstone, 470,883. Filed Mar. 21, 1890.

An insulation consisting of abutting longitudinally divided sections of rigid non-conducting material, the abutting ends forming a socket joint.

Electric Conductor, T. A. Edison, 470,924. Filed Sept. 30. 1887.

Has for its main feature the use of an insulating covering, consisting of a mixture of rubber with an infusible material in the form of a powder.

Underground Electric Conduit, J. F. Munsie, 470,896. Filed Oct. 9, 1889.

Distribution:—

Transmission of Electrical Energy to a Distance, M. Deprez and J. Carpentier, 470,865. Filed Nov. 27, 1888.

Claim 1 follows:

The improvement in the art of transmitting electrical energy to, and utilizing it at a distance from the source, which consists in generating maintained and practically uniform currents of high tension at one station, and sending the same over a line of conductors to another station, and generating maintained and practically uniform currents of lower tension at the second station by the inductive influence of the high tension currents.

Dynamos and Motors:—

Field Magnet for Dynamos, G. E. Dorman, 470,749. Filed Dec. 17, 1890.

Consists of a series of short over-lapping arc-shaped segments with inwardly projecting ends in alignment so as to form a circular field magnet with inwardly projecting pole-pieces.

Dynamo, W. H. Elkins, 470,784. Filed June 29, 1891.

A dynamo in which the current taken from the armature is divided, one portion going through some of the field coils and the rest through other field coils before the two divisions unite to form the current through the work circuit.

Dynamo, W. H. Elkins, 470,785. Filed July 11, 1891.

Similar to No. 470,784.

Electric Railway Motor, F. O. Blackwell, 470,817. Filed Aug. 31, 1889.

A motor journaled directly upon the axles of the vehicles between the wheels, gearing without the intervention of the countershaft and having sufficient torque to propel the vehicle under all circumstances.

Dynamo-Electric Machine or Motor, T. A. Edison, 470,926. Filed Feb. 24, 1891.

Employs a magnet pole-piece consisting of several distinct layers of iron or steel united for a part of their length in an integral mass.

Alternating Current Generator, T. A. Edison, 470,928. Filed Aug. 25, 1891.

Claim 3 follows:

In an electromagnetic machine a circular field magnet built up of overlapping plates, said plates having bodies and projecting legs which constitute the pole-pieces of the field magnet, and being in contact with each other for a portion only of their length.

Dynamo-Electric Machine, T. A. Edison, 470,930. Filed Oct. 10, 1891.

Employs an armature coil covering the entire surface of the core, a commutator having a number of conducting blocks, a series of field magnets forming a succession of alternating like and unlike fields, commutator connections between all portions of the armature coils situated in corresponding magnetic fields and the same commutator blocks, whereby a continuous current is produced, the commutator brushes taking current from and delivering current to all parts of said coil.

Galvanic and Thermo-Electric Batteries :

Galvanic Battery, F. H. Root, 470,792. Filed Nov. 5, 1888.

Comprises a cell closed at its top and provided with a vent tube, a packing of mineral fibre arranged within the cell, a chloride of silver electrode embedded within the packing, a zinc electrode surrounding the packing, and an excitant consisting of a caustic solution.

Lamps and Appurtenances :

Arc Light Hanger, C. A. Pfluger, 470,766. Filed May 15, 1891.

Manufacture of Filaments for Incandescent Lamps, T. A. Edison, 470,922. Filed Oct. 10, 1883.

Method of forming blanks for filaments consisting in treating separately two or more sheets of paper with hydrofluoric acid to form a cementing material and then placing the sheets together.

Manufacture of Filaments for Incandescent Electric Lamps, T. A. Edison, 470,925. Filed Mar. 20, 1880.

Claim 1 follows:

A filament for forming the carbon incandescing conductor of an electric lamp, consisting of a number of fine filaments welded together by a carbonizible cementing substance.

Miscellaneous :—

Electric Connector, W. H. Garland, 470,820. Filed Nov. 23, 1891.

A binding strip consisting of a short section of wire having two terminal sleeves adapted to slip over the ends of such strip and be inserted in holes at the ends of the rails.

Magnetic Separator, T. A. Edison, 470,929. Filed Oct. 1, 1891.

Appliance for Sighting Guns, L. M. von Markhof, 470,942. Filed Nov. 6, 1890.

A ship's gun, to which is connected a normally interrupted electric firing or alarm circuit.

Electric Elevator, R. C. Smith, 471,063. Filed Nov. 11, 1891.

Relates to means for operating an electric elevator at different speeds.

Electric Elevator, R. C. Smith, 471,064. Filed Nov. 30, 1891.

Similar to No. 471,063.

Railways and Appliances :—

Electric Railway, E. M. Bentley, 470,654. Filed Dec. 11, 1885.

Claim 1 follows:

The combination with two electric railways having separate sources of current, of a section of conductor common to both of said railways, but insulated from the main conductors of one road.

Motor for Electric Cars, F. O. Blackwell, 470,656. Filed Dec. 4, 1890.

Claim 2 follows:

The combination of an electric motor geared to the axle of a truck and having flat field magnets, recessed transversely with coil windings surrounding the armature disposed in such recesses and removable therefrom.

Contact Device for Electric Railways, F. O. Blackwell, 470,657. Filed Jan. 26, 1891.

Consists of a supply conductor inclosed in a slotted conduit and a contact device comprising a shank extending through the slot and a pivoted spring actuated contact maker furnishing means for supporting the contact device on the conductor.

Railroad Circuit-Closer, F. E. Kinsman, 470,806. Filed July 30, 1891.

Has for its object a device which shall not be subject to interference from the presence of frogs, crossings or switches on the line of rails over which the vehicle travels.

Railway Time-Signal, H. Gosman, 470,821. Filed May 23, 1891.

Electric Wire-Support, F. O. Blackwell, 470,844. Filed June 17, 1889.

Consists of a trolley wire hanger of malleable material having a groove at one side to contain the line wire and projecting pieces that clamp over the wire holding it firmply to the supporter.

Railway-Signaling, T. A. Edison, 470,923. Filed Aug. 19, 1887.

Relates to the operation of electrically controlled signals upon railway lines and has for its object the elimination of the making and breaking contacts for this purpose.

Driving Mechanism for Cars, T. A. Edison, 470,927. Filed Mar. 26, 1891.

Driving mechanism for electric cars consisting of the use of sprocket wheels and link belts.

Switches and Cut-Outs :—

Protector for Electrical Apparatus, C. H. Morse, 470,697. Filed Jan. 12, 1892.

Consists of two independent helices on opposite sides of the circuit including the apparatus to be protected, an armature extending across the cores of said helices, two contacts respectively connected to the opposite sides of said circuit, and one contact connected to the earth, together with a short circuiting and grounding weight normally locked to said armature.

Lightning Arrester, E. Thomson, 470,721. Filed Dec. 26, 1889.

Claim 5 follows:

The combination with the arcing electrodes and arc-rupturing magnet of a surrounding cage or barrier arranged around the electrodes and provided with a number of discharge openings.

Lightning Arrester, G. M. Bacon, 470,736. Filed Aug. 10, 1891.

Employs a series of carbon points so arranged as to be automatically thrown in and out of circuit of the discharge.

Electric Switch, S. Deacon, 470,748. Filed Mar. 18, 1889.

Has for its object to secure a quick movement of the parts in changing from one position to the other.

Circuit-Interrupting Device, A. Wurts, 470,772. Filed Nov. 25, 1891.

Claim 4 follows:

The combination of two cylinders of brass normally resting in contact with each other, yielding thermostatic supports for the respective cylinders and circuit connections through said supports with said electrodes.

Circuit-Interrupting Device, A. Wurts, 470,773. Filed Dec. 1, 1891.

Claim 1 follows:

An arc-interrupting device consisting of two or more electrodes of zinc, antimony, or compounds thereof, or other materials having a non-condensing, vaporous oxide.

Apparatus for Protecting Circuits, A. Wurts, 470,774. Filed Dec. 16, 1891.

Employs in connection with the dynamo circuit a static discharge circuit and a circuit controller alternately connecting the poles of the dynamo with the discharge circuit.

Electric Switch, H. Moore and O. O. Jarrard, 470,790. Filed Sept. 4, 1891.

A quick-breaking switch simple in its construction and efficient and durable in use.

Contact Maker, D. Draper, 470,994. Filed Sept. 30, 1891.

A positive contact maker for use in clocks, meteorological instruments, etc.

Telegraphs :—

Printing-Telegraph, E. J. Silkman, 470,768. Filed Apr. 16, 1891.

A page-printing telegraph in which two duplicate electrically actuated typewriting machines are so arranged that the transmitting operation can simultaneously duplicate the message at his own and at the receiving station by means of a single connecting line wire.

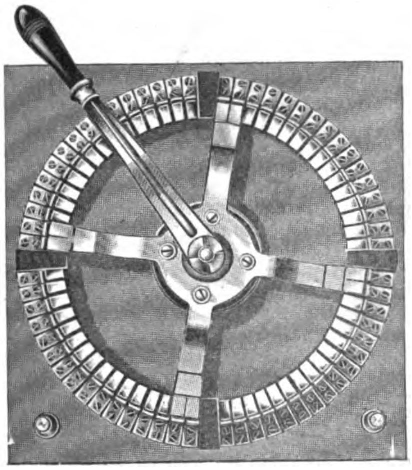
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Persistant advertising makes a permanent business.

THE EDISON STAGE REGULATING SWITCH.

THE EDISON GENERAL ELECTRIC COMPANY has brought out a new stage regulator switch shown in the accompanying illustration, by means of which gradations of light are obtained delicate enough to satisfy even the most fastidious of stage managers. This switch mounted on a slate base, consists of fifty clips arranged in a circle in four divided quadrants with a four-armed contact passing over them, and engaging in a clip every quarter width of the clip. Contact over the entire fifty clips is made by a movement of the switch handle through an angle of 45 degrees only, instead of through 120 degrees, as in all other stage regulators yet devised, and thus the speed of the operation is considerably increased. These switches are either directly mounted on the sides or the top of the fireproof stage regulators, or are mounted separately upon a switchboard and connected with the regulators by means of regular fireproof cables made up of the strands of the connecting wires. They can also be arranged in a special frame in such a manner that the handles can be worked separately, or, connected together, be all operated as one unit.



THE EDISON STAGE REGULATING SWITCH.

THE ILLINOIS ELECTRIC LAMP COMPANY.

THIS company has been organized under the laws of the State of Illinois, with a capital stock of $25,000, all paid up. Chas. M. Howell is president, C. J. Laughren is secretary and treasurer, and J. F. Schaefer superintendent, the original manufacturer of the Jewel incandescent lamp, which has acquired an enviable reputation with the public, and a man who is one of the oldest lamp makers in the country and has done considerable in improvements on lamps as well as on apparatus to manufacture lamps. Attention is called to the announcement in our advertising pages this week. The company's factory is now in operation, located in the business centre of Chicago with a capacity of about 1,000 lamps per day. They furnish lamps of any candlepower and voltage and to fit all sockets. Three Kester dynamos generate the necessary current of different potentials for the production of the filaments and the testing of all lamps. Three large-size Clayton air compressors are used to act as mechanical vacuum pumps, and 40 Schaefer automatic mercury pumps are used to exhaust the lamps,

THE "UTICA" BELL.

A NOVEL bell is that which the Utica Fire Alarm Telegraph Co. are just introducing. It is reliable and efficient and is made to sell at a reasonable price. Unlike most inexpensive bells this one is firmly secured to an iron back and is provided with a metal cover nicely nickle-plated or ornamented as desired. An entirely new feature in these bells is that the position of the magnet is such that both poles have equal power, thus requiring less battery. This company also manufacture a most desirable annunciator and guest return call system. The Plaza Hotel, New York, is equipped throughout with this system, which is giving excellent satisfaction.

LIGHTING AT DANBURY, CONN.

THE DANBURY AND BETHEL GAS AND ELECTRIC LIGHT CO. are about to remove to their new brick station. It is a feature of interest that all their steam engines will be replaced by three Otto gas engines of 100 H. P. each, consuming "producer gas" as fuel.

The local public are said much to prefer arc lights hung low on mast-arms, to clusters on iron towers.

Mr. Charles H. Merrit is president; Mr. H. Williams, treasurer, and Mr. G. E. Cowperthwait, secretary and superintendent of the company.

A DECISION IN FAVOR OF THE CONSOLIDATED ELECTRIC STORAGE CO.

JUDGE GREEN, of the United States Court for the District of New Jersey, last week handed down a decision in the case of the Consolidated Electric Storage Co. against the Accumulator Company, in which he found for the complainants and ordered that an injunction issue against the defendant. The injunction was issued March 19.

It will be remembered that the complainants above obtained a perpetual injunction last December against the Electrical Accumulator Company of New York. This company, however, has ceased to exist any longer, and was succeeded nearly two years ago by the Accumulator Company which is incorporated in New Jersey. The complainants above were therefore compelled to go before the United States Circuit Court in New Jersey in order to obtain an injunction against the Accumulator Company. The argument was had before Judge Green on the 7th of January last. This is the fourth decision sustaining the patents of the Consolidated Electric Storage Company, to wit, the Brush patents.

H. W. JOHNS MANUFACTURING CO.

THE consolidation of the Gould & Watson Co., of Boston, with the Johns-Pratt Co., of Hartford, was consummated on the 22d inst. The mica insulation made by the Gould & Watson Co. will now be manufactured at the Hartford factory of the Johns-Pratt Co. This company will hereafter make the "Vulcabeston," "Monarch" and "Mica" insulations. The H. W. Johns Manufacturing Co., of New York, Boston, Chicago, Philadelphia and Atlanta, will continue as selling agents.

CENTRAL ELECTRIC CO.

SINCE the Central Electric Company took the agency for the Interior Conduit & Insulation Company, they have been overwhelmed with orders, the largest buildings in Chicago, St. Louis and Kansas City being equipped and now in course of construction. The business in this department of the Central Electric Company bids fair to be one of their prominent features.

The Central Electric Company report activity in their pin and bracket department, their factory at Columbia City being in full operation, and the goods being sent far and near in carload lots. The pin and bracket made by this firm is of approved quality, and has a steady demand.

PATENTS ON BATTERY CARBONS.

THE NEW YORK CARBON WORKS, of 18 Cortlandt street, have recently issued the following notice:

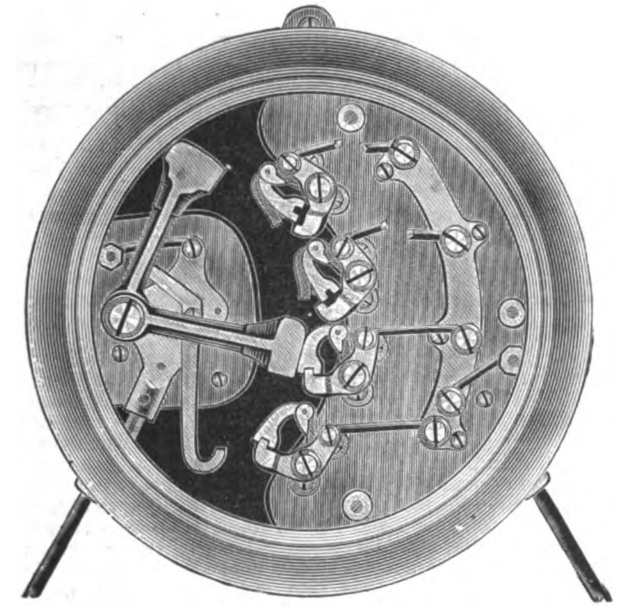
"For the protection of manufacturers, dealers and users of carbon cylinder batteries, we beg to notify all interested, that we have secured from Mr. Chas. W. Holtzer, the sole and exclusive right to manufacture carbon cylinders or cups, under his patent, No. 327,878, dated October 6, 1885; all cylinders will bear date of patent, also our trade mark, thereby protecting all users of same from infringement."

With regard to the above, the Fitch Battery & Electric Co., of Oneida, N. Y., have issued the following:

"Referring to the enclosed notice, we hereby inform our patrons and the trade in general that all carbon cylinders furnished by us are manufactured under authority of the Holtzer patent, and that in using our battery no liability for infringement is incurred."

THE BOSSERT AUTOMATIC MAGAZINE FUSE BOX.

As fuses are liable to be blown at any time, it becomes a matter of importance to replace them quickly in order to avoid interruptions in the lighting or motor service. To effect the rapid substitution of a new fuse automatically, the Utica Electrical Manufacturing Supply Co., of Utica, N. Y., have brought out the automatic magazine fuse box illustrated in the accompanying engraving. This shows the fuse box with the two upper fuses burnt, and, as will be readily seen, as soon as one fuse is melted, another is, by gravity, thrown automatically in circuit. This it will do eight times before it is necessary to replace a fuse.



Bossert Automatic Magazine Fuse Box.

As soon as the four upper fuses are "blown" the first contact arm will be out of circuit and will throw the second arm automatically into circuit, thus giving a second magazine with four additional fuses. After the eight fuses in the magazine are blown in, there are still two main fuses which can be seen at the extreme right and left and connecting the circuit and magazine with a resistance coil placed in a circle on the inside of the case. These two fuses will eventually, if the circuit remains overloaded, blow also and open the circuit. There is no arcing when the fuse blows, because the instant the fuse melts, the current will make a circuit through the main fuses and resistance coil and take its regular course again as quick as contact is made with the fuse. The whole operation of "break" and "make" contacts is done so quickly that the eye can hardly perceive it.

To re-fuse the magazine it is only necessary to take off the brass nuts, seen at the extreme upper, lower and right-hand sides, loosen the set-screw next to the main fuse, and remove the line wire connected with the magazine; then the magagine can be readily taken out to re-fuse; to replace, both arms are moved up before putting the magazine in place, the circuit wire again connected and all is now ready for operation. As will be seen there are no magnets employed which might burn out and would entail extra work on the current. The contacts and conductors are made of bronze metal and of ample proportions, and the workmanship is first class in every respect. It can be used on either primary, secondary, or direct circuits.

Every station manager will readily see the benefit arising from the use of these magazine fuse boxes as they obviate to a great extent the dissatisfaction of customers and "cutting" of bills on account of lights being out caused by the melting of one fuse, a small matter apparently, but very often of large consequence. It will avoid the dangerous and risky work of linemen in climbing poles at night on a still hunt for the burnt fuse, trying to replace it while wires are alive. In short it will, if used on branches and centres of distribution, be a great boon to every one furnishing electricity for lighting or power purposes. The carrying capacity of the above described magazine fuse box is from 1 to 30 amperes. Special sizes are made to order.

THE SOUTHERN ELECTRIC CO.

Announcement is made by the Southern Electric Co., of Baltimore, Md., of the fact that it has secured the services of Mr. P. H. Alexander, of New York, as consulting engineer. It is now putting a large number of meritorious novelties on the market.

THE EICKEMEYER-FIELD STREET CAR MOTORS.

The following letter from Mr. N. B. Ream, of the Illinois Central Railroad, relates to the operation of the Eickemeyer-Field street car motors. This letter refers to the operation of the first large installation of standard double-connected motors made by this company:

Room 1163 The Rookery,
Chicago, March 14, 1892.

Mr. N. P. Otis,
New York City.

Dear Sir:—

In reply to yours of the 12th inst., would say, we have used the Eickemeyer-Field Motor on the Toledo Consolidated Street Railroads for the past year, and now have eleven in use, giving good satisfaction. They are simple in construction, and having no gears and few parts, and being in every way so well protected repairs are light, and hindrance to operation reduced to a small factor. The amount of current required in their operation is less than any motors we have had experience with, and when connected with both axles, we find them very efficient on curves and grades, and in pulling trailers. In our experience we are led to believe the Eickemeyer-Field motor to be in advance for economy as to power, repairs, and in efficiency, and to anyone interested in electric roads would say that it will well repay a visit to Toledo, where they can fully investigate their operation. We have been so favorably impressed with their operation that we have just placed an order for eleven more to be delivered by June 1st next.

(Signed) N. B. Ream,
President of the Toledo Consolidated Street Railway Co.

These motors are now regularly furnished by the Eickemeyer-Field Company, of Yonkers, N. Y.

THE ROY VALVE.

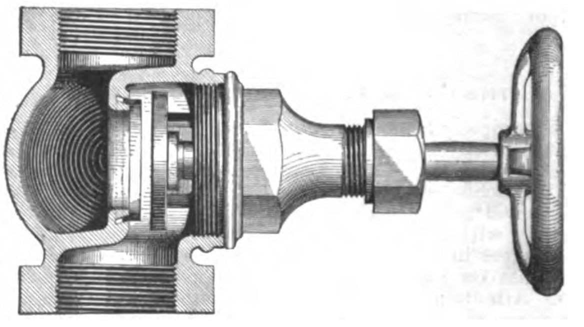
The accompanying illustration shows a new form of tight valve recently introduced by the Roy Valve Company, of 15 Cortlandt street, this city, which, the manufacturers claim, overcomes a number of difficulties met with in practice, and possesses numerous original features peculiar to itself.

It contains a method of making a joint that is a radical departure from the usual method, in a valve body, and assures a tight joint and makes a simple metallic joint which combines the essential features of a ball and socket, and of the expanded boiler tube joint.

It is simply a jointless ring of expansive material, inserted in the body, and as simple in application as a washer, resting on a conical base and making contact on its entire inner edge. When a pressure is put on the upper edge of the ring by means of a flat disc, the ring is forced outward and drawn inward to fill the depressions. The plane of the top surface of the ring remains undisturbed, but free to move laterally on the face of the disc. It is obvious that an extraordinary degree of distortion is provided for.

The ring is placed in the recess intended for its reception in the valve body, and the bonnet is then screwed down in the usual manner. As the circumference of the base of the recess is greater than its entrance, it follows that the ring will assume a degree of expansion similar to the base of the cone, and the elasticity of the ring in combination with the conical base of the valve, with the flat disc, will compensate for the usual distortion met with in practice.

The application of the ring is quickly made, and its removal, if injured by scale or grit, is by a pair of plyers, or similar means that will collapse the ring to a slight extent inwardly, and thus at once free it from the recess.



The Roy Valve.

Its continuous line of contact affords no outlet for the escape of fluid or gas, as is usual with threaded joints, and will, no doubt, with the other original features of this valve receive the endorsement of the engineering profession.

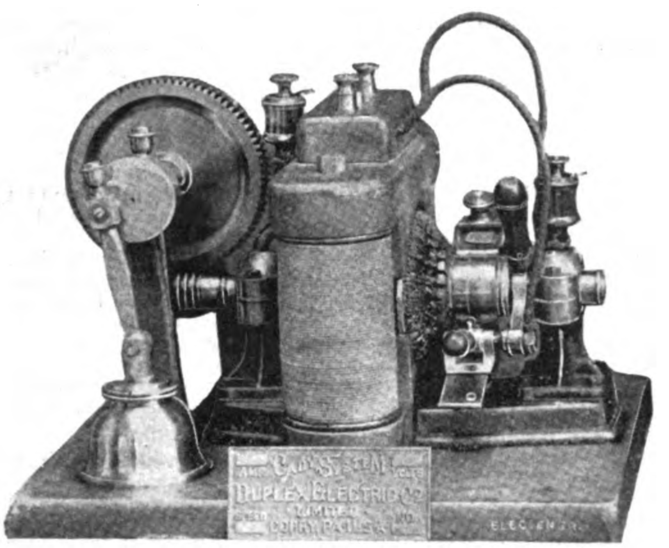
STEARNS MFG. CO.

Beginning on the 1st of May next, the Stearns Mfg. Co., of Erie, Pa., will establish a branch office in Chicago, which will be under the management of their Mr. A. F. Griswold, who has been with the firm for a great many years. Their office will be located in the Rookery Building, Room 1120.

THE DUPLEX ELECTRIC PUMP.

The accompanying illustration shows a combination ½ h. p. motor and pump in use for the past year at the Eureka mineral springs, Sagertown, Pa.

This little machine sits on a stone pedestal, about five feet high, in an open pavilion. It is run by a storage battery beneath the floor. The connecting wires being run through the pedestal, and the entire absence of spark gives it the appearance of a perpetual motion machine. When in operation it draws water from a depth of about 14 feet and throws one gallon per minute into a tank 150 feet away and 22 feet from the ground. The motor is wound for 110 volts and runs at a speed of 1,200 revolutions per minute, the armature shaft being geared to that of the pump in the ratio of 20 to 1. The entire floor space occupied is 16 x 18 inches.



The Duplex Electric Pump.

This combination was built by the Duplex Electric Co., Limited, of Corry, Pa., and like all of their motors and generators operates without rheostats.

THE EDISON BRANCH AT SPRINGFIELD, MASS.

An occasion of unsual enjoyment was that of a dinner given to members of the press and central station superintendents of Western Massachusetts and Eastern Connecticut by the Edison General Electric Co. at the opening of their new branch store at Springfield, Mass., on the evening of March 17. At an early hour a large number of invited guests assembled in the spacious and elegantly arranged store located at 219 Main street, and after having been shown the dynamos and motors in operation and having ample opportunity for looking over the large and complete stock and new fixtures, the entire company, under escort of Mr. Todd, the local manager, repaired to the private dining-room of the Cooley House. The table was prettily decorated with flowers. Groups of colored miniature incandescent lamps were hidden beneath the blossoms and leaves, and abundant light was afforded by the small lamps. After having leisurely discussed the several courses provided, various toasts were drunk, among which were those to the Edison General Electric Co., the Springfield store and the press. In reply to these several toasts, Mr. Kimball of the supply department of the New England district introduced Mr. Knight, the district auditor; Mr. Anderson of the Springfield Co.; Mr. Todd, manager of the new store; Mr. Smith representing the press, and Messrs. C. C. Pierce and S. A. Douglas representing respectively the street railway and the central station departments of the New England district.

These gentlemen replied in very happy vein to the various subjects to which they were called, and the remarks together with instrumental and vocal selections rendered during the evening kept the company at table until a late hour.

The opening of the new store which is the first of its kind in Springfield marks a decided advance in the business of the Edison General Electric Company. The sales of that corporation have steadily grown during the past until it became necessary in order to properly attend the wants of its numerous customers that districts should be organized , and now in order that the districts may still further cover the ground in a more satisfactory manner sub-stores are being established in some of the larger cities and towns throughout the jurisdiction of the various district managers. While the banquet of Thursday was very informal in its nature, it proved one of the most enjoyable occasions to which the gentlemen present had ever been invited, and in leaving, the heartiest and most unanimous expressions of satisfaction were tendered the representatives of the Edison Company for so satisfactorily providing for their guests and friends.

ENGINEERING EQUIPMENT CO.

The annual meeting of the stockholders of the Engineering Equipment Co. was held March 19, 1892, in the Hudson County Bank Building, Jersey City, N. J., and the following board of directors elected : Mr. C. A. Tinker, F. H. Underwood, A. L. Tinker, E. L. Harriot and F. A. Magee. Mr. A. L. Tinker was elected secretary and treasurer, and E. A. Magee, general manager. Mr. Magee will retain his position in Boston.

QUEEN & CO.'S ELECTRODYNAMOMETER.

Some time ago this enterprising firm placed on the market a new type of electrodynamometer which, we learn, has met with great favor. By the adoption of an agate bearing instead of fibre suspension as formerly used, the element of torsion is eliminated, and greater accuracy is obtained in consequence. These instruments are extensively employed as absolute standards in measuring both direct and alternating currents, and are especialy suited for use in central stations as checks for the ordinary commercial ammeters.

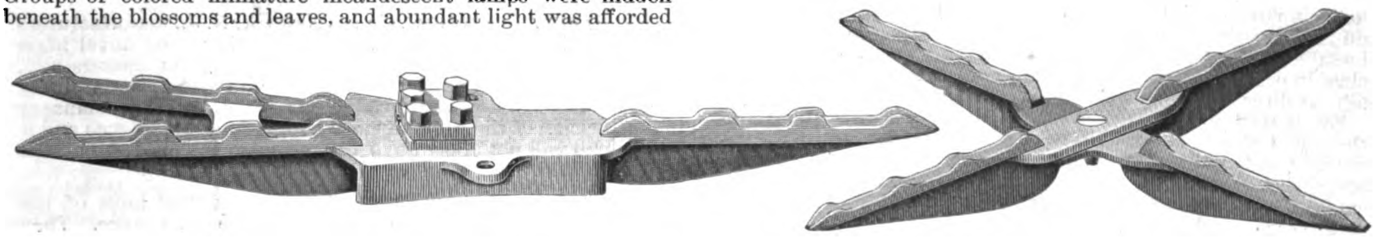
THE TORONTO INCANDESCENT ELECTRIC LIGHT CO.

The stock of the Toronto Incandescent Electric Light Co., Ltd., is selling on the Toronto Stock Exchange at 20 per cent. premium. This company commenced operations two years since, and now has a paid-up capital stock of $500,000. A 6 per cent. dividend has been paid since the start.

THOMSON-HOUSTON STANDARD PATENT SWITCHES AND CROSSINGS.

In the overhead wires of an electric street railway there must be a switch or frog to correspond to every switch or frog in the track. These overhead frogs must be as light as is consistent with the necessary strength, and they must be so constructed as to fulfil their purpose with certainty. The frogs manufactured by the Thomson-Houston Company are claimed to possess these qualities, besides being light and strong, easily put up, and certain in their operation. The forms shown in the accompanying illustration have been designed to meet all the conditions of line construction.

The standard frog, Fig. 1, made in the form of a **Y** is best suited to most requirements ; but frogs are also provided for right-hand and left-hand switches, and a three-way frog for double-branch switches. The trolley wire is soldered into the grooves between the clips on the tongues of the switch, and is also firmly clamped by the screws and metal cross-pieces on top of the frog plate. Provision is made at the sides for the attachment of cross suspension wires.



Figs. 1 and 2.—Thomson-Houston Standard Switch and Crossing.

Where two overhead wires cross each other a similar arrangement to the frog is used, with only slight changes necessary to adapt the apparatus to the different conditions met. Two forms of this apparatus are made, one of acute angle crossings, and the other for crossings at an approximate right angle. Both forms are made to swivel, so that the tongues will adjust themselves to the exact angle at which the wires cross.

NEW YORK NOTES.

Messrs. W. H. Gordon & Co., 115 Broadway, wish it distinctly understood that they have not gone out of the wire business. A recent notice in one of the trade papers mentioning the severance of one of their connections is calculated to create a wrong impression. They wish their friends to bear in mind that they have even greater facilities than heretofore for furnishing them any grade or kind of wire they may need. It should be borne in mind that on bare and insulated wire, line material, lamps and several other specialties, Messrs. W. H. Gordon & Co. are manufacturers' agents and are selling at factory prices.

The Norwich Insulated Wire Company have just closed a large contract with the United States Electric Light Company of Washington, D. C. This contract will aggregate about thirty miles of the above company's wire. Mr. F. Day Voorhees, general sales agent of this company, has just returned from quite an extensive trip throughout the West in the interests of his company, the result being the bagging of some very handsome orders.

The Dreher Manufacturing Co., manufacturers of high grade lubricating oils, will shortly remove to new and more desirable quarters at 249 Front street. This company is in receipt of some flattering testimonials regarding its specially refined oil for dynamos, etc. The trade with electrical concerns shows a wonderful growth in the last few months.

The Standard Paint Company are sending out a very neat catalogue and price list of their specialties. This little work is dedicated to the electrical fraternity particularly, and besides giving directions for the application of their well-known compounds, etc., it contains a number of congratulatory letters from those who have used these goods.

The Interior Conduit and Insulation Co., of 42 and 44 Broad street, have issued a "Cautionary Notice" to architects, builders, owners, etc., which defines their position as to interior wiring patents, and dwells at some length on the validity of their claims. It contains also copies of the injunctions recently obtained in New England.

The Short Electric Railway Company announce recent sales to the Braddock Electric Railway Co., Braddock, Pa.; the Union Passenger Railway Co., Chester, Pa.; The Fort Wayne Electric Railway Co., Fort Wayne, Ind.; the Schuylkill Electric Railway Co., Pottsville, Pa.

Mr. C. H. Davis, C. E., of 120 Broadway, has issued a neat little folder called "Facts and Figures" relating to matters of interest to all concerned in electric railroading. It is very meaty and valuable.

The Indurated Fibre Pipe Co. have removed from their old offices in the Central Building, and will hereafter be found in a very desirable suite of offices in the Aldrich Court, 45 Broadway.

Mr. Henry Alexander, the treasurer of Alexander, Barney & Chapin, has tendered his resignation and will sever his connection with the company April first.

PENNSYLVANIA NOTES.

The Harrisburg Foundry and Machine Co. are adding $30,000 worth of new machinery to their factory, and expect in a short time to increase their present large production. The Ide and Ideal engine built by them are meeting with the strongest recommendations for economy, strength, regulation and general efficiency. The company has recently sold a 400 h. p. cross-compound engine for the Post Engineering Co., of Boston, one 250 h. p. tandem compound engine for the Central Iron Works of Harrisburg, together with some 30 engines both compound and simple for New York, Philadelphia, Boston and electric companies throughout the United States. The company are also doing a large business in boilers, and have just sold ten 100 h. p. return tubular boilers with Westmeyer furnaces for the Central Iron Works, of Harrisburg; six 100 h. p. return tubular boilers for the Paxton Rolling Mills, Harrisburg; two 100 h. p. return tubular boilers with Westmeyer furnaces for the Morrison & Carr Paper Co., of Tyrone; also numerous other boilers ranging in size from 40 h. p. to 80.

The Eureka Tempered Copper Co., of North East, Pa., are running to their full capacity, and are compelled to work night and day to meet the growing demand for their specialties. They report large orders, and have orders booked from one firm alone for over fifty thousand commutator bars. They have made arrangements with O. Berend & Co., 61 Fore street, London, E. C., to handle their goods exclusively in the United Kingdom. They have also established an office in Vienna, and are already doing a large business in Europe.

Mr. Otis K. Stuart has accepted the agency for the Duplex Electric Co., of Corry, Pa., who manufacture the Duplex motors, dynamos and arc lamps.

Partrick & Carter Co. announce that the Disque battery has many points of superiority that have given it a well-earned reputation for reliability. Improvements have been lately added which greatly increase its efficiency and cleanliness. The lead top connection and covered cell are new features that will recommend themselves to every purchaser and user of open circuit batteries. The new form is shown in the firm's advertisement this week.

The East Harrisburg Passenger Railway Co. are about to duplicate their present plant and will add several miles of track, new cars and 450 h. p. Wetherell cross-compound condensing engine. This company are using the Groetzinger "Dermaglutine" pinions on their motors. One of these shown your representative had run over 57,000 miles and is still in use.

WESTERN NOTES.

Electric Merchandise Co.—A fair index of the great amount of business in sight in the electric railway line can be found at the office of the Electric Merchandise Co., Chicago. As the company confines its business strictly to electric railway supplies, it is perfectly natural for street railway men to call and examine the standard appliances handled by it. In fact, No. 11 Adams street has become general headquarters for all interested in street railway matters. The prompt and careful attention given to orders is appreciated by the managers of street roads, and accounts to a great extent for the popularity of the company. Owing to largely increased facilities, the company is better fitted than ever to meet the growing demands of the trade.

The Electric Appliance Company have been mailing a circular containing a description of the "swinging ball lightning arrester," with a few of the numerous testimonials received, to the Western trade. They report that judging from the number of replies received from persons familiar with the merit of the device and who state that they will use a large number of them this spring, they are sure of orders that will test the capacity of the factory.

The Central Electric Company report the sale of three underground cables of the Okonite manufacture within the past week. From the many proposals that are out, they expect to be busy in this department very shortly. They are preparing to put on the market an absolutely dust-proof bell, one that will be perfect in every respect.

NEW JERSEY NOTES.

The Suburban Electric Co., Elizabeth, N. J., organized last December with $350,000 paid up capital, and consolidating all the electrical interests of Elizabeth and Roselle, are building a new station at the foot of Murray street beside the Elizabeth River. The building, designed by Mr. E. P. Ball, of Palmer, Mass., will be 87 x 225 feet, of two and three stories of the most approved modern type, with engines capable of being run either condensing or non-condensing. The plant and most of the apparatus is intended for double the capacity at present required. Three compound condensing engines of Corliss type will be used, taking their steam from vertical fire-tube boilers. The station capacity at the start will be for 200 arc lamps, 8,250 incandescent, and 80 h. p. of motors; furnished by Thomson-Houston, Edison and Westinghouse dynamos. More generators will, however, be needed soon, and in all about 225 miles of feed wire will be used. The Edison mains are for the most part underground. The directors hope to have the plant in operation by May.

The Safety Electrical Co., of Newark, N. J., manufacturers of general electrical specialties, are introducing some novel ideas in the construction of their new bells, annunciators, buzzers, etc., for which they claim particular excellence in principle, simplicity of construction and workmanship. Mr. R. J. Britton, manager and electrician of the company, has had years of experience and is a man who will not allow anything put upon the market but the best in his line.

Jersey City.—The patronage of the new power lines of the Jersey City Electric Light Co. is getting to be very large. They have have among other motors recently placed a 60 h. p. motor in the F. O. Matthiesen flour mills. The company has had much trouble with the quality of water supplied, but are at present using a Hopping waste water purifier with success.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XIII. APRIL 6, 1892. No. 205.

A DIRECT CURRENT TRANSFORMER PLANT AT OLYMPIA, WASH.

BY

R. Fleming

LIKE a great many other Western towns, Olympia, the capital of the new State of Washington, rejoices in the possession of an adjacent waterfall, which, thanks to the enterprise of Mr. E. T. Young and his associates, of the Olympia Light and Power Co., is being utilized to furnish light and power to the city and its inhabitants. The waterfall is two miles distant on the De Schutes River, which, after a rugged and picturesque journey from its source in the great glaciers of Mount Tacoma, drops abruptly eighty feet into the placid waters of Puget Sound.

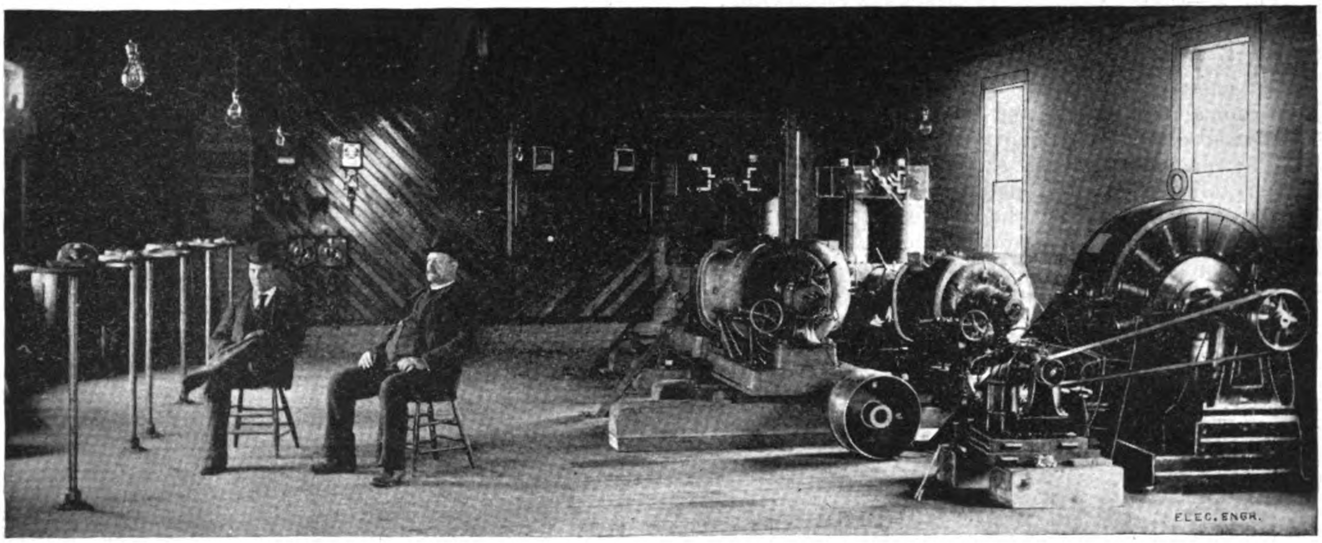


FIG. 1.—POWER HOUSE OF THE OLYMPIA LIGHT AND POWER CO., OLYMPIA, WASH.

The company furnish arc and incandescent lighting, and are now preparing to build several miles of street railway to connect Olympia with the neighboring town of Tumwater. The arc machines in use are of the new Edison type; these have now been running nearly a year, and are giving excellent service.

Both alternating and direct current transformer systems are employed. Though the latter system has been repeatedly set down as impracticable, it is here doing all that could be desired, and is both practical and efficient; the sole objection to it being that of requiring attendance at the sub-station. This item is, in a small plant, of course, objectionable.

The arrangement is as follows: Two 60 K. W. Edison 500-volt generators are placed at the power house, shown in Fig. 1, and are so arranged that by throwing a switch they can be grouped in multiple, or in series, as desired, and a two or three wire system can be used, the ground acting as the neutral conductor. Power for running the sub-station is taken from the "outside" wires at a pressure of 1,000 volts. Ordinary motors are connected between either outside wire and the ground. The distance from the power station to the sub-station is over two miles.

The transformer plant at the sub-station, Fig. 2, consists of one 80 K. W. motor, Edison type, driving by means of belts in tandem two smaller compound-wound dynamos of the standard incandescent type. These supply current to the network of wires on the lines on the usual three-wire system.

Though this arrangement seems complicated, and to require considerable machinery, yet the results obtained are all that could be desired both in point of efficiency and regulation and will compare favorably with any other system of transformation. The regulation is far better than can be obtained with alternating converters. This plant has been running now for almost a year without a hitch, even though the output has been at times far above the overload limit. The object of the company in adopting this system was to enable them to obtain power for motors and lighting purposes from the same generators. For lighting purposes alone, this arrangement could have been simplified considerably by using one generator instead of two, and increasing the voltage.

Some months ago the gas and electric company and the above-named company consolidated, using the name of the Olympia Light and Power Company. The gas company's plant consisted of one fifty-light Thomson-Houston arc dynamo, and one 1,300-light alternator of the same make. The latter was transferred to the water-power sta-station, while the arc machine, together with a 75 h. p. Russell engine, was held as a reserve at the old station, arrangements being made to connect this machine with either arc line at will.

The water wheel plant from which power is derived consists of two pairs of 15-inch Victor horizontal wheels, both connected to the same shaft, on which are mounted six friction clutch pulleys and two heavy balance wheels. Wheels and clutches are controlled from the dynamo floor above by means of upright shafts and hand wheels. All the hydraulic machinery, including wheels, shafting, etc., and flumes, was built by the Stilwell & Bierce Manufacturing Company, of Dayton, Ohio. All the electrical construction was done by the writer for the Edison General Electric Co., Pacific Northwest District.

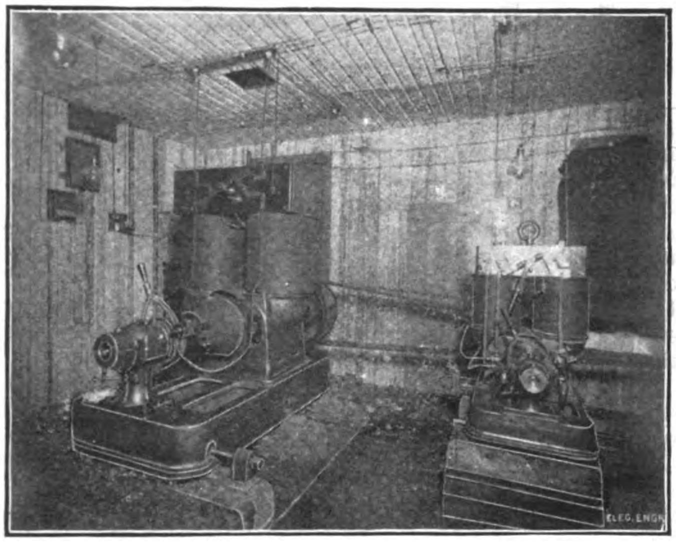

FIG. 2.—DIRECT CURRENT TRANSFORMER SUBSTATION, OLYMPIA, WASH.

A NEW METHOD OF DUPLEX TELEGRAPHY.

BY

Jno. J. Ghegan

ALTHOUGH the ordinary systems of duplex telegraphy are generally said to double the capacity of a line it must be admitted that they have been up to the present incapable of doing it. They are only capable of sending two messages at the same time, in opposite directions and between terminal stations, and "breaks" can only be made by interrupting the opposite side.

To actually double the capacity of a wire, two complete and independent circuits should be so formed that intermediate offices can be on either or both of them, and so that any office on the line can send two messages in the opposite direction or in the same direction at the same time, thus constituting both a duplex and a diplex. The writer undertook to devise such a system, and actual tests have demonstrated the possibility of filling all the requirements mentioned above.

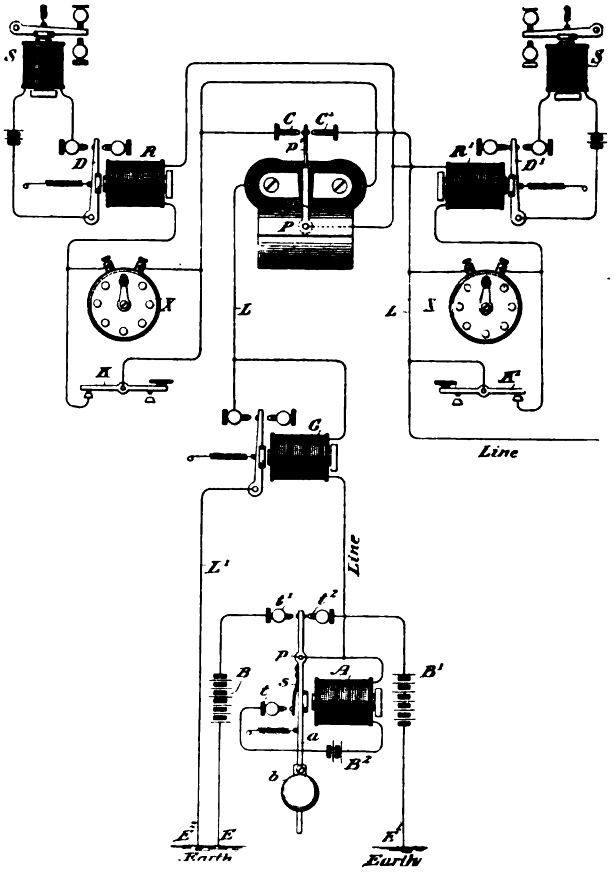
The only changes required to make the ordinary instruments available for this system is to reverse the contact points of the keys and relays, and even these changes can be dispensed with under a slightly different arrangement. The stations would, however, have to be provided with rheostats and polarized relays in addition to their ordinary instruments.

But one main battery is required and that can be located at any station on the line. The battery station is also provided with an automatic pole changer, which sends rapidly alternating pulsations to the line. These pulsations are separated at each office so that the positive pulsations pass through and actuate one set of instruments and the negative pulsations actuate the other set.

The signals are transmitted by varying the resistance of the line for the pulsations of either polarity without interfering with its normal resistance to pulsations of the opposite polarity.

This will be better understood by reference to the accompanying diagram which represents the arrangement of a station with main battery at one end of the line. The upper portion shows the arrangement of the apparatus at all the other stations having instruments on both sides of the duplexed line. Two main batteries are shown in the lower part of the drawing, but with proper connections to the pole changer one is sufficient, or an alternating dynamo may be substituted for the battery and pole changer.

It will be noticed that between the pole changer and the line a relay G is placed and that the line, after passing through this relay is in connection with its back-stop, and that the relay armature is connected to the earth. This earth contact through the back-stop of the relay is employed to discharge the line after each pulsation. Each station is provided with a polar relay P, neutral relays R R', keys K K', local sounders S S', and resistance boxes X X', arranged as shown, the resistances being located in shunt around the keys K K'.



THE GHEGAN DUPLEX TELEGRAPH SYSTEM.

The operation of the system is as follows: The armature of the polarized relay P vibrates between the stops C C' at each change of polarity due to the action of the pole changer and batteries at the battery station; the neutral relays R R', and the rheostats X X′ are also in circuit with the polar relay P. It will be noticed that the armature and contact points C C′ of the polarized relay P are so connected that they shunt or cut out one or the other of the neutral relays R or R′ with its corresponding rheostat and key K or K′, according to which of the points, C or C′, is in contact with said armature. Therefore as the armature of the polarized relay responds to the changes of polarity of the pulsations sent to the line, it alternately shunts or cuts out the neutral relay R or R′ so that one of them is influenced by the positive and the other by the negative pulsations only, and consequently any variation in tension or current strength of the positive pulsations will only affect the corresponding neutral relay, and vice versa.

These neutral relays R R′ are so adjusted that by throwing in circuit a suitable resistance X or X′ the tension or current strength is so varied that their armatures fail to respond to the weakened pulsations and are drawn against their back-stops. The resistance thrown in need not be sufficient to prevent the armature of the polarized relay P from responding. The resistance being only in circuit while its corresponding set of relays are also in circuit, it consequently does not affect the relays which correspond to the opposite pulsations.

Depressing a key interrupts the low resistance path of the circuit around a rheostat and thereby changes the current tension at each recurring impulse of the corresponding polarity, so that the armatures of the neutral relays which are in circuit for the weakened impulses remain on their back-stops, and close their local circuits as long as the key is head down.

Thus it will be seen that all the sounders S will receive signals by the varying of impulses of one polarity, while sounders S′ will receive signals by varying the impulses of the reverse polarity on actuating the keys K K′, respectively. It is obvious that with this system each side of the duplexed line is independent of the other; that way, or intermediate, as well as terminal, offices can be on either or both sides, and that two messages can be sent at will in the same, or in opposites, directions at the same time.

MEASUREMENTS OF THE HYSTERETIC LOSS OF MAGNETIC ENERGY IN NICKEL.

BY

A. E. Kennelly

THE energy absorbed in hysteresis by substances under reversals of magnetization is probably measured most conveniently by the use of a wattmeter with an alternating current. This method cannot be employed when the Ewing *H B* diagram, or the relation of flux to field, is required, but where only the integrated area of that diagram or the hysteretic energy per cycle is needed for definitely varying maximum flux densities, the convenience, swiftness, and precision with which the observations can be carried out give it great advantages.

Measurement was made of the hysteretic loss of energy in two samples of good commercial nickel wire, each wound up in a coil or Faraday ring. The connections are shown in the Fig. 1. P and S are the primary and secondary coils of a transformer operated by an alternator with an average and nearly uniform frequency of 141.6 ~. The regulation of the alternator fields controlled the E. M. F. in the coil S, whose circuit was closed through the ammeter A, the fixed coil of a dynamometer wattmeter D, and the insulated winding of the nickel wire ring R. The suspended coil *c* of the dynamometer was permanently connected through an adjustable resistance *r* across the terminals 1 and 2 of this ring. Before and after each wattmeter observation, the Weston alternating current voltmeter V was also connected to the terminals 1 and 2, and a reading of the pressure taken.

The dynamometer was a nearly dead-beat, unifilar torsion instrument, read off by telescope, mirror and scale, Its suspended coil having eight ohms and three millihenrys, in circuit with the resistance *r* of from 1,000 to 6,000 ohms according to the pressure, it is evident that the error in the readings due to lag in the suspension circuit was negligible. The instrument was also sensitive, and gave about 20 degrees of twist per watt of indicated power.

It is worthy of remark that the use of such alternating current wattmeters has been often avoided on the ground of inductance error, but when made with sufficient sensitiveness to need only small inductance with high resistance in the suspension circuit, the charge is unfounded, and their indications in power measurements become reliable. For if *c* be the current passing through the fixed coil, and *s* that in the suspension, under an effective pressure *e* through a large resistance *r*, with a total inductance *l*, the maximum error in watts that *l* can effect in the readings with a pulsation $p = 2 \pi n$ is,

$$r\, s\, c \sin \tan^{-1} \frac{pl}{r}, \;\ldots\ldots\; \text{or very nearly} \;\ldots\ldots\; e\, c\, \frac{pl}{r}.$$

In other words, the maximum error would be the apparent watts or product of volts and amperes multiplied by $\frac{pl}{r}$, while the actual error is generally much below this limit.

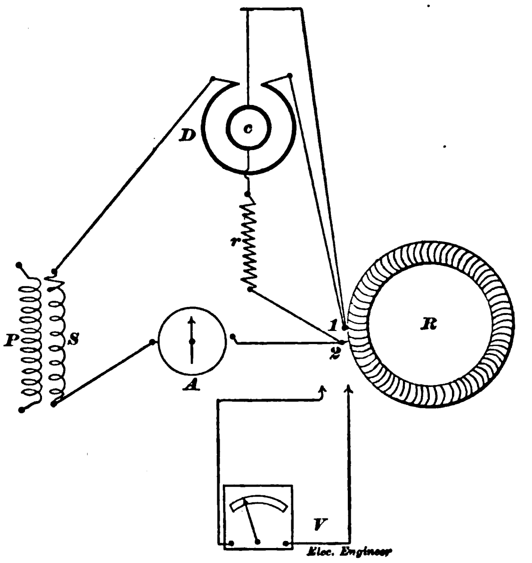


FIG. 1.

The particulars of the rings are given in the following table. The weight of nickel in each was the same, but the diameters of the nickel wires were different. The winding of insulated copper wire was also the same on each:

	Coarse wire ring.	Fine wire ring.
Turns of wire,	570	between 4,000 and 5,000
Diameter of wire,	0.0365″ 0.0927 cm.	0.0126″ 0.032 cm.
Sectional area of wire,	0.006749 sq. cm.	0.000804 sq. cm.
Weight of wire in ring,	2,255 gms.	2,255 gms.
Volume of wire in ring,	253.3 c. c.	253.3 c. c.
	Cross-section of ring.	
By number of wires,	3.848 sq. cms.	
By external dimensions,	3.852 "	3.852
Mean diameter of ring,	20.93 "	20.93 cms.

Winding..... ....700 turns of copper wire on each ring.
Resistance of winding at 18° C..................2.815 ohms.

Before applying the copper wire winding to these rings, they were well soaked in melted paraffine wax, with the object of limiting all eddy currents as much as possible, although previous tests on the rings without this precaution do not by comparison show appreciable loss from eddies when the bare nickel wire was used. Some 200 grammes of paraffine wax was absorbed into the rings.

In reducing the measurements, the wattmeter readings were corrected for the extra incidental losses of power, namely, $\frac{e^2}{r}$ in the suspension circuit, and $c^2 R$ in the ring. The balance gave the loss in hysteresis assuming no loss in eddies. The voltmeter pressures at ring terminals reduced by $c R$ gave the counter E. M. F. of the ring, from which the maximum flux density in the nickel was determined on the assumption of a simple harmonic E. M. F.

The accompanying curves show the resulting ranges of hysteretic loss per c. c. of nickel for the two rings at varying flux densities. The loss is nearly 25 per cent. greater in the coarse wire. The curves agree very fairly, however, with the law of $\frac{8}{5}$ exponent, as lately enunciated by Mr. Steinmetz[1] for iron, the dotted lines representing the locus of this exponent drawn from the datum point for $B = 1,500$ on each curve. The hysteretic loss in ergs per c. c. per cycle for the coarse wire is thus apparently 0.00125 $B^{\frac{8}{5}}$ for the coarse wire, and 0.00101 B for the fine, between the limits of 0 and 3,000 of maximum cyclic flux density.

There are two reasons for believing that this difference between the absolute values of the hysteretic loss in the two rings was not due to eddy current influence; 1st, that, as above mentioned, the loss of energy was not found to increase when no paraffine was used to insulate the wires; and 2d, that eddy current influence would introduce a term varying as B^2, and the resulting curve would diverge from a curve of $B^{\frac{8}{5}}$.

The hysteresis was quite definite in each ring, and any reading could be reproduced at will, by adjusting to the right pressure at the voltmeter. Eight series of measurements were made in this way at different times, four series on each ring. The results seem to show that, approximately at least, the hysteresis in nickel varies, as in iron, with the $\frac{8}{5}$ power of the maximum flux density, although the difference in the coefficient would indicate some latitude in the amount of hysteretic dissipation with different specimens. As with iron therefore, doubling the flux density in nickel, practically trebles the hysteretic loss.

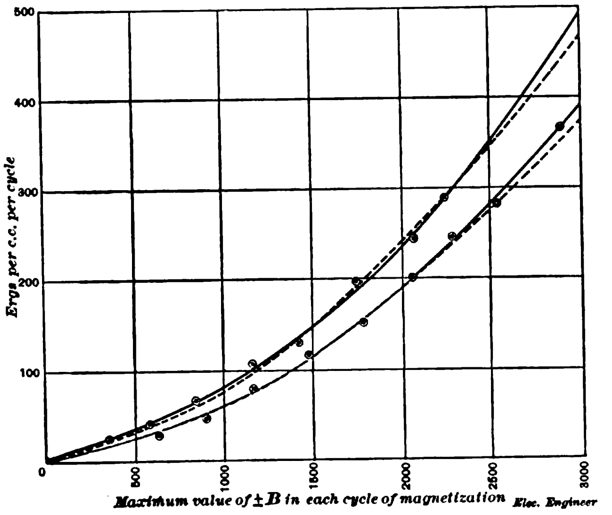

FIG. 2.

The writer is indebted to Mr. A. Hoopes for assistance in carrying out this measurement at Mr. Thomas A. Edison's laboratory.

MR. TESLA'S EXPERIMENTS.

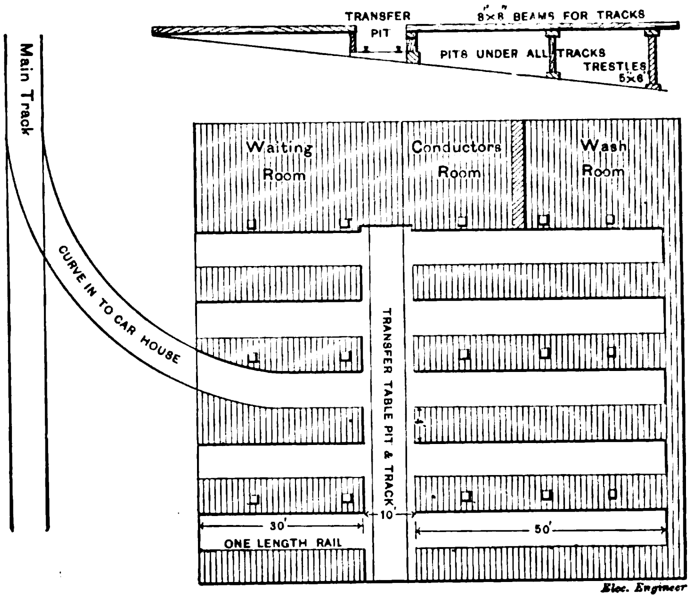
"THE French papers this week are full," says the *London Electrical Engineer*, "of Mr. Tesla and his brilliant experiments. No man in our age has achieved such a universal scientific reputation in a single stride as this gifted young electrical engineer."

ELECTRIC CAR HOUSES.

BY

A. K. McCay.

A GREAT deal of electric railroad construction is now being contemplated, and a few practical points as to car houses and their appointments may be in order. Of course, the shape and size of the lot will frequently decide the size and shape of the car house, but the architect who designs the same rarely has practical experience in aiding him in the work. To arrive at practical results and figures I will describe a car house designed and built by myself during the past year which has proved eminently satisfactory. The plot of ground was 150 x 100 feet, the 150 feet facing the main line. This plot was situated at the extreme end of the line.



FIGS. 1 AND 2.—ELECTRIC CAR HOUSE.

Fig. 1 shows the ground plan of tracks, giving the position of transfer pit and rooms; 60 x 100 feet deep was decided as ground to erect the car house upon. A curve was thrown into the centre of this 60-foot plot, and the tracks placed as shown. The ground on which this car house was built sloped gradually away from the street, being 9 feet lower at the rear than at the street. I decided to trestle all tracks from the transfer pit back. This arrangement, shown in Fig. 2, gave free and full access to every portion of the bottom of the cars and allowed plenty of room for removing gears, etc. Four feet was left between each set of tracks and only five sets of tracks were laid. These were laid on trestles, which were built of 5 x 6 inch hemlock, pinned together as shown in Fig. 2A. On the top of

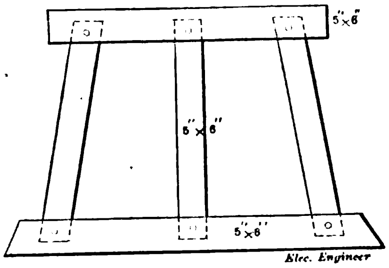


FIG. 2A.—ELECTRIC CAR HOUSE TRESTLE.

---

[1] "On the Law of Hysteresis." A paper by Mr. C. P. Steinmetz read before the American Institute of Electrical Engineers, Jan. 19, 1892.

these were placed an 8 x 8 inch beam, on which was spiked the rail. The space between the sets of tracks was floored over, and cross-overs were placed between tracks at convenient intervals.

The space of 37½ feet was left between the front wall and centre of transfer-table pit. This allowed a single length of rail to be placed on each of the other tracks and one car kept on these, without any cutting of rails. These five tracks accommodate some 15 16-foot cars, with room for three more if desirable, when the waiting-room, conductors' room and washroom will have to be removed for the sixth track.

The workroom was equipped with a lathe and all necessary tools. The conductors' room was furnished with two beds, so that I could always have men present at the car house at all hours of the night. This convenience was appreciated several times when a heavy snowstorm came up and steps had to be taken to clear the track.

The height of this lower room for the cars was 20 feet; this allowed the trolley poles to go well up at night, and prevented a continual strain on the springs. The car house was well lighted, having thirty windows, 8 x 3 feet, distributed around the entire four sides. A well-lighted car house is essential to good work on the cars, and too much attention cannot be given to this point.

I decided to build my own transfer table, shown in Figs. 3 and 4, and for that purpose took three pairs of old street car wheels and axles, and built up on their boxes a heavy flat car. The wood used was maple, and was thoroughly bolted together, as shown in the sketch. The springs were taken out of the boxes, and heavy blocks of hard wood were wedged in above the axle. This gave the car rigidity and did not allow it to drop when the weight was placed on it. Beneath the three boxes on each side was bolted, as shown, a flat iron bar, 2 inches wide and ½ inch thick, which assisted the heavy beam above the boxes in preventing a racking motion. Heavy 2-inch boards were nailed on top of the longitudinal beams in two layers. Then the tracks were spiked down. The whole cost of the car, exclusive of wheels, was about $26, and it has been a marked success.

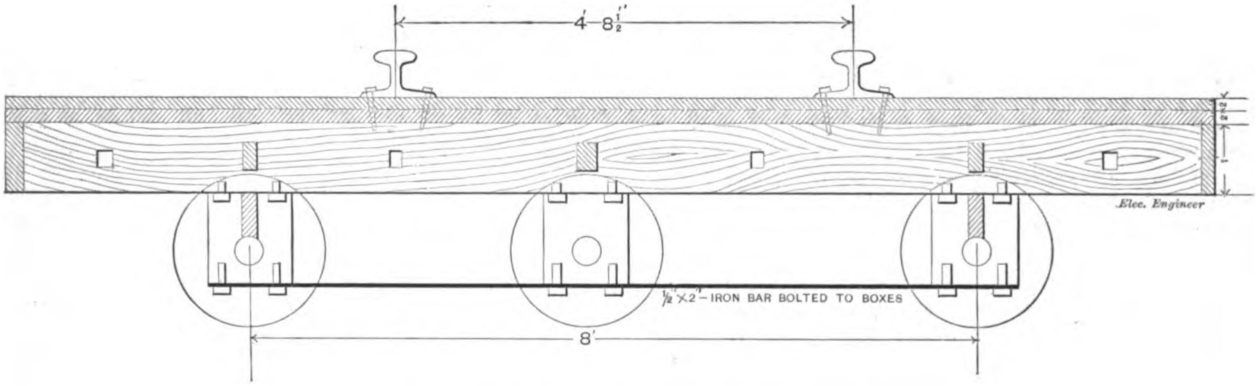

FIG. 3.—TRANSFER TABLE FOR ELECTRIC STREET CARS.

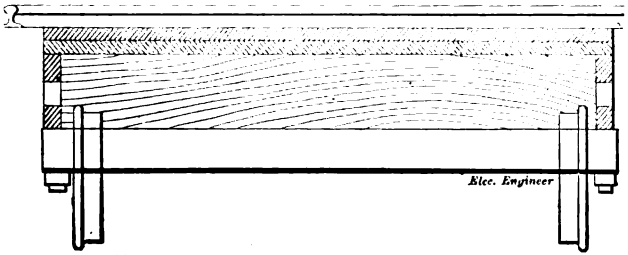

FIG. 4.—END VIEW OF TRANSFER TABLE.

The three sets of wheels per side made the table very easy to move, even when having a heavy vestibule car on it, and a simple lever-locking device, arranged to be worked from the side of the table was used to hold the car in place. The table was always kept opposite the middle track, so that a car coming in from the main track could not plunge into the pit. This transfer pit was used quite often when plenty of room at the end of a car was desirable, the car being allowed to project over the transfer pit. This was found to be very handy and will be appreciated by any one who has had to take off the axle-gear in a cramped pit.

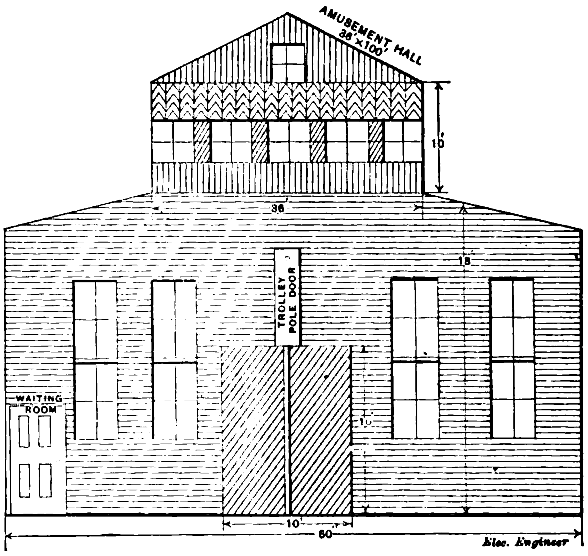

FIG. 5.—ELECTRIC CAR HOUSE.—FRONT ELEVATION.

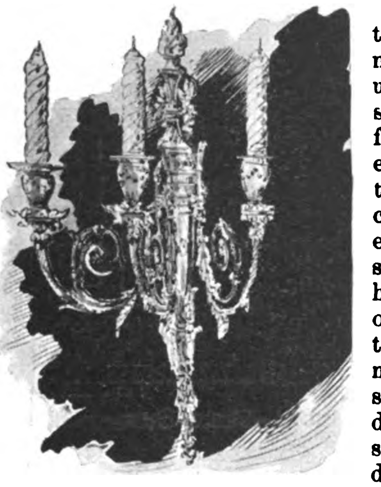
As stated above, the car house lot was at the extreme end of the track; this fact led to the adding of a second story to a portion of the car house for an amusement hall, access thereto being gained by a stairway from the waiting-room. This proved to be very valuable for concerts, entertainments, fairs, etc., completely repaying for the additional expense necessary to build it. And I should strongly advise any company building a car house at the end of the line, or at some distance from the centre of the city, to lay out the additional money; it will pay, and pay well.

These are the salient features of this particular car house. Since building it I have visited many others, and while I have seen the same principles differently embodied, I have seen none in which repairs and cleaning could be done so easily and so readily. The house was built of wood, finished inside with Georgia pine, the total cost being less than $4,000. On account of being built of wood, a standpipe, 4 inches in diameter, was run in from the street mains and carried up to the second story; this was provided with 100 feet of fire hose. This precaution, together with the fact that there were men in the building at all hours, materially lessened the cost of insurance. Fig. 5 shows a front elevation of the car house.

THE STATUS OF LIGHTING COMPANIES IN MASSACHUSETTS.[1]

BY

Franklin Leonard Pope



THE annual report of the Massachusetts commissioners contains, as usual, a vast amount of statistical and other useful information, in reference to the operations of the local illuminating companies for the year ending June 30, 1891. It still remains true, as I have heretofore had occasion to point out, that the manner in which this matter has been presented leaves much to be desired, inasmuch as a small amount of additional labor might have added greatly to the usefulness of the work, considered as a whole. For example, if one wishes to ascertain the aggregate number of dynamos, or motors, or incandescent, or arc lamps in use in the State, he must resort to the laborious operation of footing up the figures as separately reported by each company, which ought of course to have been aggregated, once for all, by the compiler of the report.

The returns made by the several companies are tabulated in accordance with a schedule of instructions issued by the board in 1887. In returning the "cost of works" the instructions provide that "this account should show, either in detail *or in one construction account* the cost of the company's works, including real estate, steam plant, electric plant, meters, lines, lamps and globes." It results from the alternative direction which we have italicized, that there is considerable diversity in the way these accounts have been made up, a circumstance which is particularly annoying to the comparative statistician. It would be altogether preferable if the separate items of the construction account were required to be reported separately and in detail by all the companies, as they now are voluntarily by many of them. It would moreover be an excellent idea if the various State boards, and the National Electric Light Association could agree upon a uniform schedule for reports of this character, to be made by all the companies in the country.

Not only is there no increase in the number of electric light companies operating in the State since last year but owing to consolidations there appears to be a net decrease of two. It is quite clear, from a study of the returns, and of the profit and loss accounts (published for the first time last year), that there is not likely to be any material increase, from this on, in the number of electric light companies operating in the state. Electric lighting has apparently been introduced into every town and village in the state in which there was any chance of a profitable business, and indeed the balance sheets show that in a considerable number, especially of the smaller towns, the expectations of the promoters of these enterprises have by no means been realized. Such of the companies as have succeeded in establishing a paying business, are nevertheless enlarging their field of operations as rapidly as possible, so that the industry as a whole may be said to show a very gratifying progress.

In 1887 the legislature of Massachusetts passed an act authorizing such gas companies as should first have obtained the consent of the Commissioners, to furnish electric light. From the present report, it appears that up to June 30, 1891, of the 70 chartered gas companies in operation in the State, 26 had undertaken to furnish electric light also. A subsequent act was passed in 1891, authorizing cities and towns to manufacture and distribute gas and electricity. It appears from the report that of the 210 towns and cities in the State having a population of 1,500 or more, 180 have taken no action in the matter. In most of the places in which action has been taken the voters—as I think, wisely—decided not to embark in the business. Danvers appears to be the only municipality, thus far, which has an electric plant in actual operation, and this is merely for street and not commercial lighting. The whole number of municipalities maintaining public electric lights is 79. Of these, five use the incandescent light, 74 the arc, and 41 use both. The total number of commercial incandescent lamps reported is 161,259, as against 118,529 the preceding year, an increase of nearly 37 per cent., which is a very good showing. Twenty-five companies have paid dividends this year as against 22 the preceding year. The total of dividends paid foots up $262,958, as against $154,708 the preceding year, an increase of 78 per cent. These figures show clearly that the financial situation of the well-established plants is improving rapidly with the increase in their business.

The effect of the competition of the electric light on the sales of gas by meter is observable principally in the check which it has given to the normal rate of increase which would otherwise have taken place in gas consumption. The gas receipts for sales by meter show a net increase over last year of about $8,000; but, on the other hand, the receipts from public lamps have fallen off no less than $35,000 during the same period.

The list of casualties shows only five persons injured during the year by electricity, one of which cases resulted in death. This was an accident resulting from a contact between the primary and secondary wires of a transformer, a possibility which is now most carefully guarded against in the most approved forms of apparatus of this kind.

INSULATED ELECTRIC CONDUCTORS.[1]—IV.

BY

James Brainerd Williams M.D.

CHAPTER III. (*Concluded.*)

LET us next test a wire insulated with a vulcanized rubber compound. We find upon charging it and then touching the insulated layer with the finger that the spot of light suddenly drops four or five divisions, perhaps vibrates a little, and then comes to rest. We place a second, and then a third, finger upon the dielectric and obtain further "drops," but no leakage, the spot of light, after the second and third drops and their accompanying vibrations remaining stationary. These drops are caused by the absorption of small portions of the charge by those portions of the dielectric between the fingers and the wire, and *not* by any leakage. They vary with the extent of surface touched by the bodies connected with the earth—in other words, with the capacities of the condensers thus formed—and with the specific inductive capacity of the material of the dielectric. As the preliminary tests have shown us that this wire is well insulated, we will test it further, and obtain results which are recorded for future reference when comparing this wire with others of the same diameter and length, having the same thickness and length of insulating layer or dielectric. We take eight inches of the wire and trim and paraffine the ends of the dielectric to prevent surface leakage. A strip of smooth tinfoil (the writer generally uses a wet rag) is closely wrapped upon (say) four inches of the dielectric. This converts the four inches of the sample into a condenser, and what we now want to ascertain is the *rate* at which this condenser discharges itself. Lay the sample thus prepared in the **U**-shaped supports, connect it with the electrode of the quadrants, and hang the hook H, upon the tinfoil. Then fasten a *tested* ground wire in the binding screw of the lever K, and depress K until it is held against the bottom contact of the key by the trigger.

---

[1] Seventh Annual Report of the Board of Gas and Electric Light Commissioners of the Commonwealth of Massachusetts. (Pub. Doc. No. 35.) Boston, 1892.

[1] *Copyrighted* 1891, *by James B. Williams, M. D. All rights reserved.*

The quadrants are now fully charged, and we wait until the image rests at 300. A watch is held in one hand and at a given time the finger knob of the trigger is strongly depressed and the lever, K, being thus released, flies past "Insulate" to the top contact of the key. Connection is thus established between the outer coating of the condenser (the tinfoil) and the earth by means of the hook, flexible conductor between the hook and top contact, lever, and ground wire, G, one branch of which is fastened to the binding screw on the rear pillar of the key. The instant the lever strikes against the top contact the spot of light always makes a sudden drop, but its subsequent movements depend upon the specific resistance of the insulating material. If this resistance be high the image will settle upon 290 (say) and remain there. If the resistance be lower than in the last instance the image instead of settling upon 290 (say) will "hesitate" upon it, as it were, for an instant, and then pass slowly down the scale. If the resistance be still lower the image will drop at first, then its speed will become less; but there will be no checking of the speed after this, and the image will move steadily down the scale, but considerably faster than in the second instance. In the second instance we note the time occupied by the image in moving from 290 to 100, for instance; and in the third the time occupied in falling from 300 to zero, for instance. The information we have obtained is written on a tag, with the date of testing, and the tag secured to the sample.

If this sample be tested at the same potential six months afterward we will obtain the same results provided—

1. The normal position of the needle and, consequently, the zero position of the image on the scale have not been changed during the interval. We could not be certain that these changes had *not* occurred if the needle system were suspended by a single fibre and its movements controlled by means of permanent magnets.

2. Dust or moisture, or both, have not been deposited upon the exposed surfaces of the insulating layer, including the paraffine on the ends.

3. The insulating material has undergone no change.

4. The insulation of the apparatus is perfect then, as now.

5. The electrometer, scale, lamp, screen, and lens occupy the same position relative to each other during both tests. Even if removed, the electrometer and scale can always be replaced in the same positions by the aid of the "hole-slot-and-plane" arrangement.

We can always ascertain the time required for the image to fall from 300 to 150, while testing any *well* insulated sample, no matter what the first drop may be or how far the image has passed down the scale after the lever strikes against, and while it remains in contact with, the top contact of the key. This is done by raising the potential of the quadrants while the leakage is going on, by sparks from the coil, until the image is brought back to 300. To prevent the dielectric from being pierced by the sparks during this or any other process of charging, an adjustable device is previously placed between the electrodes of the quadrants which regulates the length of the sparks.

There are other methods by which samples can be tested by the electrometer when charged to high potentials, but those already explained must suffice. If we subject insulated wires now manufactured—omitting those termed "weatherproof"—to potentials of about 3,000 volts, and test them with the electrometer, we find a wide difference in the insulation resistance of their dielectrics. Some will leak rapidly if but four-inch lengths are tested; others will show very little leakage in 12-inch lengths; and others are so highly insulated that several feet must be tested in order to obtain any appreciable leakage. To further illustrate the uses of the apparatus, we fasten a fine wire in the groove of a glass or porcelain insulator, mount it on the pillar on the base of the key—the horizontal arm being removed from the pillar—and connect the fine wire with the electrometer, and charge to about 5,000 volts. We find upon touching *any* portion of the insulator with the finger, and sometimes with the point of a pin, that the charge rapidly escapes. If we carefully clean and dry the insulators *immediately* before testing they will not leak. For further information on this subject the reader is referred to an article by the present writer, on Porcelain and Glass Insulators in THE ELECTRICAL ENGINEER of February 17, 1892.

Leakage at the ends of lead-encased cables, when certain kinds of insulating material are used for the dielectrics, is a subject which deserves more attention than it usually receives. In some cases, marked leakage will occur in a few minutes, if the newly cut ends of such cables are exposed to dampness. This subject will be treated of in an article on the protection of insulated electric conductors.

There are many experiments which can be beautifully illustrated by means of this testing apparatus, such as the variations of the capacity of very small condensers, and the phenomena of the residual charges of the same—the variation of the capacity of a condenser the inner coating of which is a bare wire six inches long, the dielectric being air, can be demonstrated—detecting the presence of deposits of dust and moisture, invisible to the naked eye, on insulating material, the detection of the slightest deterioration of insulating materials, etc., but want of space will not allow of the details of such experiments being given. Another use for which this kind of testing apparatus is pre-eminently adapted is in detecting changes in the insulation resistance of dielectrics formed by saturating fibrous material with paraffine or certain other materials.

A case which often occurs in practice will be selected for illustration. A copper wire is covered with two layers (wraps or braids) of cotton yarn, and the yarn saturated with melted paraffine, heated sufficiently to expel all moisture from the fibre. If a five-inch length of this wire is tested as soon as the paraffine is cold, exactly as we tested the one with the vulcanized dielectric, we obtain excellent results. If we test it again after six to twelve hours—depending upon the humidity of the atmosphere—we find some leakage. This leakage constantantly increases until, after from 36 to 48 hours, the wire is no longer fit to convey currents for high potential. There has been no deterioration of paraffine during this time to account for the change; and if we wish to ascertain the reason for the change we must have recourse to the microscope. The electrometer simply tells us that the change *has* taken place; but the microscope will show us *why*. This subject will be again referred to in a subsequent article.

To return to factory work. The methods of effecting combinations of two or more of the substances experimented upon and tested, depended largely upon the nature of the substances themselves. For example, many of them could best be combined while in a melted state; others, by means of mixing rolls which were heated sufficiently to render the substances plastic; and others, by dissolving them in one or more volatile solvents, and after thoroughly mixing the solutions evaporating the solvent or solvents. The solvents thus used were bisulphide of carbon, purified spirits of turpentine, benzole, naphthas, chloroform, alcohol, and ethers. As examples of compositions formed by the above methods the following, of which rubber is an ingredient, are given :

1. A mixture of rubber, rosin and paraffine. The rubber is first dissolved in the rosin (which requires five hours) at a high temperature, and after the mixture has cooled to about 230° F. the paraffine is added, and the mixture well stirred.

2. A mixture of rubber, shellac and chalk. The rubber is first worked upon the rolls, which must be hot enough to soften the shellac, until it acquires the same temperature as the rolls. The shellac, in a finely powdered condition, is then slowly added to the rubber and the two are thoroughly incorporated. The chalk is added last, and the whole mixed for about 15 minutes.

3. A mixture of rubber and paraffine. The rubber is first dissolved in bisulphide of carbon and the paraffine, in small pieces or shavings, added to the rubber solution and dissolved therein, the solutions being stirred from time to time. After the paraffine is dissolved the solvent is evaporated. The process of dissolving, mixing and evaporating is best conducted in a covered vessel heated by means of a steam jacket and provided with a stirring apparatus. It is understood that suitable proportionate quantities of all of the above-mentioned ingredients should be used; and that the examples are given simply to illustrate methods of effecting combinations, for the same combinations can be, and were, effected in other ways.

To describe in detail all of the ways in which the majority of the substances enumerated in Article I were *used* would alone require several articles. In this connection, the term "used" comprises (1) the methods of combining the substances, (2) the different kinds of dielectrics formed by them, (3) subjecting them to heat, cold and to chemical agents, (4) examining them with the microscope, and (5) testing them electrically and otherwise. The following, however, will give a comprehensive idea of the plan generally followed throughout the investigation: The substances were first cleansed of any foreign matters, and a preliminary test of each made with the electrometer. If its specific resistance compared well with that of a chosen standard, or if it possessed properties which might render it useful in combinations, though it lowered the specific resistance of such combinations, it was reserved for further use, but if otherwise it was rejected.

At least four specimens—often more—of each material or composition were applied to copper wires and one to a sheet of paper about 5 inches square. The ways in which the materials were applied to the wires depended, like those of forming combinations, upon the nature of the materials. For example, some were applied while in a melted state; others by means of a tubing machine; others in strips, either spirally or longitudinally; and others, to fibrous material on the wires, while in solution in volatile solvents, or liquefied by heat. If the materials contained rubber and sulphur they were vulcanized. As soon as the wires were insulated they were tested with the electrometer, and the results of the tests of each dielectric, together with its formula, date of testing and the character designating the material written upon a tag affixed to the wire, and also recorded in a book. Each sheet of paper contained one or two specimens. One consisted of a lump of the material stuck to the paper; the other was made by saturating a portion of the paper with the material, whenever it could be done. The formula of the material, date of application and the number or letter designating the material were written on the paper. These specimens were intended principally for ocular examination.

After the wires were tested, one was kept in a dry place free from dust, the dielectric being exposed; the dielectric of the second was covered with lead or tinfoil, and the ends kept sealed; a third was exposed to various chemicals; and a fourth exposed to the atmosphere in and about the factory. In three to four days after the wires were coated they were again tested, and the results of the tests endorsed upon the tags. Many of the materials tested were found, after a few days or weeks, to be worthless for commercial purposes, for the reason that they would deteriorate, or they absorbed moisture too readily; exclusion from light and air caused them to become viscid, etc., etc.; and yet these same materials had tested well when prepared and applied to wires.

All obtainable wires made by others were tested and compared with each other and with those made by the writer. Whenever comparative tests were made, care was taken to have the wires of the same length and diameter, and the dielectrics of the same length and thickness. A difference in length of ⅛ of an inch would sometimes make a considerable difference in the results of the tests.

The potentials used throughout the investigation were never less than about 3,000 volts, and sometimes above 10,000, and the dielectrics of all the wires, whether those made by the writer or by others, when tested electrically or otherwise, for comparative results, were always subjected to the same conditions, if possible.

The present writer maintains that all dielectrics should be tested with currents of high potential—at least 3,000 volts. When a dielectric is tested with a current of from one to one hundred volts, the common practice, there is no particular stress upon the insulation, and the dielectric may show a very high insulation resistance when so tested. But if the testing current has a potential of 3,000 volts and upwards the case is different; and many dielectrics which test well at low potentials cannot endure the strain produced by the high tension current, but break down.

From what has already been written, the reader can form a good idea of the magnitude of the work accomplished by the writer and its importance, which work, from the begining, was conducted with a view to practical results. In the succeeding articles it will be his endeavor to set forth results obtained by careful and conscientious investigation; and he hopes that the information about to be published will prove of interest not only to the scientific world generally but to many now engaged in the manufacture of insulated conductors; and he has reason to believe that much of this information is entirely new—at least it has never appeared in print previous to the publication of these articles.

NON-ARCING METALS.

BY

Reginald A. Fessenden.

WITH reference to the very interesting paper by Mr. Alex. J. Wurts, it may be apropos to recall the experiments of M. Jamin on arcs between different metals. M. Jamin showed that if an arc be placed in an alternating current circuit, there is no change in the nature of the current which passes, if both points of the arc are of similar material; but if of different materials, one wave of the current is more or less suppressed, and a voltmeter placed in circuit acts as if the current were direct and not alternating.

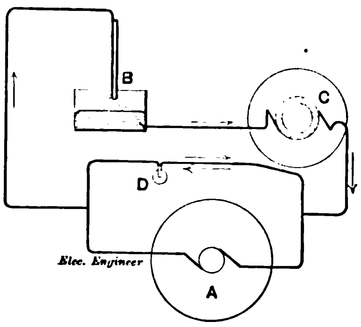
In some experiments made by Mr. John Kelly and myself in 1890-91, it was found that with the mercury-carbon arc (one of the pairs described by Jamin) the suppression of one of the waves was complete and such a circuit, as shown in the accompanying diagram, was found capable of running continuous current motors. It was also used for starting up synchronous motors under load. I am not aware that M. Jamin has put forward any theory to explain this action. But as my own idea of the action which takes place is somewhat different from that of Mr.

Wurts, I subjoin it. Mr. Wurts' theory is that the non-arcing metals have this property by virtue of the arc forming vapors of their oxides, while with the "arcing" metals vapors are formed of the metals themselves, that the vapors of the oxides are non-conductors, and the vapors of the metals are conductors.

While it is true that the vapors of many of the metals are conductors, this is not by any means a universal law. It has been shown by Crookes and others that mercury vapor has a resistance extremely great in comparison with that of air and other gases, and this fact has been used by those who hold that the passage of electricity through gases is due to a kind of electrolysis, as an argument in favor of their theory; for, mercury having only one atom to the molecule in the state of vapor, it is evident that no electrolysis can take place.

It is therefore interesting to find that of the six metals experimented on by Mr. Wurts, the vapor densities of all those which have been determined (*i. e.*, zinc, cadmium and mercury), have only one atom to the molecule in the state of vapor, and that consequently their vapors are probably of very high resistance; in fact, much higher than the vapor of their oxides would be. So we may suppose that the cause of the non-arcing of zinc and the other metals described is due to the insulating properties of the metallic vapors themselves.

There are a few facts which seem to confirm this latter view. First, the suppression of phase by the mercury-carbon arc goes on just the same in an atmosphere of hydrogen as in the air, or, as it has seemed to me, better. Under such conditions, of course, no oxide can be formed. Second, if a mercury-carbon arc be used to run a direct-current separately excited motor, so soon as the arc gets beyond a certain length (in consequence of stoppage of feed, for instance), the motor will stop and run the other way, showing that the other wave has now been stopped out and that the one which was formerly stopped out has taken its place. I have accounted for this by supposing that when the arc gets beyond a certain length, the mercury vapor oxidizes and that the oxide vapor is a better conductor than the carbon vapor. This, however, is not certain; but the fact that I have not been able to obtain the effect in hydrogen gas is in its favor.



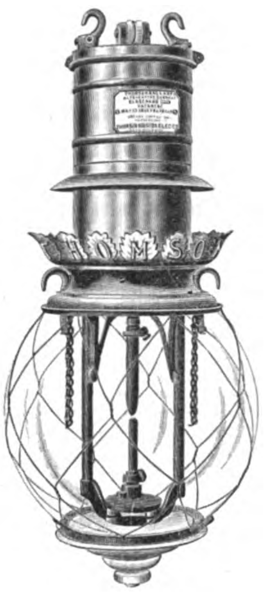
Experiment With Carbon Mercury Arc.

It is possible that a lightning arrester on Mr. Wurts' very ingenious principle might work better with an air gap having its sides of dissimilar materials, as carbon-zinc, so that the lightning discharge could easily pass to ground, but the street railway current could not cross the gap. However, Mr. Wurts is no doubt the best judge of that.

AN ELECTRIC FIRE ENGINE.

The Kummer electric fire engine, made by Messrs. Kummer, of Dresden, uses 50 amperes at 100 volts, or 75 amperes at 65 volts, being 5,000 watts. The pump throws 180 cubic feet of water per second, and with a nozzle of three-quarter inch diameter, gives a height of throw of 100 feet. It weighs 2½ tons, and costs only about half that of an ordinary steam fire engine.

THE THOMSON-HOUSTON "RIBBON-FEED" ARC LAMP.



Thomson-Houston "Ribbon-Feed" Arc Lamp.

A great many efforts—and some of them singularly successful—have been made to shorten the ordinary arc lamp, so that it may be introduced indoors, and be employed where ceilings are low, and where it is naturally desired to keep the lamps beyond the reach of persons whose curiosity is greater than their prudence. It is obvious that the chief difficulty in shortening the lamps arises from the length of the carbon-carrying rod and the fact that the upper mechanism of the lamp must be provided with a tower from which the rod may gradually drop.

In the new "ribbon-feed" lamp just perfected by the Thomson-Houston Electric Company, an important new departure has been made. It will be remembered that in some arc lamps of European production dispensing with the upright tower for the rod, the carbons have been fed inwards on a horizontal plane, while in one instance the lamp was so constructed as to burn curved carbons. The new lamp secures all the advantages of the old form of tower lamp and all the compact symmetry of the others by adopting a metallic ribbon, which occupies practically no space and which, being attached to the upper carbon, allows it to descend in the usual manner, as quickly as consumed. The lamp is but 27½ inches from top to bottom, is only 6 inches wide, and weighs 21 pounds without the globe. The feeding and regulation are extremely good, the arc being always of the same length, perfectly steady, brilliant and free from hissing. The entire mechanism is protected from dust and dirt. The lamp is being made for indoor work on either arc or incandescent circuits. On arc circuits, the lamps are run in series, as usual, and regulate and cut off automatically. On incandescent circuits, they are run in multiple or two in series, a small rheostat or bank of incandescent lamps being used as a controlling device. As will be observed, simple and effective provision has been made for releasing and lowering the globe to clean and recarbon.

DRIVING LOOMS BY ELECTRICITY.

The city council of St. Etienne, France, has decided to apply electric power to all the hand-looms in the city, and contracts have been made with an electric company for the necessary plant. The dynamos are to be driven by water from the city reservoirs. There is practically an unlimited supply of water, with a fall of upwards of 100 ft. The bulk of the enormous output of ribbons ($22,500,000 a year) is the product of house industry. The weavers for the most part own their own looms, and operate them by hand in their own houses. There are 18,000 looms which are thus distributed among the homes of the weavers.

ACCUMULATOR CARS IN ROME.

It is stated that the Omnibus and Tramway Company of Rome has recently made experiments with an accumulator car fitted with motors, batteries, &c., supplied by the Oerlikon Engineering Works. When fully charged, the cells are said to be capable of yielding energy to propel the car 93 miles, so that it is only necessary to recharge every alternate day.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, APRIL 6, 1892. No. 205.

Our country has secured to the common laborer, as no other country has, the fruit of his inventions, and richly has he repaid the provision.—Chauncey Smith.

STUDIES IN INSULATION.

EVERY organization of apparatus for the utilization of electricity for industrial purposes, whether great or small, must in the nature of things comprise four essential elements: First, a means of setting in action, or as it is commonly termed, generating electricity; second, a conductor for conveying the electricity to the point where it is to be utilized; third, insulating media for confining the electricity to the conductor in every part of its course; and fourth, translating apparatus for converting electrical into such other forms of energy as may be required. Whether the electrical energy is to be made available for heat, light, power, chemical decomposition, or the transmission of intelligence, makes no difference, so far as concerns the existence of these primal conditions.

Thanks to the unwearied labors of a vast number of capable investigators, we have during the past twenty-five years gained an extraordinary amount of absolute knowledge respecting some of these conditions. Theory and practice have gone hand in hand, until we have to-day reached results little less than marvelous. The only margin left for improvement in the efficiency of dynamo-electric generators is a beggarly 5 per cent. With electromagnetic apparatus of all kinds for utilizing electric energy, the conditions of maximum efficiency may be said to be equally well understood and practiced. Of the characteristics of the various materials classed as electric conductors, we can expect to learn but little more that will tend to materially increase their efficiency.

In forcible contrast to all this accumulation of knowledge in the other branches of the subject, when we turn to the question of insulating materials and insulation, we are confronted on every side by a vast area of ignorance; it is in fact a territory which may truthfully be said to be almost wholly unexplored. It is certainly strange that this most important, not to say essential department of the field of modern electrical engineering should up to the present time have received so little systematic investigation.

It affords therefore little occasion for surprise, that the series of articles by Dr. Williams, commenced in THE ELECTRICAL ENGINEER of March 16, in which he has undertaken to give the results of his exhaustive and elaborate investigations in this hitherto neglected field of research, should have excited a degree of interest in electrical circles, which to say the least, is quite unusual. The chapters already published evince a broad and comprehensive grasp of the subject on the part of the author commensurate with its practical importance, and this is combined with a minuteness and accuracy of research which even reminds one of the immortal work of Faraday, than which there can be no higher standard.

In the chapters thus far published, Dr. Williams has given quite fully the details of his apparatus, and general methods of investigation. This is to be followed by a separate examination of the different substances employed as insulators, classified in groups, as for instance, gums, resins, vegetable oils, mineral oils, fibres, minerals, etc. The methods of preparing the various non-conducting materials and of applying them to the conductors; an examination of the various modern types of insulated conductors; their relative advantages and disadvantages; the comparative advantages of different protective coatings; the occurrence of faults, latent and otherwise, during the processes of manufacture, and many other equally important matters, will all receive attention. From beginning to end of his investigations, Dr. Williams has kept steadily in view the practical results which may be expected to flow from a thorough knowledge of all the characteristics of insulators and insulating materials, and for this reason alone, wholly aside from the scientific aspect of the question, we are confident that this invaluable series of papers will command the attention of every member of the profession.

INSURANCE OF CENTRAL STATIONS.

ATTENTION was called in these columns last week to the attitude assumed by insurance companies with regard to the use of the electric light, and their attempt to exact higher rates all around, no matter whether the installation was good or bad, was criticised. It seems to us that by such action the companies only encourage bad work, for if careful construction is practically rated with the bad, the inducement to let things go will be rather strong.

But that is only one side of the matter. Central stations are equally the subject of invidious distinction and attack. In proof of this we quote below a letter received by us last week from one of the foremost central station men in the country. He has a superb station, finely built, well equipped and run with the highest engineering ability. Yet none of these qualities availed him, and he has been compelled to meet the insurance agents with a little of their own strategy. He says:

> The very best rate we could get on our station last year was

> $1.80. I placed $200,900 at 80 cents in mutual companies, through the Electric Mutual, and when I was approached this year by the local representatives of the stock companies I told them that we should not consider any insurance proposition from them; that we could find enough mutual companies to carry our business; that I was fully aware of the criticisms they would make on the mutual companies, but did not desire to waste any time discussing them. The result was that the local board took the matter up and made me a rate of 80 cents on my machinery and 65 cents on the building, an even better rate than we got from the mutual companies. The character of our risk entitles us to as good a rate as can be made on any good manufacturing property, but we could not secure this rate, except by these methods. It is needless to say that last year they made every possible effort to convince me and the officers of the company that the mutual companies were valueless. I did not feel a great deal of confidence in some of the companies we were compelled to place our business with, but realizing that we would either have to stand their extortion or take this extra risk, I chose the more independent if not the wiser position.

Evidently this was the best way to deal with the situation, and what one central station manager has thus done, others can do. The difference between $1.80 and 80 cents or 65 cents is too great to be explained on any tenable theory as to the risky nature of the station one year and its safety the next.

SINGLE MOTOR vs. DOUBLE MOTOR EQUIPMENTS.

THE Chicago Electric Club, in its desire to maintain its reputation as an institution fostering lively and timely discussions, has entered into the fruitful domain of electric railroading, and its members are now being treated to a series of papers on the advantages and disadvantages of single and double motor equipments for street cars. At the first session Mr. Elmer A. Sperry, contended for the single motor, and last week Mr. G. K. Wheeler also argued in the same vein. These gentlemen were followed by Prof. S. H. Short who advocated the use of the gearless motor. While the zeal of these gentlemen is to be encouraged, it cannot be denied that the conditions both as to location and management of electric roads vary to such an extent that it would be almost impossible to lay down any hard and fast rules as to the application of any particular type of motor. Besides, street railway companies not infrequently allow the question of price to enter largely into their acceptance of apparatus, so that many arguments, otherwise valid, are ignored. Still, healthy and impartial discussion is always to be encouraged, and the Chicago Electric Club is thus adding to its usefulness.

DIRECT CURRENT TRANSFORMATION.

THE advocates of the continuous current have always maintained as a standard proposition in their arguments that while continuous conversion was theoretically possible its practical realization involved such difficulties and complications as to make the system prohibitory for general use. Not the least weight was given to the fact that continuous current transformation required moving machinery, which necessarily demanded constant supervision, whereas the alternating current transformer demanded no attention whatever. But examples of successful continuous current transformation are constantly increasing in number, and an installation, at Olympia, Washington, which we describe in another page, will show to what extent the method is applicable in practice. In the present state of the art it is true that such transformation demands the employment of moving parts, but who shall say that the future may not produce a continuous current transformer involving nothing beyond molecular movement of its parts?

SUBWAYS FOR WASHINGTON.

A FEW months ago we had the pleasure of printing a very full abstract of the report of the Electrical Commission appointed to consider the question of subways for the District of Columbia. The report has now been printed in full as a Government document, and makes a portly volume, being, as we said at the time, a most valuable and important contribution to the literature of the subject. It presents a very complete survey of work done in Europe and this country, and in the main arrives at conclusions that must be accepted. Its recommendation of the Lynch-Lake terra cotta-conduit is no more than might be expected, in view of the excellent results already obtained with that type of subway in Washington, with all classes of service; and we presume that the plans of the Commission will now be carried out, as laid down in the report and in an elaborate series of maps of the District.

GROWTH OF THE TELEPHONE INDUSTRY.

THE figures given elsewhere in this issue from the annual report of the American Bell Telephone Co., are eloquent as to the steady growth of the telephone industry in America, and as to the profitableness of the business so far as the parent organization is concerned. The first of the fundamental patents has another year to run, and then we may expect to see outside manufacturers coming in to make hand telephones for a variety of uses; but the work of operating exchanges seems likely to remain under existing control for a long time. It is practically from this latter source that the whole of the parent company's income is derived under perpetual contracts, so that even with great activity in the hand telephone field, the companies would not suffer any diminution of value or revenues. That there will be competing exchange service by and by, is beyond doubt, but the strength of the present network of Bell local exchanges and long-distance lines, with local franchises, subways and rights of way, and with solid cash reserves to draw on, may prove equal to the severe test it will get.

Celluloid Storage Batteries.

WE bring before our readers in this issue a new type of storage cell, in which the inventor has sought to decrease the weight and to otherwise avoid the difficulties encountered in lead storage batteries. The employment of celluloid for this purpose in the manner described is quite novel, and if the claims made for the cell are proved in actual practice there ought to be room for this type in many situations, not the least important of which would be that of storage battery traction.

A New Duplex Telegraph.

IMPROVEMENTS in the systems of telegraph at present in vogue are so rare that an advance in this field calls for notice. As such the new duplex telegraph system of Mr. J. J. Ghegan, described in another column, will prove of interest, owing to the fact that it may be said to be both a duplex and a diplex in its nature, and thus to overcome the drawbacks attached to either of these considered alone.

HIGH-PRESSURE STEAM IN CENTRAL STATION WORK.

BY

C. Zehme.

Referring to the article on the above subject in The Electrical Engineer of January 20, I beg to submit the following remarks:

This article mentions among other things that a number of well-known European engineers maintain that condensing steam engines are no longer economical, when pressures as high as 160 or 180 lbs. per square inch are employed. I am astonished that by employing steam of this pressure the economy of condensation can be doubted at all, and I do not think that any German engineers are of this opinion.

A triple-expansion condensing engine, working with steam at a pressure of 170 lbs., and with the most economical cut-off, works with an economy greater, at least by 20 or 25 per cent., than a triple-expansion non-condensing engine. This is, of course, more than enough to cover in the course of a few years the expenses of a condensing apparatus, which consists of a jet condenser connected with the main engine and driven by it. The length of time required to recover this additional outlay depends on the quality and cost of the condensing apparatus, on the price of coal and water, and, with central stations for electric lighting especially, on the length of time the engine runs during the year.

But the greatest importance is to be attached to the cost of the condenser and to the working period of the engine. The time for recovering the cost is longer, when a surface condenser is employed or some independent condensing plant driven by a small independent engine. It appears that the use of such independent single or central condensing plants, especially with surface condensers, has lately come much in vogue abroad; the advantages claimed for them, however, are very doubtful, and only the surface condenser ought to be employed where the water is bad. With regard to the working period it is to be remarked that, when it is long, for instance with electric power transmission, electric railways and with central stations for electric lighting which are furnished with storage batteries, condensing is always very economical, even when pressures as high as 180 or 250 lbs. are employed.

Regarding the triple-expansion engine, mentioned above, it would be necessary, when taking away the condensation, to increase the pressure of the steam 70 or 80 lbs, in order to obtain the same coal consumption. But then we have increased expenses; first, with the engine which must be constructed as a quadruple-expansion; secondly, with the boilers, and thirdly, with the steam pipes. For this money a jet condenser could be paid for twice over.

As to German engineers, they are, I dare say, all of the opinion that with triple-expansion engines working with steam of pressures of 160 or 180 lbs. to the square inch, condensing will lead to considerable economy in working. With all central stations in Germany and with those of neighboring countries, built by German engineers, it has been, and it is, always the principal care, that the central station is near the water, and even where it is impossible to build it there, and where sufficient water cannot be obtained the employment of condensing is not given up. Either the water is brought from distant places or some apparatus is employed for quickly cooling the hot water of the condenser, in order to use it over and over again. Such an apparatus, for instance, exhibited at the Frankfort Electrical Exhibition by Mr. Klein, consists of a wooden-stepped tower, in which the hot water is made to trickle down over a system of parallel boards, while an upward current of air is maintained by means of a ventilator. Such cooling towers have been carried out on a very large scale in many steam plants; for instance, in a large central station for electric lighting in combination with the jet condensers of triple-expansion engines, constructed by Mr. F. Schichau of Elbing, in Prussia; and the results obtained with it have been found to be very satisfactory, in spite of the great cost. The quantity of fresh water added to the circulating water is very small, approximately as large as the consumption of steam.

I do not know any central station in Germany with triple-expansion non-condensing engines, and it will interest you to hear that, because in another part of the same issue of The Electrical Engineer it is mentioned that probably more than nine-tenths of the present existing American stations are so situated that the operation of condensing engines is impracticable.

Finally, I must not omit to remark, that the working with triple-expansion non-condensing engines in central stations without storage batteries may sometimes give rise to a great deal of trouble. If the load is so light that the expansion to the atmospheric pressure takes place as early as the intermediate, or even in the high-pressure cylinder, the engine works very uneconomically and noisily, especially when running at a high speed, and that is still more to be feared with quadruple-expansion non-condensing engines.

Nürnberg, Bavaria.

THE ECONOMY OF CONDENSING WITH TRIPLE-EXPANSION ENGINES.

BY

J. Van Vleck

I have read with interest the above article from your Nuremberg correspondent Mr. Zehme in regard to the matter of condensing with triple-expansion engines, from which it appears that the writer does not doubt the efficiency of condensing under all conditions. I note that he states, in effect, that with a triple engine, and a pressure of 170 lbs., the condenser adds from 20 to 25 per cent. to the engine efficiency, which saving, he thinks, would in a few years cover the expense of operating the condensing plant.

I find it impossible, however, to check these figures, and I do not wholly agree to his conclusion. As a result of my study of cards taken from triple engines, I can only admit, that with pressures of 170 lbs., and above, the work done by the condenser is not much in excess of 15 per cent. of the work done by the live steam, and that when the energy is deducted which operates the air and circulating condensing pumps, there is but 10 or 12 per cent. additional gain. This increase of power and of efficiency may easily be offset by the interest on the cost of the condensing plant together with its depreciation and cost of maintenance.

I have not the time to enter into a more complete explanation of this matter, but should any one take the trouble to plot out (on the same scale) the cards taken from a well-proportioned triple engine, they will be surprised to observe the small percentage of work done by the condenser, from which, as before stated, should be deducted the work required to operate the condenser pumps. With 200 lbs., and over, the strip of work on the card, done by the vacuum, is very narrow indeed, and one almost doubts the advantage of condensing at all.

I believe, however that triple engines should be supplied with condensing apparatus wherever it pays to do so; but this is a nice question to be determined for each specific case. In many instances, for example, it may be impractical or too expensive to obtain sufficient water for condensing purposes; or else, it may be difficult to lead away the outflowing hot water from the station. Then again, if the station should purposely be located near a body of water and away from the electrical centre of distribution, the extra expense for copper conductors may more than counterbalance the advantages of having a condensing plant.

No general rule can determine whether, or not, to employ condensers, as each case has to be considered by itself; the question being one of financial reckoning, rather than of engineering. But the fact that many conditions do not permit of the economical use of condensers should not prevent central stations from reaping the advantages to be gained by employing triple-expansion engines, which with high steam pressure should give magnificent economy. A triple engine is futhermore usually constructed as a three-crank engine which gives a much more even rotation than a two-crank or compound engine—a very desirable feature when "multipolars" are attached.

If, however, a triple engine is to run non-condensing, it should be designed and proportioned accordingly, which is a fact that our German friend may have overlooked. For instance, the non-condensing triple engine now running at the 26th street station of New York Edison Company is proportioned and controlled so that a steam pressure of from 15 to 22 pounds is maintained in the low pressure receiver; whereas, if it were designed as a condensing engine this pressure might seldom exceed 5 or 6 pounds.

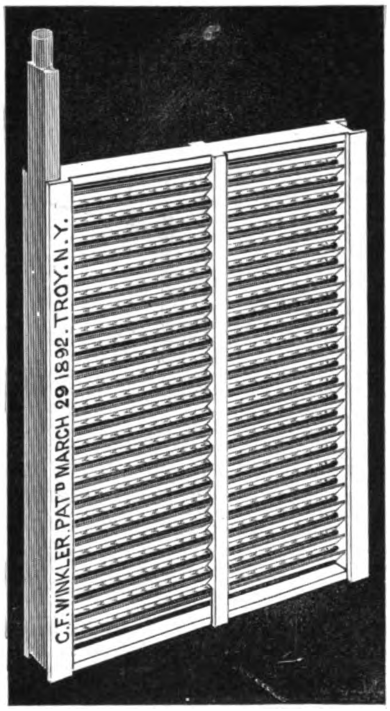
In this connection it is interesting to note that there is now running at the City Roller Mills, at Limerick, Ireland, a large quadruple-expansion engine that was designed for, and is operated, non-condensing, which remarkable engine, it is claimed, delivers a horse power with an expenditure of 1.6 pound of coal, the steam pressure in this case being 185 pounds.

It is true that central stations having variable loads, or having a few generators, should not employ non condensing triple engines, unless storage batteries form a part of their system. Different conditions demand different types of engines. In some cases single-cylinder engines are the proper things; other requirements call for compound engines, while again, other cases demand triple engines. But as to condensing, that should, or should not, be applied, depending on whether it will pay or not. With plenty of water for condensing, and with heavy and constant loads, quadruple engines will undoubtedly fill their place.

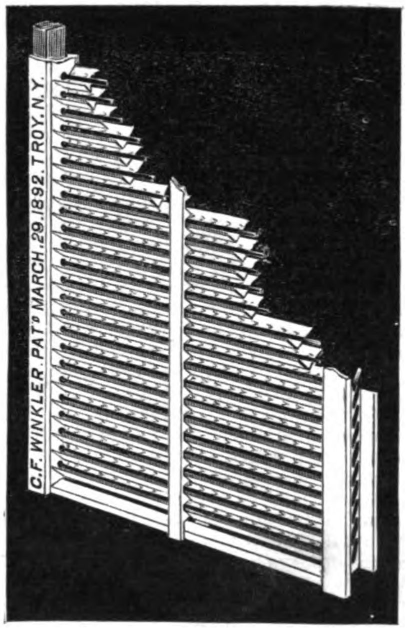
I further note in the communication of Mr. Zehme, that in Germany, when water is scarce, the hot condensing water from the engine is sometimes cooled by allowing it to trickle down through a tank through which air is blown. Now, practices similar to that have been tried in this, and other countries, but all such bulky affairs will perhaps never come into prominence in these days of high steam pressures; although I have no doubt that such a contrivance might add greatly to the efficiency of an old-fashioned plant operated by low steam pressure and with single or compound engines.

THE WINKLER CELLULOID STORAGE BATTERY.

SOME months ago we made note of the fact that Mr. Ch. F. Winkler, of Troy, N. Y., was engaged in perfecting a storage cell which was designed to overcome the difficulties heretofore encountered with lead storage batteries, and at the same time effect a large reduction in weight.



C.F. WINKLER. PAT^D MARCH 29 1892. TROY. N. Y.



C.F. WINKLER. PAT^D MARCH 29.1892. TROY. N. Y.

FIGS. 1 AND 2.—THE WINKLER CELLULOID STORAGE BATTERY.

The Winkler element as now constructed is illustrated in Fig. 1, complete and Fig. 2 shows it in part section. The element consists of a series of celluloid troughs in a frame of the same material. Each trough contains a metallic conducting wire embedded in active material, the wires from the several troughs in each plate being connected to a solid conductor which forms an electrode. The open space between the bottom of each trough and the active material of the trough below facilitates the circulation of the electrolyte and the escape of gases from the active material is made easy by the V-shape of the troughs.

The method of filling the troughs is a simple process, consisting in simply dipping the plates in a pulp-like mixture of the proper oxide of such a consistency that it will run into the troughs and fill the same, any excess being brushed off after drying. A number of plates constitute a cell in the usual manner, and on account of freedom from buckling and the circulation permitted, an even number of plates may be employed.

The electrolyte employed is the usual one or, for greater portability, a non-decomposable electrolytic jelly may be used.

By the construction adopted Mr. Winkler claims that abnormal currents may be discharged without injury to the plates, being only limited by the heating effect on the lugs, and that after an abnormal discharge the battery recuperates very rapidly.

The expansion of the active material, being unopposed, brings no strain upon the plates and as a consequence there is no tendency to buckling or distortion, while the supporting plates, not being acted upon in charging and discharging, do not suffer deterioration in course of time, like lead plates. Owing to the above two facts the size of the plates is not limited, with the consequence that space can be better utilized, the connections made simpler, and the weight reduced from 40 to 50 per cent. The current in charging being equally distributed and confined to the active material alone and not largely to the supporting plate, as is the case with lead batteries, it is claimed that a greater capacity is gotten for a given weight and surface of active material.

It is also claimed that there is no local action between the active material and plates and the cell will therefore retain its charge indefinitely, being very unlike the lead plate in this respect, and that, unlike the plugs in perforated lead plates, the active material cannot easily fall out, and the plates cannot be short-circuited by conducting matter lodging between them. The internal resistance of the celluloid battery is also said not to exceed that of a lead plate.

NOTE ON THE MOLECULAR MOVEMENT IN A CONDUCTOR.[1]

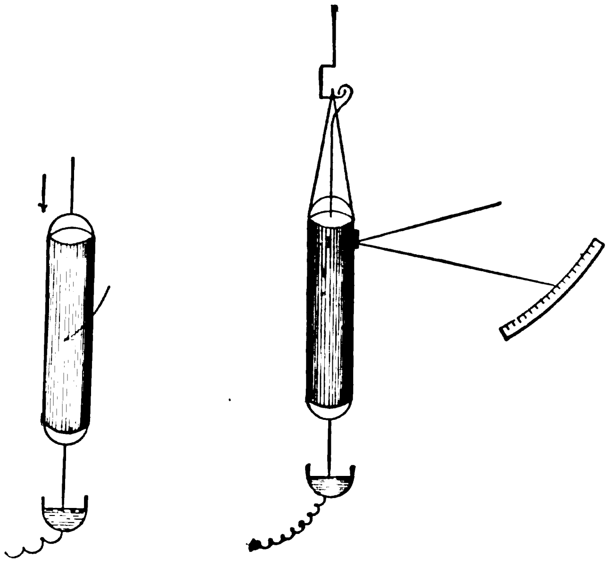
BY PROF. A. E. DOLBEAR.

MAXWELL and others have made experiments to discover whether there was any evidence of momentum in a conductor carrying an electric current. So far as I know all the experimenters looked for a *longitudinal* momentum, that is, one in the direction of the current in the conductor, but no evidence appears to have been discovered that the molecules are thus moved. Still it is as near certain as anything can be and not be demonstrated, that the molecules in a conductor are moved in some way by an electric current. If they be thus moved then there must be momentum in some direction. If it be not longitudinal it may be transverse. If there should be movement in the transvere direction, what kind of experiments would be needed to show it? This is the way the question presented itself to me. When a current is sent through an *iron* wire the latter is twisted, to the right or the left according to the direction of the current. This is interpreted as due to the specific magnetic quality of the conductor, for it does not occur in a copper or other conductor.

Suppose the molecules of a conductor to be *rotated*, each upon its own axis, the axis being longitudinal with the wire, what evidence of such motion would be externally exhibited by the conductor as a whole? Evidently it would be masked altogether in a common wire, for the momentum of any one molecule in one direction would be just balanced by that of the contiguous one in the opposite direction—a condition of things mechanically propagated through the diameter of the wire. In order to discover it, it would be necessary to prevent such mechanical transference of the movement, and this can be done by making the conductor a hollow cylinder. I therefore made a cylinder of gilt paper about 20 inches long and four inches in diameter; this I provided at each end with a bail for suspension, the suspending wire being eight or ten feet long, the lower end of a short wire dipping into a mercury cup as shown (Fig. 1). With this arrangement a decided evidence of twist could be noticed, but on account of the resistance of the gilt paper, a strong current could not be used without so high a voltage, that the paper took fire several times. I then had a thin copper cylinder made of nearly the same dimensions and suspended in a similar manner, and could use a current of thirty or forty amperes. The rotary motions were in the same directions as before, namely—when the current was going down, the twist was always right handed as indicated by the arrow, and of course opposite when the current was reversed.

While there was no doubt about the rotary movement, the weight of the apparatus was so great I concluded to see if one made of lighter material—aluminum, would not give greater amplitude with the same current. A similar cylinder of aluminum foil was prepared and so hung that all tangential movement would be due solely to itself and not at all to any other part of the apparatus, that is, it was mounted with bi-filar suspension. The weight of the foil with its connections were 1.85 oz. (55.6 grams). A bit of mirror was fastened to the upper end, and a beam of sunlight reflected from it upon a scale 16 feet distant, and 25 feet long (Fig. 2).

With this arrangement, the twist produced by the current was such that it was not difficult, by timing the swings and changing the direction of the current, to make the cylinder swing through 90°. A current of 15 amperes swung it through a foot and a half of the scale. It would come to rest at about half the distance of the greatest amplitude of the swing, for each different current employed, and *therefore showed the continuous action of the torsional force for a constant current.* If this be the interpretation of the phenomenon, then the molecules are rotating when there is a constant current, and thus the explanation of the heating effect of the current, is brought back to dynamical and mechanical principles. Adjacent molecules must be rotating in opposite directions at their point of contact, but this vibrating or heat motion necessitates more or less separation, when such rotation goes on; on impact it is arrested so there must be impact and slip, impact and slip, the arrest of motion being the immediate antecedent of the heat, as is friction in any case. These experiments have not been carried out quantitatively for lack of facilities. May be the interpretation is wrong, and some wise one who knows all about it can point out its inadequacy. I think the experiments are new, and may lead to an understanding of what goes on in a conductor when a current of electricity traverses it, if this be not the whole of it.



FIGS. 1 AND 2.

DISCUSSION.

In the discussion MR. MAILLOUX thought the action due to the effect of the current on the earth's magnetism.

MR. TOWNSEND WOLCOTT thought that Mr. Mailloux's remarks would hardly apply to continuous rotation, as such rotation would not take place if the tube were perfectly straight and uniform in resistance.

MR. KENNELLY pointed out that if the cylinder will revolve, any number of other cylinders, inside of, and concentric with it, will also revolve, and this being the case, thought that a solid rod should act in a similar manner under the same conditions.

DR. PUPIN called attention to an experiment of Prof. Braun, of the University of Tubingen[2] in which he found that magnetizable wires twisted in opposite directions, generated opposite E. M. F.'s. He said that Prof. Rowland had called his attention to a current interrupter constructed on that principle, and he thought that the phenomena observed by Prof. Dolbear might be due to a similar cause.

MR. HAROLD BINNEY thought that rotation might be produced by the effect of the bails, as more current would go to one bail than to the other, owing to its tendency to lateral shifting in the magnetic field. This theory was not based upon the supposition that there existed a lack of symmetry in the apparatus. See Fig. 3.

THE CHAIRMAN (VICE-PRESIDENT CROCKER) thought that there would be some lack of symmetry which would cause rotation, and that, if perfectly symmetrical, there would be no tendency to rotate.

---

[1] Read before the American Institute of Electrical Engineers, New York, February 16, 1892.

[2] Braun, F., Deformationsstraume, Wied. Ann. vol. 37, pages 97, 107; vol. 38, page 53; vol. 39, page 130.

Mr. Mailloux called attention to Hall's phenomenon showing that, in a wire or cylinder placed like this one in the earth's magnetism, the current is not equally distributed. This, he thought, might partially explain the peculiar actions observed.

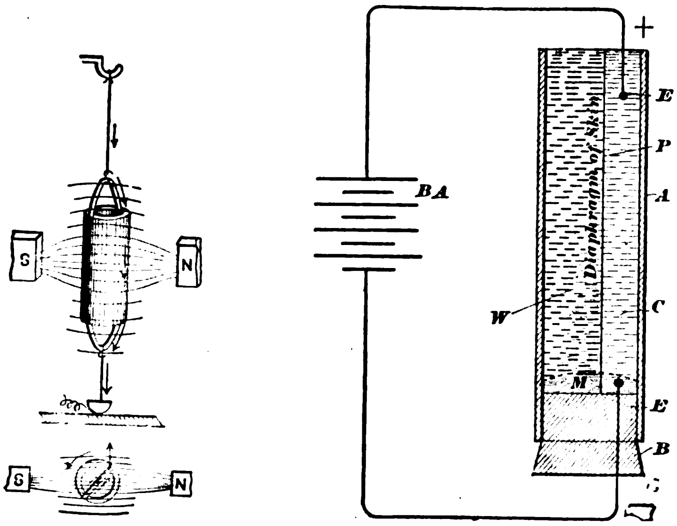
Mr. Wolcott thought the whole effect too small to be noticed there.

Dr. Samuel Sheldon stated that Prof. Hall had used 40 or 50 amperes passing through a Ruhmkorff magnet and a Thomson reflecting galvanometer, with which he observed a very small deflection.

Mr. Carl Hering thought that interesting results might be obtained by shielding the conducting cylinder by a fixed iron cylinder.

The Chairman thought the experiment only suggestive and not conclusive, and that it would have to be carried much further before it could be accepted as a phenomenon of nature.

Mr. Chas. J. Kintner suggested the modified form of apparatus, shown in Fig. 4, and thought that if there were any tendency to molecular movement there, the colored liquid would be forced to rotate through the diaphragm and mix with the transparent liquid on the other side.



Figs. 3 and 4.

c, colored liquid. w, transparent liquid. a, glass tube. b, cork or plug. e e, electrodes. p, porous diaphragm. m, mercury. b a, battery.

The meeting then adjourned.

THE SINGLE-REDUCTION MOTOR.[1]

BY GEORGE K. WHEELER.

It is my opinion that much better results are obtained by a two-pole single-reduction motor than by the four-pole, for the reason that it is much lighter, simpler in construction, has a smaller commutator, half the number of bobbins on armature, also half the number of brushes, and is much more economical to maintain. One of the leading electric manufacturers has produced a motor that I think meets all the requirements for ordinary street railway service; this motor is 15 h. p., weighs about 2,000 pounds complete, including gear, pinion and gear case.

The tendency of modern improvement in railway motors is to diminish the gearing, and I do not think that anything is to be gained over the double-reduction motor by placing two sets of gears and pinions one on each side of a single-reduction motor, as it not only increases the friction losses, but adds an additional weight to the motor, and if the motor frame and armature shaft are properly constructed there is no liability of straining or breaking either by reason of placing the gear and pinion on one side only. It is stated by a number of competent electrical engineers that the placing of one motor on a truck is ample for all ordinary street car service. By experience I have found that with a truck having but one motor attached to one axle, the wheels on the axle to which the motor is attached do not brake as quickly as the free wheels and flats are thus formed on the free wheels on this account; also that it is a difficult matter to ascend grades over three per cent. and that it is next to an impossibility to operate a car so equipped, during the winter months. It is also advocated that the proper method is to gear a single motor to both axles; this in my opinion is open to serious objections. In gearing a single motor to two axles of a truck, it is almost impossible to keep the wheels perfectly true.

It is for these reasons that I believe the best results are obtainable by connecting a single motor to each axle of a truck. It may be argued that there is twice the liability for trouble where two motors are used, but experience proves that this is not exactly so, for by this method you obtain the proper traction and benefit of all wheels, and in case of extra load you have ample power to operate the car under all conditions of service, and in case of injury to any part of one motor, it can be disconnected and the car operated until an opportunity offers to make the necessary repairs.

A single-reduction motor should be so constructed as to give the greatest possible distance between the bottom of motor and top of rail. With the best form of motors which have up to the present time been constructed, the greatest distance obtainable between a 15 h. p. motor and top of rail is 4½ inches when placed on a wheel 30 inches in diameter. I strongly recommend the use of larger wheels, either 33 or 36 inches in diameter. With a motor mounted on 36-inch wheels this will give a clearance of 7½ inches, which is more than ample to clear ordinary track obstructions; and if the motor is thoroughly protected in its frame, it will not be necessary to use motor pans, which have been a necessary evil in connection with double-reduction motors. It may be argued that a car equipped with 36-inch wheels requires an excessive amount of current to operate, but this is not a fact. On a test which I made more than a year ago on a car equipped with 36 inch wheels and a car equipped with 30-inch wheels, the same motor equipment and car of same length and weight, operated over the same length of road on the same day and by the same man, total length of line being 16 miles, it was found that the car equipped with 36-inch wheels required about ¾ of a horse power more on an average than the car equipped with 30-inch wheels, although the 36-inch wheel car required more current in starting and climbing grades; but it would run longer on the level by momentum, and thus average up the current consumption. With the present form of single-reduction motors I think that the 33-inch wheel is of ample size.

On tests which have been made with the best types of single-reduction motors, they have been found to be from 8 to 10 per cent. more efficient than the double reduction, and are capable of attaining a much higher speed under various conditions of service. On a recent test which I made on an over-country road, being some 11½ miles in length, the car was 34 feet in length, and with 25 passengers, total weight of car was 23,700 pounds; the car was equipped with double trucks having two 25 h. p. single-reduction motors to each car. The maximum speed attained was 32 miles per hour, climbing grades of 4 and 5 per cent. at the rate of 17 miles per hour. On a car 16 feet in length, equipped with one 15 h. p. single-reduction motor, the maximum speed attained was 25 miles per hour on a level, and the car in climbing grades of 4 and 5 per cent. would not attain a speed of over five miles per hour.

THE BEHAVIOR OF INSULATING MATERIALS UNDER THE ACTION OF HIGH POTENTIAL DIFFERENCES.[1]

BY H. BLECKLY BOURNE AND W. FOX BOURNE.

Electrical engineers have recently been devoting a great deal of attention to the transmission of energy by small currents at high pressures; and it is clearly advantageous to increase the potential difference until the expense of insulating the apparatus neutralizes the saving in copper. The question of insulation is, of course, the main difficulty, for as we increase the p. d. many substances which are ordinarily considered insulators have to be regarded as fairly good conductors. Numerous experiments were shown to illustrate this point, the current being obtained from a "Hedgehog" transformer capable of developing about 25 h. p. at 100,000 volts, which had been lent for the occasion by Messrs. Swinburne & Co.

The question of sparking distance in air does not seem to be of any great practical importance, but as it has recently been referred to, the following figures, obtained at Messrs. Swinburne & Co.'s works, may be of interest:

Sparking Distances between Needle Points.

P. D. in volts.	Sparking distance in inches.
3,000	0.11
14,900	0.5
24,000	1.0
39,000	1.6
50,000	2.2
62,000	2.8
74,000	3.5
92,000	4.5
97,000	5.0

---

[1] Abstract of a paper read before the Chicago Electric Club.

[1] Abstract of a paper read on March 11, before the Old Students' Association of the City and Guilds of London Institute, at the Central Institution, South Kensington.

Sparking Distances between Plates 2⅛ Inches in Diameter.

P. D. in volts.	Sparking distance in inches.
18,000	0.16
20,000	0.40
44,000	1. 0
70,000	2. 0
90,000	3. 0
105,000	4. 0

The above results were obtained on a cold, dry day, but can only be regarded as approximate, as the distance was found to vary a good deal with atmospheric and other conditions, so that concordant results could not always be obtained on different days. By striking an arc between electrodes of tin wire, which gradually melted, a flame of considerable length was exhibited, and it was pointed out that the length to which an arc could be drawn depends very largely on the current strength available.

It was next shown that, for overhead work at very high pressures, even oil insulators of the best design are quite useless. Wires from the transformer were connected to the stalk and grooves of an insulator which had been dried and filled with clean resin oil; brush discharges immediately occurred over the surface of the porcelain, and when a P. D. of 600,000 volts was reached a spark jumped from the wire to the stalk. Two wires were placed near the ends of a piece of slate about a yard long, and sparks passed freely from the wires to the slate; and a sort of arc lamp was arranged with slate pencils for electrodes. A similar conducting power was shown to be possessed by vulcanized fibre and asbestos mill board. The discharge does not break down or perforate these substances; they behave exactly like conductors. A curious effect was shown with a long piece of slightly damp wood, numerous small arcs being formed, which finally ignited the wood.

The experiment with the oil insulator, and other experiments shown, point to the fact that surfaces of insulating materials, unless absolutely clean and dry, have considerable conducting power. A discharge may sometimes take place on the surface of a non-conductor across a distance much greater than the striking distance in air, and once a discharge has started an arc is formed. A cable insulated with a layer of rubber a foot thick might be useless for 50 or 100 thousand volts, if it had even a small crack. This creeping discharge was also shown by the now familiar experiment in which a pair of discs are separated by a large sheet of glass. In one of the experiments shown, the glass did not break, though the discharge passed through it; and it was found that if there ever had been a perforation, the heat of the arc had fused the glass and entirely sealed up the hole.

The potential difference required to break down or perforate insulators is quite a different matter from the discharge over their surfaces. A number of samples of broken-down insulators were exhibited; they were materials which had been tried for use in condensers, and were in the form of thin sheets of mica, celluloid, or paper impregnated with various resins and waxes, etc., and were about six mils thick; they had been perforated with potential differences varying from 2,000 to 6,000 volts. A piece of cable insulated with a layer of vulcanized rubber of the best quality, rather over one-eighth of an inch thick, was shown; it had withstood 50,000 volts for 25 minutes. In such cases the time element is of great importance, and the dielectric is usually found to become very hot before it breaks down. This fact indicates a very important difference between the effects of direct and alternating currents on insulators.

Whenever, as in the case of a concentric cable, the two conductors are at all close together, we have a condenser which is being rapidly charged and discharged. Now in the case of most solid dielectrics there is a good deal of soaking in, and consequent loss of energy, which manifests itself as heat. This was made very evident in the case of a condenser which was tried at Messrs. Swinburne's works. This condenser was made of sheets of tinfoil insulated with paper soaked in paraffine wax in the usual way; its insulation, measured with a steady E. M. F. of 240 volts, was about six megohms; and the active surface of plates was 5,000 square inches. When it was connected across a 2,000-volt circuit, it was found to absorb more than a horse power, so that a considerable rise of temperature was not surprising. But it was also noticed that its capacity rapidly diminished, and finally disappeared, which was, on investigation, found to be owing to the fact that the foil had melted and so become disconnected from the circuit. Another condenser, made with glass plates one-tenth inch thick, broke down with 2,000 volts after about five minutes, apparently owing to internal cracks caused by the heat evolved. In the case of the sample of rubber-covered wire above referred to, the compound in which the braiding had been soaked melted in five minutes and the rubber became quite softened by the heat in about 15 minutes. This heating effect is much less in the case of most fluid insulators, but seems to be more important in oils having a high specific inductive capacity.

Experiments were then arranged to show some actions of oils under high voltages. A plate was immersed in castor oil, and a point supported a short distance above the surface. On switching on the transformer, a distinct depression was produced on the surface of the liquid. Two plates were then arranged, one over the other, separated by a layer of castor oil on which was floated some paraffine. When the plates had a difference of potential of 20,000 or 30,000 volts, the castor oil rose in a sort of hill, owing to the fact that its specific inductive capacity is higher than that of paraffine, so that by its movement the capacity of the arrangement is increased. It was also shown that particles of sawdust in resin oil were formed into chains, producing a discharge across a considerable distance.

The experiments were concluded by sending the current from the transformer through a number of vacuum tubes. These were of course brilliantly illuminated, but the current was not maintained for more than a few seconds, as an intense heating of the glass and electrodes ensues, which usually breaks the tubes. This fact renders it difficult to measure the power absorbed, but it was estimated from the primary current and voltage that a comparatively small tube may easily be made to absorb 2.5 h. p. while giving a light of only a few candle power.

In the above-described experiments the potential differences were measured by a direct-reading electrometer loaned by Messrs. Swinburne & Co. This and the transformer are intended to be used for experiments to be shown by that firm at the Crystal Palace Exhibition.

BEGINNING ELECTRIC RAILWAY WORK IN BROOKLYN.

WITH regard to the coming electric railway work in Brooklyn, the *Eagle* says:—"The officers of the Brooklyn City Railroad are anticipating the greatest activity. 'We will have to hustle,' said President Daniel F. Lewis. "The first thing we shall do, and we will commence work instantly, will be to enlarge the present temporary power house on Second avenue and Fifth street, so that it shall have a capacity of 1,600 h. p., instead of the present 800. We shall build additional cars and by Decoration Day we expect to be running an increased service on the Second avenue line, to replace the steam motors on Third avenue, from Twenty-fifth street to Fort Hamilton, and to operate the Hamilton avenue line from Twenty-fifth street to Hamilton ferry. To do this we shall have to work with the utmost rapidity and shall, in fact, give out our contracts very soon.

"The next step," Mr. Lewis continued, "will be to complete the equipment of the southern division and to commence work on the central division, possibly at the same time tapping a part of the crosstown division. To do this we shall build a large permanent power station on the water front we now own at the foot of Fifty-second street. This, when completed, will have a capacity of perhaps 5,000 h. p., certainly not less than than 4,000 h. p. This will run the cars of the Third avenue, the Court street and the Furman street lines which, with the others I named previously, form the southern division. It will also supply the power to a part of the central division. The Myrtle avenue, the Greenpoint, the Graham avenue and the Crosstown will probably be supplied with a current from a power house which may be built near Fulton ferry. We haven't completed the details yet, nor decided exactly what we will do with the eastern district lines. We will have to have another power house over there in some central location and on the water front. You see, a water front is almost a necessity for all these stations, as it greatly facilitates and cheapens the transportation of coal and the removal of ashes."

"How long will this take, Mr. Lewis?" asked the reporter.

"I should judge," he answered, "about two years, but, as I said, we will have to hustle."

"What will the cost be?"

"About $6,000,000, I should judge. We haven't perfected the financial arrangements yet. As you know, we have $3,000,000 in bonds in our treasury which we can issue at any time. Whether we shall issue these or more stock we have not decided. We estimate that we can use half the cars that are now being run, and this will save us much money. The rest will have to be sold at a loss. We probably will lose little or nothing on the horses, as we can gradually use them up. You see, a horse lasts about four or five years. In the two years or longer before the trolley can be entirely introduced we can use up all or nearly all our horses. The tracks will have to be largely replaced, or at least strengthened."

Mr. Lewis further said that he was perfectly satisfied with the ten-mile-an-hour speed limitation and with the amount of bonds required for the protection of the city against accident.

President William Richardson of the Atlantic Avenue Company was asked when he should begin preparations for the introduction of the trolley system on his lines and replied:

"We hope to have the line from South ferry to Greenwood cemetery running by June. We shall introduce electricity on the line first as an illustration of the workings of the system, and it will be put on other lines thereafter, first on those lines where the property owners show the greatest anxiety for it.'

SOME RECENT TELEPHONE SUBWAY WORK.

BY J. P. M'QUAIDE.

The construction of telephone subways has always been considered by municipal authorities as a matter of only small expense to those companies contemplating such work. Due credit has never been given to the different companies for the enormous outlay of time and money that is necessary to construct a proper and perfect subway. In the city of Boston many trenches were dug and many manholes are built in places where at high tide there is three feet of water in the manhole. The expense of keeping the subway dry can hardly be estimated.

In Haymarket Square, Boston, one trench 136 feet long 4 feet wide and 7 feet deep required three weeks to dig on account of water and gas mains to be moved, sewers to be cut through and rock to be blasted; and after all that expense and trouble it was found impossible to lay the conduit straight, so in that trench they laid 12 cement lined pipes on a curve that was 6½ feet off the centre in 136 feet. Cables have been successfully drawn through these pipe and are in perfect working order to-day.

There has been no telephone subway construction done that it was possible to draw plans of before doing the work and live up to them. To illustrate this, in New York City the subway company adopted a plan for a manhole to be used throughout the city, to be the standard manhole. There are built in New York City nearly 3,000 manholes; of this number one manhole was built that was very near the plan adopted; none of the rest was anything like it. On South 5th avenue, 24 cement-lined pipe were laid in the following manner: At the manhole at Broome street they were able to get plenty of width to the trench but no depth to speak of. As the next manhole was approached the trench became narrower but deeper, until, when the manhole was reached there was a trench 18 inches wide and 6 feet deep. They started laying the pipe 12 wide and two rows deep, gradually narrowed them, and dropped them down until they came out at the next manhole 2 wide and 12 rows deep. These ducts are all filled with cables that are working perfectly.

It was expected in the Albany work, it being a small city, that not many obstructions would be met. But we found that the Albany folks of 100 years ago had wooden water pipe and wooden sewers.

The New England Telephone Company was the pioneer in the subway business and the good example set by it is being followed by the companies in cities of the first and second class with the exception of a few where the municipal authorities refuse to grant them the privilege to bury their wires at their own expense. Why under the sun, they should refuse this privilege, I cannot imagine.

ELECTRIC RAILWAY EARNINGS.

We have received the following business statements of three electric railways:

BINGHAMPTON (N. Y.) STREET RAILROAD COMPANY.

Thirteen miles of track, of which ten miles is the trolley system.

Statement for Quarter ending September 30, 1891.

Gross earnings		$17,670.29
Operating expenses (excluding taxes)		8,568.64
Net earnings		$9,101.65
Interest on funded debt	$2,730.00	
Taxes	1,004.93	
		3,734.93
Net income for three months		$5,366.72

WATERTOWN (N. Y.) STREET RAILROAD COMPANY.

Statement.

Gross earnings, May 20 to November 20, 1891	$12,365.06
Expenses, including interest	4,614.22
Net income for six months	$7,750.84

BUFFALO RAILWAY COMPANY.

Statement for Six Months, July 1*st*, 1891, *to January* 1*st*, 1892.

Gross earnings	$519,273.64
Operating expenses, including taxes	343,310.49
Net earnings	$175,963.15
Interest on funded debt	117,545.83
Net income for six months	$58,417.32

Operating cost, including taxes, $66\frac{11}{100}$ per cent. of earnings.

The gain in net earnings on the same period of last year was $30,415.38, equivalent to $20\frac{89}{100}$ per cent.

THE TROLLEY SYSTEM IN BOSTON.

An effort is being made to introduce the trolley system in place of horses on the street car lines of Philadelphia. There is a powerful protest against the change, however; and the remonstrants allege that wherever the trolley system has been introduced in a large city, it has so fully demonstrated its objectionable qualities that it has excited general discontent and a desire to get rid of it at any cost. Boston is one of the large cities where the trolley has been introduced, and it is proper to say that the allegation of the Philadelphia citizens is not true. On the contrary, the system is giving satisfaction, and it is rapidly being extended here.—*Boston Herald.*

TELEPHONIC EPISODES IN EUROPE.

Employees of the telephone company at Vienna have informed the Minister of Commerce that the Director of Telephones has been in the habit of instructing subordinates to call him to enable him to listen whatever the Emperor of Austria is talking with ministers or councillors or any prominent financiers.

Merchants using the telephone accuse the same Director of having immoral relations with female employees. Pending an inquiry, a Government official takes the place of the Director.

In the British House of Commons on March 22, the Right Hon. Sir James Fergusson, Postmaster General, in opposing a private bill for the establishing of a new telephone company, announced that the Government would promote a measure placing the telephone trunk lines in the hands of the post office department, which would use the present telephone systems in alliance with the trunk.

Legal Notes.

THE WESTERN UNION AND UNION PACIFIC CONTRACT ANNULLED.

The contract of 1881 between the Union Pacific Railroad Company and the Western Union Telegraph Company, by which the latter conducts the commercial telegraph business on the former's lines, must be set aside, according to a decision rendered by Justice Brewer of the Supreme Court. The case was begun in the Circuit Court for Nebraska, by the title of the United States vs. the Western Union and Union Pacific Companies, under the provisions of the act of the Fiftieth Congress known as the "Anderson law." By that law, railroad and telegraph companies which had been assisted in any way by the United States in the construction of railroad or telegraph lines were required to operate, by their own officers and employees, telegraph lines for all purposes, and exercise by themselves alone all telegraph franchises conferred on them, and the officers of the Government were directed to bring suit to annul any contract entered into in violation of the rights conferred upon the companies by the government in the franchises or grants referred to. A decree is to be entered in favor of the complainant, setting aside the contract of 1881.

Society and Club Notes.

THE ST. LOUIS ELECTRIC LIGHT CONVENTION.

President James I. Ayer, of the National Electric Light Association, has already begun to make extensive preparations to entertain the delegates to the National Convention of the Association, which meets in St. Louis next February. Isaac Taylor, the architect who has charge of the building of the new Mercantile club house at Sixth and Locust streets, has promised to complete the building by February in order that the Convention can meet there. The faculty of Washington University, the Mercantile Club, St. Louis Engineers' Club and the Merchants' Exchange will heartily co-operate in entertaining the delegates, among whom are many of the brainiest men in the country, and men pre-eminent in the science of electricity. President Ayer has received a letter from Mr. E. R. Weeks, general manager of the Kansas City Electric Light Company, instructing Mr. Ayer to call upon him for any assistance he may be able to render in making the Convention a success.

Lectures on Physics.—A course of six descriptive lectures will be given at 335 South Halsted street, Chicago, in the lecture-room over the public reading-room under the auspices of the Hull House. They will treat of the subject in an elementary manner, having in view a more comprehensive course in the fall. The importance of physics to those engaged in electrical work is acknowledged; it is an interesting study and of great practical value. The electrical mechanic and those interested in electrical work should not miss this opportunity. The lectures will be given every Wednesday evening at 8 p. m., beginning April 6.

Literature.

Heroes of the Telegraph. By J. Munro. The Religious Tract Society, London; *Fleming H. Revell Company*, New York and Chicago. 288 pp. Illus. Cloth. Price, $1.40.

THIS is a very interesting collection of biographical sketches of such men as Wheatstone, Morse, Edison, Bell, Hughes, Siemens, Lord Kelvin, Sir W. Siemens; with briefer notes on Gauss and Weber, Bain, du Moncel, Elisha Gray, Werner Siemens, etc. These careers embrace the leading events in telegraphic and telephonic development, and Mr. Munro has presented them in an attractive manner, so that while the story pleases, not a little, information is derived as to electrical principles and apparatus. It is a pity some of the biographies were not brought down to a later date, and that better portraits were not given.

Secondary Batteries. By J. T. Niblett. London, *Biggs & Co.* 267 pages; 5 by 7 inches. Price, $1.40.

THE progress which has been made, or rather the working improvements effected, in storage batteries in the last few years have been such as to render their enumeration in book form a timely undertaking, and the volume before us is well calculated to bring the reader well abreast with this progress. The author has wisely touched but briefly on the types of storage cells prominent a few years ago and brings them forward merely to present a continuous narrative. Their description serves a useful purpose, however, in showing in what direction improvements have been made. Following this the author takes up the cells of the Planté type, and describes the principal batteries under this head. This is naturally followed by a description of pasted or Faure storage cells, or if we are to follow the decision of the courts of this country, Brush cells. The various methods described in the construction of these cells will give the reader an excellent opportunity for comparison between the different types. The author next takes up the lead, zinc, copper, alkaline and other batteries, including the Reynier, Waddell-Entz, Jablochkoff anti-accumulator and others. The final chapter is devoted to the description of what the author calls solid storage cells, in which a solid electrolyte is used such as we find in the Schoop battery and in the Barber-Starkey cell. To this is added an appendix giving the various lead salts employed in the manufacture of storage batteries and the manner of their preparation, and also the various characteristics of the sulphuric acid employed in storage battery work, together with other useful information.

Taken as a whole the book is an excellent record of the present state of storage battery work, and must be commended for the general excellence of its engravings.

Die Versorgung von Städten mit Elektrischem Strom. (*The Supplying of Cities with Electric Current.*) Edited by F. Uppenborn, engineer. Berlin, *J. Springer*, 1891. Size, 7½ by 10½ inches. Price, $6.40.

IF the late Frankfort Electrical Exposition, which was so eminently successful in other ways, has been instrumental in furthering the interest of the German public in electrical matters it has certainly fulfilled its mission, but in addition to that primary object, it has served to place before electrical engineers, in concrete form, what may be considered the latest electrical advances in Germany. This standard practice may be said to have been shown, not only in the exhibits, but in what is termed the "Jubilee Book," issued to commemorate the meeting of German Municipal Governments, held in connection with the Electrical Exhibition.

This work consists of the description of the principal electric light stations installed by the most prominent manufacturers in Germany, including Siemens & Halske, Schuckert & Co., Ganz & Co., Thomson-Houston International Electric Co., C. E. Fein, and a score of others.

The descriptions are not merely perfunctory tabulations of figures and apparatus employed, but take into consideration thoroughly the problem to be solved in each case and the methods employed. The illustrations, which are of a high order of excellence, serve to make these descriptions intelligent so that even the English reader will be benefited largely by an inspection of the diagrams alone.

While it will be conceded that the art of electric lighting was created in America, a glance at this work must convince the reader of the fact that although somewhat slow in getting to work, the Germans have built all the more solidly for it, and almost without exception the stations and apparatus described show great care in design and solidity of execution. It would take us too far to enter into a discussion of the various ways in which German practice differs from ours, but we would draw special attention to the comparatively large number of instances in which storage batteries are used for central station work, and evidently to good advantage. This is a practice which, it is safe to say, could be profitably followed in this country, and it has always seemed to us a matter of regret that no real attempt has been made in this direction. We are aware that one or two small storage battery installations for central station work have been attempted, but on such a small scale that the results were not, and could not be, satisfactory. Taken in connection with central station work, we think the results of German and English practice warrant the assertion that storage batteries can be profitably employed in this field. In conclusion we might say that every central station manager can derive profitable ideas from this work, which, under the able editorship of Mr. Uppenborn, has been executed in a manner best suited to bring out the salient features of central station work.

Twenty-Third Annual Report of the Board of Railroad Commissioners (of Massachusetts). Boston, 1892.

The report of the Massachusetts Railroad Commissioners is interesting to the electrical profession principally on account of its information respecting the progress and results of the operation of electric railways in that state, not easily obtainable elsewhere.

The Commissioners again call attention to the necessity of more stringent legislative limitation of the speed of electric cars in the streets, in the absence of some efficient form of fender to serve as a protection for foot-passengers. They say and doubtless with truth, that no fender has been yet put into use which is efficient for the saving of life under the varying conditions presented by the streets and roads now occupied by electric railways. Some of the difficulties of the problem however have been removed by the use of the long and high double-truck cars which are being introduced as rapidly as possible by the West End Company of Boston. The statistics of accidents on the West End system for the year ending September 30, 1891, show a record of accidents by horse cars, 122, or 1 to 105,528 miles run, and by electric cars, 82, or 1 to 55,953 miles run. From which it appears that there are nearly twice as many accidents by electric as by horse cars, although the exhibit of the former still remains more favorable than that of the steam railroads. It is of course mainly a question of speed, and not of the particular motor used. The commissioners say: "Although motormen too frequently go at forbidden rates of speed, it speaks well for their general faithfulness, skill and alertness that so few accidents have occured;" a tribute of which the motormen are certainly not undeserving.

The Commissioners devote considerable attention—but certainly no more than the gravity of the situation calls for—to the question of the crossing at grade of steam railways by electric street lines. While no serious accident of this nature has as yet happened in the state, the commissioners very justly observe that the indications are that such accidents will happen. In reference to this matter they say:

"The rapidity with which electricity is supplanting horses as the motive power for street railways demands attention, in consequence of the fact that there is much greater danger in the passage of an electric car across steam railroad tracks than there is in the passage of a horse car across such tracks."

"Electricity is a more uncertain motive power than horses. Further than this, a car propelled by electricity is more likely to come to a standstill on a crossing than anywhere else on its route. This is owing to the difficulties of making proper connections at railroad crossings, to the increased power required to propel the cars across the steam railroad tracks, and to the chance that the jolting of the car will throw the trolley-arm off from the wire."

"Of all the dangers at grade crossings, there are none which compare in magnitude with those growing out of the electric car service. A permit should not be granted to a street railway to run electric cars across steam railroad tracks unless it is practically a matter of necessity. Where such a permit is granted, the law should require suitable crossing frogs to be laid, and signals interlocking with the gates to be provided."

There were on September 30, 1891, 28 street railway companies in the state using electricity as a motive power, all overhead or trolley systems, excepting two of minor importance on which storage batteries have been introduced. The aggregate mileage of electric railway has more than doubled during the year covered by the report, being 279.44 miles in 1891, an increase of 128.17 over the figures of 1890. The West End Company reports 81.23 miles, an increase over the preceding year of 15.77 miles.

As nearly all the principal street railways in the State are still operated with a mixed system of horse and electric cars, it is impossible to extract from the tabulated returns of receipts and expenses of operation any results of especial interest in the way of comparative statistics. It is worthy of note, however, that the total number of passengers carried on the street railways during the year was 176,090,189, being an increase of 11,205,746 over the number carried the preceding year, and exceeding the aggregate number carried on all the steam railroads in the State by no less than 68,818,347. The whole number of horses reported was 10,640, being a falling off from last year of 601, from which it appears that the great increase in the number of passengers carried by electricity has not as yet affected, to any marked extent, the emancipation of the horse. This eminently desirable result will, however, inevitably be brought about in due time.

Since the date of the report the legislature of Massachusetts has authorized the use, by existing steam railroads, of electric power, and it is not improbable that the next report of the Commissioners may embody some interesting information on this subject.

Letters to the Editor.

WORKING EFFICIENCY OF TELEGRAPH LINES.

On page 130 of the last edition of Mr. Franklin L. Pope's work on the Electric Telegraph we find:

"When key at B is open, the entire length becomes *positive*, being wholly charged from the positive pole of battery at A (Fig. 1.)

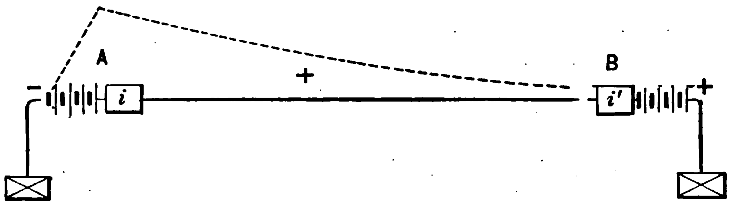


FIG. 1.

"With both keys closed, if a galvanoscope were to be connected between the point *o* and the earth (Fig. 2), it would indicate no current, because the potential *o* is at zero. Hence the quantity of current going to line from battery at A will be *the same as if the line were connected to the ground in the middle*—that is, at a point 100 miles from A."

As the foregoing statement has been emphasized by italics in the original, and several inquiries having been made privately to ascertain the true meaning involved, you will confer a favor by explaining how it is that the battery of 100 cells at A is furnishing just as much current to line through a resistance of 2,000 ohms as it does when a ground is attached to the middle of the line, reducing the resistance of the circuit of battery A to 1,000 ohms. Is it true that there is just the same consumption of zinc in one case as in the other, and are the formulas on pages 130 and 131 reliable guides?

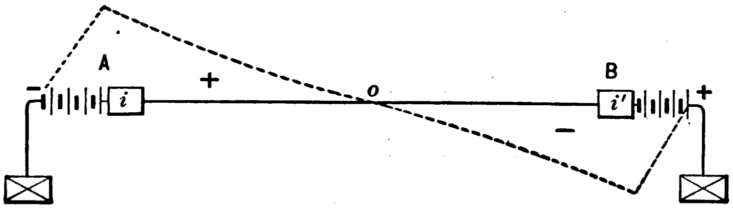

FIG. 2.

F. W. JONES.

NEW YORK.

That the battery of 100 cells in the case cited furnishes the same amount of current to the line, and that the consumption of zinc is also the same, whether the line of 1,000 ohms be connected to earth at its extremity or whether it be joined to another line of 1,000 ohms, having at its remote end another battery of 100 cells with agreeing poles, will, I think, appear from the following considerations:

In the first case we may assume—

E. M. F. of battery at A	100 volts.
Resistance of line, 1000 + instrument, 100; total	1,100 ohms.
Current (by Ohm's law) $\frac{100}{1100}$=	.099 ampere.

In the second case we have therefore—

E. M. F. of battery at A + battery at B	200 volts.
Resistance of line, 2,000 + instruments, 200; total	2,200 ohms.
Current (by Ohm's law) $\frac{200}{2200}$=	.099 ampere.

It appears, therefore, that the strength of current on the line remains unchanged, being .099 ampere in each case, and it necessarily follows that the consumption of zinc *per cell* must remain the same. And inasmuch as the quantity of zinc consumed, not counting local action, is a measure of the quantity of current generated, it seems clear that the battery at A must furnish in each case the same quantity of current to the line.

FRANKLIN L. POPE.

THE DORMAN TRANSMISSION PLAN.

In your issue of March 23, Mr. Peake criticises Mr. Dorman's high pressure transmission proposition, and points out the difficulty of insulating the machines. He evidently loses sight of the fact that where dynamos or motors are run in series their insulation resistance need be up to their individual output only. If Mr. Peake should put 260 of his four-thousand-volt constant current machines that were safe for that pressure in series, they should generate one million volts without additional insulation strain, if a corresponding number of motors of the same capacity and insulation were placed in the circuit they would stand the strain; I have seen several hundred motors working in series for months, without trouble, on a 5,000-volt circuit. They were very crude machines; not one of them would have been safe with 300 volts across their terminals, yet those same machines were used for years with apparent impunity in all sorts of industries scattered from basement to attic over a large city. If the circuit was maintained unbroken and kept clear of grounds, we considered it harmless. While for long distance transmission of power, the alternate current may become popular, it is certain the maximum capacity of the series direct current arrangement has scarcely yet been approached.

J. C. HENRY.

NEW YORK CITY, March 23, 1892.

Personal.

MR. J. STANFORD BROWN has resigned the position recently accepted by him as general manager of the *Electrical World*, etc., and will hereafter have no connection with that concern. He has resumed his practice as an electrical engineer and expert, at his old offices, 611 and 612 Electrical Exchange Building, Liberty street, and has taken up several contracts that were awaiting attention. A great many friends who appreciate Mr. Brown's good qualities welcome him back cordially to his wonted work.

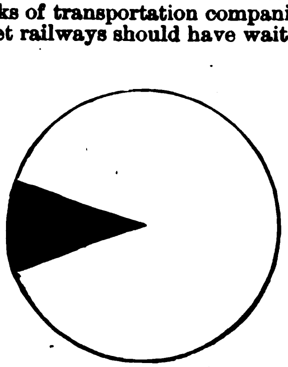
PROF. GEO. FORBES, F. R. S., of England, is shortly expected in this country on a visit combining business and pleasure; and his agent in New York makes a brief announcement on this subject in our columns this week. He is to arrive about April 9, and, as usual, will find his time fully occupied with social and professional engagements.

MR. LUCIUS T. GIBBS has recently been appointed electrical superintendent of the Milwaukee Street Railway. When the road is fully completed it will be one of the largest and best equipped in the country.

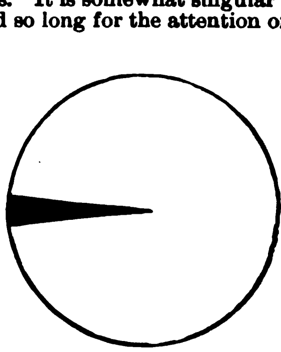
ELECTRIC AND STEAM RAILWAY NET EARNINGS.

THE Philadelphia *Stockholder* recently printed a diagram, which is here reproduced, representing the relative earnings of steam and street railways.

The entire circle, in each case, represents the capital invested. The shaded segments show the respective percentages of dividends on capital returned annually to the shareholders. An examination of the diagrams shows that the dividend segment of street railways is exactly three times as great as that of steam railways. This fact should interest those whose capital is invested in the stocks of transportation companies. It is somewhat singular that street railways should have waited so long for the attention of investors. As a general thing, hitherto, street railways have been owned by local capital, but now, with the coming of electrical operation and its high rate of net income, there seems every reason to believe that local capital everywhere will have to compete with much that has hitherto found its way to Wall street, for the acquisition there of steam road stocks and bonds.



STREET CAR DIVIDENDS.



STEAM ROAD DIVIDENDS.

Reports of Companies.

ANNUAL MEETING OF THE AMERICAN BELL TELEPHONE COMPANY.

THE annual meeting of the American Bell Telephone Company was held on March 29, in Boston.

The figures as to the number of instruments in service on Dec. 20, 1891—the close of the company's fiscal year—in comparison with the previous year, are:

INSTRUMENTS.	Dec. 20, 1891.	Dec. 20, 1890.
In the hands of licensees under rental	512,407	483,790
Increase over previous year	28,617	38,929

The report as to exchanges shows:

	1892.	1891.	Increase.
Exchanges	788	774	14
Branch offices	509	467	42
Miles of wire on poles	180,139	171,498	8,641
Miles of wire underground	70,334	54,690	15,644
Miles of wire on buildings	14,934	13,445	1,509
Miles of wire submarine	1,029	779	250
Total miles of wire	266,456	240,412	26,044
Total circuit	186,462	173,665	12,597
Total employees	8,376	7,845	531
Total stations	216,017	202,931	13,086
The estimated number of exchange connections daily in the United States, made up from actual count in most of the exchanges, is			1,584,712
Or a total per year exceeding			500,000,000

The number of daily calls per station varies in different exchanges from 2 to 16, the average throughout the United States being 7⅓, which shows an increase from last year in the average use made of the telephone by each subscriber of about 3½ per cent.

The average cost to the subscriber varies, according to the size of the exchange and character of the service, from less than 2 to 18 cents per connection.

The extra territorial lines at the present time, as compared with a year ago, show:

	Jan. 1, 1892.	Jan. 1, 1891.	Increase.
Miles of pole lines	41,298	35,541	5,757
Miles of wire	114,268	91,210	23,058

The extra-territorial connections during the year were:

Average number of connections	33,776
Or a yearly total of about	11,000,000

Reports received from the various companies operating exchanges and lines throughout the United States show a satisfactory growth of the business, and an activity, which was never more marked than at present, in making extensions and improvements of plant of such character as to ensure the best results in the way of effective and uninterrupted service.

A steady increase is recorded year by year in the number of connections required daily, by each subscriber, with other stations of his exchange, taking for comparison the successive averages of such calls throughout the country. The fact that this average of use has increased 35 per cent. within the last six years is an indication of the constantly growing value which the subscriber finds in the service of the telephone system.

While the net gain of 13,086 subscribers during 1891 is somewhat less than that of the preceding year, which is due in some measure to the severe and destructive sleet storms which visited several States in the early months of the year, it is still well above the average of the past seven years, and a large part of the increase represents subscribers for metallic circuit stations. With the advantages which this class of service affords, especially in places where trouble is experienced from the interference of strong electric currents, a largely extended use of this system is to be looked for in the near future.

As is shown in the usual table of exchange statistics, more than half of the increased mileage of exchange wire is in the form of underground conductors. There are now in operation 70,000 miles of underground wire, which is more than one-fourth of the entire exchange mileage in the country. While the use of this class of construction will, of necessity, be restricted, in the main, to the closely built sections of the larger cities, considerable extensions of the system are in progress, and the work of laying conduits and underground cable will this year be undertaken in several additional exchanges.

The entire expenditure during 1891, reported by licensees, for new lines and equipment was	$4,347,317 35
And for cost of land and buildings	800,793 93

The construction work of the American Telephone and Telegraph Company, in the completion and extension of its system, has included the building of a pole line from Pittsburgh to Harrisburg, and of a pole line from Altoona to Hazleton, and also a line westward from Pittsburgh to Cleveland by the way of New Castle. There have also been strung 10 additional wires on the lines between New York and Philadelphia and at various points minor additions of wire have been made to meet the growing demands of the business.

The total construction amounted to 463 miles of pole line; 4,942 miles of wire.

It is the intention, during the course of the current year, to fill the gap between Cleveland, Ohio, and Hammond, Ill., which last-named place is already connected by the long-distance lines with Chicago; thus giving through service between Boston, New York and Chicago. The report gives a brief summary of the litigation over the Berliner transmitter, and notes the decision given in favor of the Bell Company, last October. The present status of the cases of the Government and Western Union people against the company is detailed, and the report concludes with a statement as to the growth of and the valuable additions to the electrical department during the year.

Treasurer W. R. Driver in his report gives the ledger balances of the company as of December 31, 1891, in comparison with the previous year as below:

ASSETS.

	1891.	1890.	Inc.
Telephones	$979,117	$919,275	$59,842
Real estate	933,131	744,333	188,798
Stocks	33,180,409	32,740,580	439,829
Merchandise and machinery	8,885	8,933	*1,048
Bills and accounts receivable	3,192,918	2,034,280	1,158,638
Cash and deposits	655,823	187,935	467,888
Total	$38,950,278	$36,636,336	$2,313,942

LIABILITIES.

	1891.	1890.	Inc.
Capital stock	$15,000,000	$12,500,000	$2,500,000
Debenture bonds, 1888	2,000,000	2,000,000	....
Bills and accounts payable†	*843,909	1,334,636	*485,727
Patent account, profit and loss	10,274,913	10,516,545	*241,632
Profit and loss	5,688,567	5,645,131	43,436
Reserve	2,986,877	2,489,012	497,865
Surplus	2,151,012	2,151,012	... ...
Total	$38,950,278	$36,636,336	$2,313,942

The earnings and expenses have been as follows:

EARNINGS.

	1891.	1890.	Inc.
Rental of telephones	$3,127,783	$2,913,369	$214,414
Dividends	1,320,646	1,256,274	64,372
Extra territorial and branch lines commission	91,281	89,478	1,803
Telegraph commission	27,845	26,492	1,353
Interest	145,159	77,448	67,711
Miscellaneous	6,966	12,230	*5,264
Real estate	16,287	....	16,287
Total	$4,736,007	$4,375,291	$360,716

EXPENSES.

	1891.	1890.	Inc.

Concessions	239,396	228,574	10,822
Miscellaneous	....	106	*106
Total	$1,609,187	$1,505,873	$103,314
Total earnings	4,736,007	4,375,291	360,716
Total expenses	1,609,187	1,505,873	103,314
Net	$3,126,820	$2,869,418	$257,402

Surplus account Dec. 31, 1890	$2,151,012	(1889)	$2,151,012
Total net earnings, 1891	$5,277,832		$5,020,430
Dividends	1,725,000		1,463,918
Extra dividend	900,000		750,000
Res. for general depreciation	400,000		600,000
Res. for depreciation of instruments	101,820		55,000
Total disbursements	$3,126,820		$2,869,418
Surplus Dec. 31, 1891	2,151,012	(1890)	2,151,012

*Decrease.

†Of this amount $450,000 represents the dividend of Jan. 15, 1892, and $375,000 that of Jan. 15, 1891.

The report was accepted and approved by the stockholders.

The old board of directors was also unanimously re-elected. Their names follow: Thomas B. Bailey, Francis Blake, Charles P. Bowditch, George L. Bradley, Alex. Cochrane, William H. Forbes, Henry S. Howe, Charles Eustis Hubbard, Gardiner G. Hubbard, John E. Hudson, Charles E. Perkins, Thomas Sanders.

Two motions were then offered with the understood recommendation of the board of directors. The first was that the capital stock should be increased from $15,000,000 to $17,500,000, and the second that the new stock should be issued in the proportion of one new share for each six of the old now held. Both motions were carried unanimously. The meeting then adjourned.

COMMERCIAL CABLE COMPANY.

THE COMMERCIAL CABLE CO. has re-elected its old directors, J. G. Bennett, A. B. Chandler, George S. Coe, C. R. Hosmer, G. G. Howland, R. Irvin, Jr., J. W. Mackay, J. W. Mackay, Jr., E. C. Platt, T. Skinner, Sir D. A. Smith, W. C. Van Horne and G. G. Ward.

The year's earnings were $1,904,717.01, and expenses $819,-

392.43, leaving $1,085.324.58 profit. Dividends of 7 per cent. have been declared on $7,716,000 capital. The balance of the year's profits has been transferred to the reserve fund.

WESTERN UNION QUARTERLY REPORT.

The Western Union Telegraph Co. has declared a quarterly dividend of 1¼ per cent: for the April quarter.

The following statement exhibits the condition of the company at the close of the quarter ended December 31, 1891:

Surplus October 1, 1891, as per last Quarterly Report		$12,269,190 81
Net revenues, quarter ended December 31, 1891		1,907,166 66
		$14,176,356 97
From which deducting for—		
Dividend of 1¼ per cent. paid January 15	$1,077,408 81	
Interest on bonded debt	222,331 05	
Sinking funds	20,000 00	
		1,319,739 86
Left a surplus January 1, 1892, of		$12,856,617 11
The net revenues of the quarter ending March 31st, based upon nearly completed returns for January, partial returns for February, and estimating the business for March, will be about		$1,550,000 00
Add surplus January 1, as above		12,856,617 11
		$14,406,617 11
From which appropriating for—		
Interest on bonds	$222,330 00	
Sinking funds	20,000 00	
		242,330 00
Leaves a balance of		$14,164,287 11
It requires for a dividend of 1¼ per cent. on the capital stock		1,077,408 11
Deducting which, leaves a surplus, after paying dividend, of		$13,086,879 00

THE SHORT ELECTRIC RAILWAY COMPANY.

The annual meeting of the stockholders of the Short Electric Railway Company and the usual directors' meeting following were held at the office of the company on March 16. The following directors were elected: Sidney H. Short, Myron T. Herrick, J. Potter, John S. Bartlett, James Parmelee, Eugene Griffin and William B. Bolton. The directors met and elected the following officers for the ensuing year: J. Potter, president; S. H. Short, vice-president and chief electrician; Charles B. Lothrop, secretary and treasurer; E E. Higgins, general manager; William B. Bolton, general counsel. Mr. S. H. Short, who has been from the organization of the company its president and chief electrician, was renominated for the presidency, but declined to accept the position. He stated that owing to the growth of the company its duties had now become so onerous as to seriously interfere with his technical work and inventions, to which he desired to give his undivided attention, He therefore asked relief from his general business cares.

ELECTRIC LIGHTING AND POWER AT THE WORLD'S FAIR.

The Committee on Grounds and Buildings has decided to burn fuel oil on the Exposition grounds for running the power plant, instead of coal. This oil will cost 72½ cents per barrel of forty-two gallons. It is estimated that nearly 200,000 barrels will be used.

The question of electric arc lighting in the Exposition grounds has been decided by the Committee on Grounds and Buildings, who voted that the 5,000 or 6,000 lights required shall be secured at $20 per lamp, for 18 months' use of the apparatus. The Thomson-Houston Company, which in its bid asked $38.50 per lamp, lowered its price to $20. For that consideration it was given 3,500 lights. One thousand lamps were given to the Standard Electric Company of Chicago, and the remaining lights are to be furnished by other concerns. It seems likely that the plant for electric motor service will be put in by the Eddy Electric Manufacturing Company at $2.50 per horse power for 1,000 or 1,500 h. p. Possibly the Mather Company may do part.

Mr. A. C. F. Webb, of Sydney, New South Wales, has been appointed instructor in electrical engineering for the evening classes at the Sydney Technical College, and has begun his work. Mr. Webb has contributed to The Electrical Engineer, and is connected with the Postal Telegraphs. He is the son of Mr. H. H. Webb, secretary of the English Institution of Electrical Engineers.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 22, 1892.

Alarms and Signals:—

Electric Railway Signal, E. C. Wiley, 471,230. Filed June 18, 1891.

Consists of a base plate, two leaf springs secured thereto at their inner ends, and a double inclined depressible bar supported at its outer end upon the ends of the leaf spring.

Electric Signal for Railways, E. T. Turney, 471,296. Filed Nov. 10, 1890.

Provides means for signaling from one train to another in the front or rear and on the same track for the purpose of preventing collisions.

Boiler Feed Alarm, P. Kerekes, 471,311. Filed March 18, 1891.

Apparatus for Electric Railway Signaling, A. J. Wilson, 471,409. Filed May 23, 1891.

An electric block signal system for electric railways.

Electric Railway Signaling Apparatus, A. J. Wilson, 471,410. Filed June 15, 1891.

Similar in its object to No. 471,409.

Conductors, Conduits and Insulators:—

Safety Device for Electrical Conductors, J. Marx, 471,302. Filed July 6, 1891.

Claim:

The combination of a receptacle, electrical terminals included therein at a distance from each other and a compound in said receptacle of low resistance which becomes less conductive or non-conductive upon increase of temperature, and which connects said terminals.

Dynamos and Motors:—

Alternating Current Motor, E. Thomson, 471,155. Filed Aug. 17, 1891.

Claim 1 follows:

An alternating current motor comprising an armature and field coils inductively acting on said armature and connected to a single supply circuit, and a condenser shunting some of such field coils, whereby they are caused to lag behind the other coils in magnetic changes.

Lamps and Appurtenances:—

Carbon Holder for Arc Lamps, C. A. Pfluger, 471,190. Filed Oct. 17, 1890.

Employs a single carbon at one electrode and two or more distinct carbon at the other.

Electric Arc Lamp, H. Dewar, 471,234. Filed Sept. 15, 1891.

Consists in so adjusting the relations of the current passing through the lamp to the main and secondary magnet, etc., that the arc between the carbons is regulated and maintained under wide differences of amperage.

Disc Carbon for Arc Lamps, H. W. Libbey, 471,526. Filed Oct. 17, 1890.

Claim 4 follows:

A disc carbon having a groove or grooves on one or both sides whereby the amount of carbon consumed is regulated so that the carbon will burn equally all round.

Metal-Working:—

Electrically Welding Metals, A. De Meritens, 471,242. Filed Nov. 8, 1887.

Consists of applying at the points of junction of the metals to be welded an arc of sufficient power to fuse the metals to the required extent.

Miscellaneous:—

Wire Clamping Device, O. P. Briggs, 471,096. Filed Sept. 12, 1891.

Electrically Controlled Elevator, A. M. Coyle, 471,100. Filed May 28, 1891.

An arrangement for controlling the movements of an elevator from the different floors of a building.

Thermostatic Instrument, M. Martin, 471,130. Filed June 8, 1891.

Claim 4 follows:

In a thermostatic instrument, the combination with an active member consisting of a metallic ring of hollow terminal connections located on the opposite faces of said ring and bands or loops of fusible material encircling the said ring and joining the terminal connections thereto.

Electric Striking Mechanism for Clocks, S. C. Dickinson, 471,210. Filed Sept. 17, 1891.

Machine for Casting Grids for Secondary Batteries, A. F. Madden, 471,587. Filed July 24, 1890.

Claim 1 follows:

The combination, with a crucible, of the chamber communicating with the crucible, the mold at the top of the chamber and adapted to be moved across the latter, and the grate bars arranged at the upper end of the chamber and having their upper faces contiguous to the bottom face of the mold plate.

Railways and Appliances:—

Trolley-Wire Support, E. A. Sperry, 471,151. Filed July 9, 1891,

A trolley-wire support especially adapted to mining work.

Trolley-Pole Catcher, M. M. Wood, 471,206. Filed June 4, 1891.

Has for its object to provide means whereby the motion of the car may be utilized to bring down the trolley catcher.

Conduit for Electric Railways, F. O. Blackwell, 471,375. Filed Nov. 8, 1890.

Employs slot rails and transverse yokes placed at intervals overhanging at their upper ends the air space in the conduit, and having an opening in the overhanging portion for the removal of the insulators.

Charging-Table for Electric Railways, E. P. Usher, 471,447. Filed Aug. 31 1891.

Trolley-Wire Hanger, T. J. McTighe, 471,491. Filed July 11, 1891.

Comprises a metal plate adapted to be folded about the wire and having at its meeting point one or more registering tongues and slots forming a keyway.

Automatic Electric Block System, J. A. Carlton and H. L. Johnston, 471,525. Filed June 16, 1891.

Switches and Cut-Outs:—

Vibrating Electric Switch, J. S. Gibbs, 471,237. Filed July 3, 1891.

A switch in which the throw shall be great in comparison with range of movement of the device causing it.

Electric Switch, A. Metzger, 471,271. Filed June 6, 1891.

A jack-knife switch that shall be strong and simple of construction.

Telephones and Apparatus:—

Long-Distance Telephone System, E. Gwozdeff, 471,310. Filed Feb. 15, 1889.

Employs michrophones and telephones connected with the line by means of the separated condensers, and connected with a return line by means of condensers the capacity of which corresponds with the respective resistances of the two lines.

Telephone System, A. B. Ferdinand, 471,352. Filed June 29, 1891.

Provides means for preventing a subscriber from interfering with another while his telephone is in circuit.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Ads" are good guy wires for the circuits of trade.

MR. W. A. ROSENBAUM.

W. A. Rosenbaum.

THE development of the electrical patent business in New York city has been rapid of late years, and has given opportunities to young men of ability to make reputation and standing in a new field. Among those who have come to the front is Mr. W. A. Rosenbaum, who for some five years past has conducted the patent agency of the W. J. Johnston Co., Ltd., and who now is starting out for himself. The concern referred to is abandoning its agency, and Mr. Rosenbaum takes over the clients, library, etc., of that part of its business. Mr. Rosenbaum, whose portrait we give here in vignette, has long been engaged in patent soliciting, and one of his earliest pieces of work was taking out all the patents relating to the cable road on the Brooklyn Bridge. He has taken out a great many electrical patents, and is familiar with all branches of the industry, both as solicitor and as expert. He will occupy his old offices in the *Times* Building, this city, and will carry on a patent agency in all its departments. Freed from hampering influences, Mr. Rosenbaum may safely expect to enjoy a large share of patent work, especially in the branch with which he has so long been identified.

WESTINGHOUSE ROADS FOR NEW ENGLAND.

MR. R. S. BROWN, electric railway representative of the Westinghouse Co., reports to us the closing of one or two important contracts through the Boston office. The Fitchburg & Leominster Street Railway Co. has contracted for eight car equipments of the single-reduction type, each with two motors of 20 h. p., with one 100 h. p. generator and one 150. There will be 13 miles of track. The road is now operated by horses, but it is hoped to have the first part of the new system running by May 20. The generator will be run by engines of the Fitchburg Steam Engine Co.

The other recent contract is for the first gearless equipment in New England. Mr. Amos F. Gerald has ordered for the Waterville & Fairfield, Me., Street Railway Co. an outfit of six gearless motor cars, each with two motors. The current is to be supplied by 150 h. p of generators. Mr. Gerald is a well-known mechanician, and under his enthusiastic management the road is expected to be an exemplar of efficiency and success.

ELECTRICAL ACTIVITY AT DUBUQUE, IA.

THE DUBUQUE STREET RAILWAY CO., after a year's experience with storage cars, have decided to change to the overhead system. The Edison people will do all the line and station work. The Detroit Electrical Works will equip each car with one 40 h. p. double-reduction motors of the Rae type. The station being centrally located will prove a great saver of copper, and will be furnished with two No. 20 Edison dynamos, operated by a Sioux City Corliss engine, rated at 125 h. p. The car bodies now fitted for storage batteries will be used in addition to ten more from the St. Louis Car Co. Side-pole construction will be used with wooden poles on all lines but Main street, where Walworth iron is required under the franchise. The Edison Co. now have a crew of men on the ground doing good work, under the supervision of the city electrician and subject to his approval.

The United States Electric Light and Power Co. are receiving material for their line work. They have contracted to furnish "Standard 2,000 c. p. arc lights according to Philadelphia moonlight schedule, also on all dark and cloudy nights, for $64.95." The contract runs for three years, number of lights 200. Dividends at that price will neither be large nor frequently declared.

The Dubuque Electric Light and Power Co. are quietly holding their own, and appear to be doing all there is to be done along their route.

The Key City Electric Railway Co., who climb a grade varying from one to nearly nine per cent. for the greater portion of their trackage, about two miles, are now in the hands of a receiver and may be ordered sold at any time.

The Central Union Telephone Co. are about to place aerial cables over the portion of the city near their office.

THE SHAW ELECTRIC CRANE CO.

THE above company of Muskegon, Mich., has been extremely busy of late, to such an extent that an increase of facilities is becoming necessary in order to keep pace with orders. Among the contracts recently received are one each of 5, 10 and 20 ton cranes, for the Pittsburgh Iron & Steel Engineering Co., to be used in the new Carbon Iron Company's plate mill which they are building; one 80-ton double trolley and one 20-ton single trolley for the Midvale Steel Co.; one 20-ton crane for the Dry Dock Engine Works, Detroit; one 10-ton for the Taylor Iron & Steel Co., and one 15-ton electric jib crane for the Congdon Brake Shoe Co., Chicago. The works are now running night and day.

IMPROVEMENTS AT RICHMOND SPRINGS, N. Y.

THE ELECTRIC LIGHT AND POWER COMPANY contemplate remodeling their plant. More machines will be added, or else those in present use will be replaced by larger units worked from a compound condensing engine.

Mr. Allen Bloomfield is president, and Mr. James A. Stover, the manager of the company.

ST. NICHOLAS HOTEL, CINCINNATI, O.

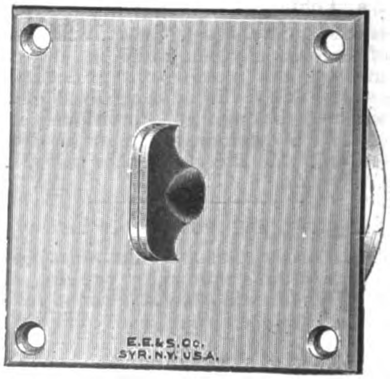
THE steam and electric lighting plant of the St. Nicholas Hotel is considered one of the best and most complete in Cincinnati. A portion of the equipment consists of a 300 h. p. battery of Root water tube boilers. The manufacturers, Messrs. Abendroth & Root Manufacturing Company, New York, report a steady demand for their specialty from the West.

UNIVERSAL RADIAL DRILL CO.

THE calendar for March, issued by the Universal Radial Drill Company, of Cincinnati, Ohio, contains a talk on suspension drills and is accompanied by an illustration showing type No. 1 of the company's manufacture.

THE FLUSH SWITCH.

THE ELECTRIC ENGINEERING AND SUPPLY CO., of Syracuse, N. Y., have recently introduced the switch shown in the accompanying illustration. This device, as its name implies, is let into the wall, its face being flush with the surface, where it attracts but little attention. The manufacturers consider this switch a step in advance of anything heretofore used for this purpose.



THE FLUSH SWITCH.

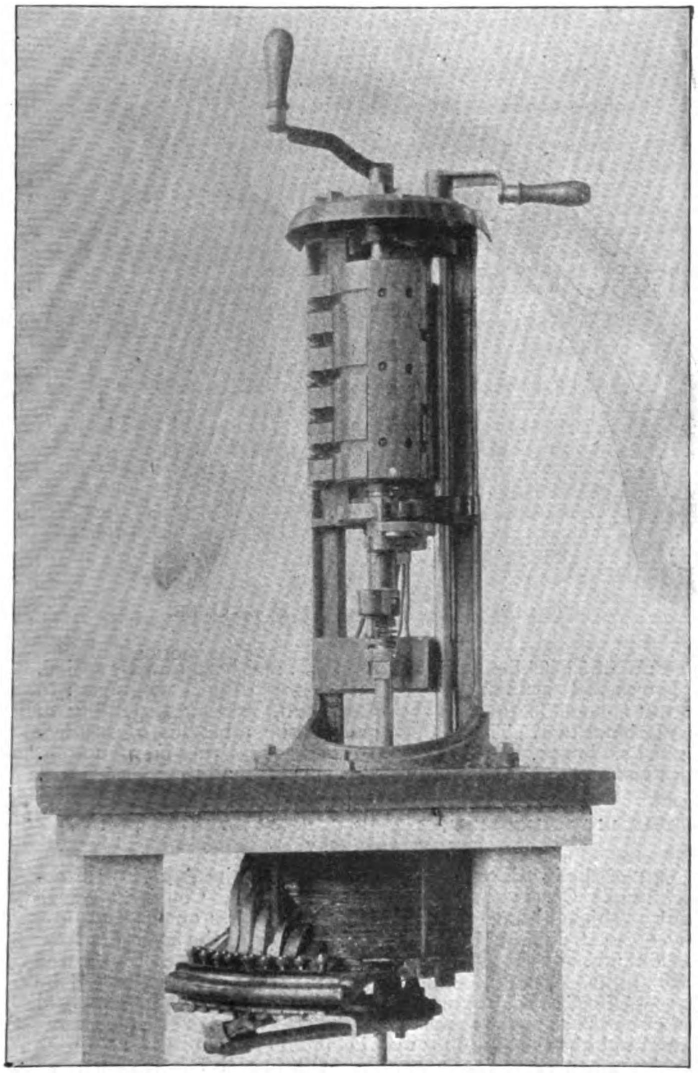
W. A. GILES, 416 Lewis Block, Pittsburgh, will handle McIntosh & Seymour, Porter and Case high-speed automatic engines, Goubert's feed-water heaters and Stratton separators, also Wing's ventilating apparatus, in this territory. Mr. Giles is favorably known as a contracting electrical and mechanical engineer.

PUNXSUTAWNEY, PA.—Some persons have just obtained a charter for an electric road in this town, with James K. North as president. The capital stock is $18,000. It is understood that no arrangements or contracts have yet been entered into by the company for the equipment of its road.

THE EDISON RAILWAY CONTROLLING SWITCH.

The Edison General Electric Company have recently devised a new type of street car controlling switch shown in the accompanying illustration, intended to take the place of the present platform switch for equipments of large motors of 25 h. p. and upwards.

In starting the car the switch-handle is turned from the position marked "off" with a "counter clockwise" movement, which has the effect of carrying the arm of the rheostat placed under the switch around on its contact segments and the resistance is gradually cut out of circuit. After this arm has been carried around and all the resistance cut out, it is released from the cylinder shaft and left locked in this position. Further movement of the handle then affects only the cylinder, and commutates the field magnet coils of the motors from series to parallel in the usual way.



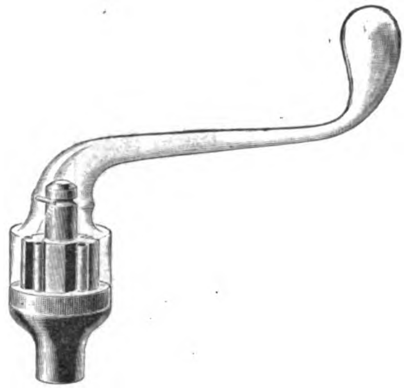
The Edison Railway Controlling Switch.

In stopping, the field coils are turned from parallel to series, the resistance coil is then again put in circuit and finally the circuit is broken by the contact lever on the last segment of the resistance coil, and not, as formerly, upon the cylinder contacts. The only caution to be observed in stopping is to see that the switch-handle is turned to the position marked "off." As the motors are reversed by means of a separate lever operating a reversing switch placed under the car, the reversing lever is connected to a shaft separated from the cylinder shaft, but interlocking with it in such a manner that it is impossible to reverse the motors until the cylinder shaft is in an "off" position. The cylinder plates and contacts are made of thick iron stampings, as experience has shown that iron is a better material to use than brass, hitherto employed. Sparking does not burn the iron as much as the brass, and greater certainty of good contact is insured. The rheostat is of the regular circular pattern resistance coil. This rheostat is protected by a galvanized iron case. The current from the trolley wire first goes through the field coils and switch cylinder for commutation, then through the armature and reversing switch, and thence through the switch contact lever and resistance coil to ground.

Only six wires are run to the platform switch; these are the field magnet wires. The three wires running to the reversing switch are of the same size as the regular armature wires, as is the wire between the metal terminal of the reversing switch and the contact lever of the rheostat. When fitting switches to cars already wired, the cables can be utilized, but the terminals of the wires left idle should be well insulated.

THE LYON BRAKE HANDLE.

We illustrate in the accompanying engraving the new Lyon brake handle which is being introduced by the Consolidated Electric Manufacturing Company, of Boston. As is well known from experience, the ordinary ratchet brake has a very short life in actual service, owing to the constant use to which it is put, wearing out the teeth and the dogs, the parts on which there is most strain. The renewal of these parts is a constant expense to the railroad company and a source of considerable revenue to the manufacturer. The Lyon brake handle is constructed in a novel manner. A series of steel rollers is placed in a V-shaped recess between the steel barrel of the handle and the head of the brake rod. It is therefore ball-bearing and noiseless in one direction, but immediately grips when the handle is pulled the other way, there being nothing stronger than a leverage of this kind. Repeated trials have been made by different roads, and the Consolidated Electric Company have received many letters and orders on account of these successful tests. They will be pleased to send samples of this brake to any road desiring to test it, and invite comparison.



The Lyon Brake Handle.

THE H. W. JOHNS MANUFACTURING COMPANY.

A very neat catalogue has been issued by the above company, of 87 Maiden Lane, this city, describing their asbestos materials for roofing and building steam pipe covering, packing, fireproof cement, etc., as well as various asbestos fabrics of their manufacture.

Vulcabeston, a compound of asbestos, india-rubber and other vulcanizable gums, manufactured by the Johns-Pratt Company of Hartford, Conn., is made up into insulating rings and washers, commutator heads, incandescent lamp bases and keys, arc lamp carbon holders and many other similar devices, and has given great satisfaction.

SIEMENS & HALSKE CO.

The above company has recently organized its American branch in Chicago with O. W. Meysenberg as president; A. W. Wright, secretary; directors, Arnold von Siemens, G. W. von Siemens, O. W. Meysenberg, A. Wright and A. von Babo. The last named has for some time past represented the Siemens & Halske interests in this country, and still carries on their office in the *Times* building in this city. We are informed on the best authority that the German house has paid in its proportion of the capital with which the new enterprise is to start.

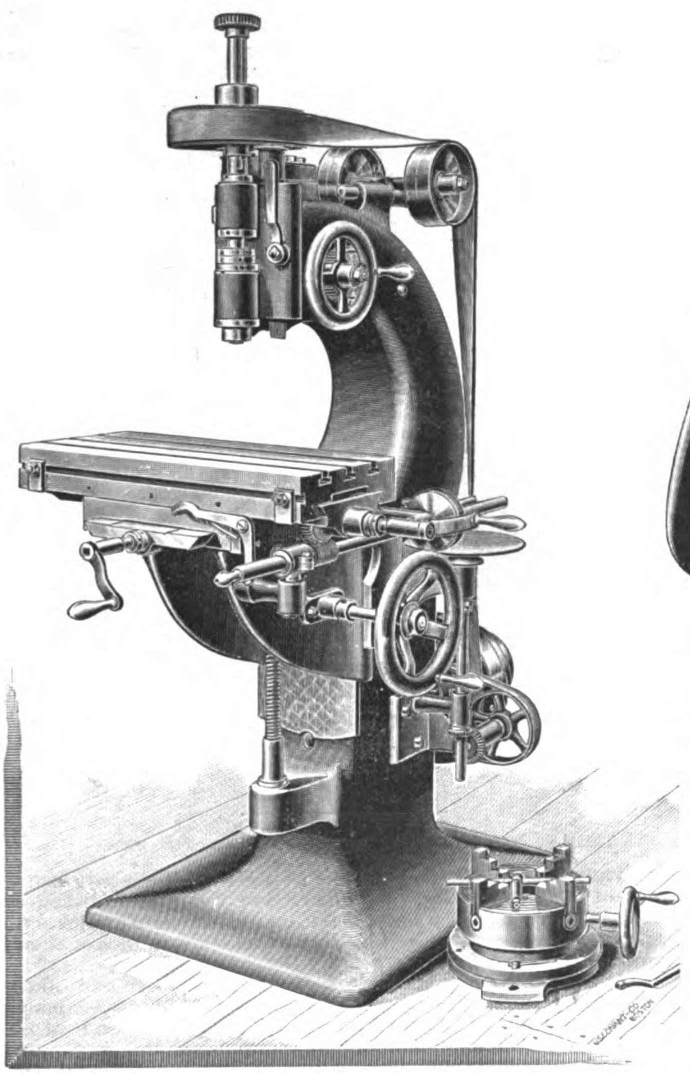
Col. G. L. Austin has merged *The Electric Railway Advertiser* in a monthly paper which he calls *Electricity and Railroading*, which will appear as a monthly devoted to the interests set forth in its title.

THE BECKER VERTICAL MILLING MACHINE.

We illustrate on this page a new vertical milling machine brought out by the John Becker Mfg. Co., of 157 Pearl street, Fitchburg, Mass., who have been making a specialty of such apparatus for electrical factories.

The belt thrust in this machine is taken upon a bearing which rests upon rollers, reducing the friction to an inconsiderable amount, while at the same time it relieves the spindle of all side pull caused by the belt. The spindle is mounted in a saddle, which is moved up or down by hand wheel shown at the right, and can be clamped by the lever seen in front. Milling tools are held in place by a threaded rod, which passes through the hollow spindle, making it easy to secure or remove them. The spindle is made of tool steel, hardened and ground to insure accuracy.

The platen has an automatic feed, which is automatically released at any desired point when moving in either direction, and the different rates of feed are obtained by means of a friction disc and roll, which latter can be placed any desired distance from the centre either side, for feeding at any desired rate in either direction. Adjustable stop gauges are provided for all movements for convenience in duplicating work. The lateral feed of table is 16 inches; cross-feed (in and out from the column) 11 inches; vertical adjustment of knee, 15¼ inches.

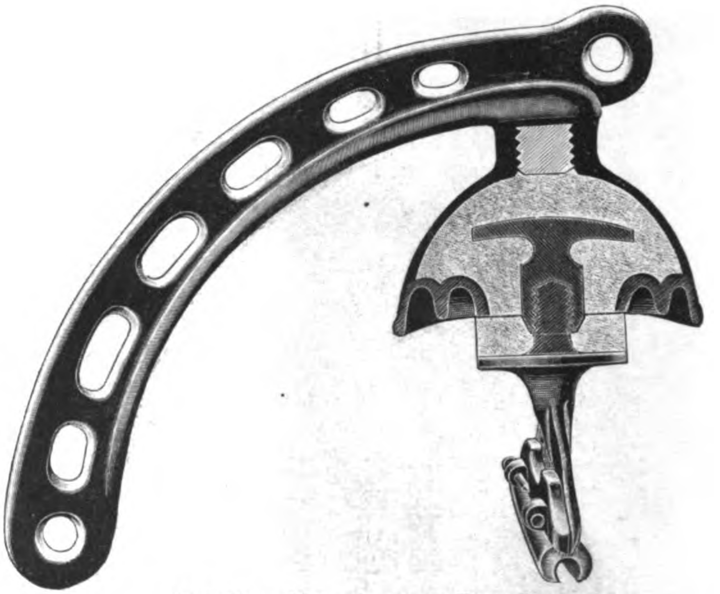


THE BECKER VERTICAL MILLING MACHINE.

There is also furnished when desired the rotary attachment shown on the floor at the side of the machine, this being provided with a 9-inch chuck, in which work may be secured and rotated by means of a worm and hand-wheel as shown. This, of course, will be found very useful for a large class of work, and any desired fixture may be fastened to the platen, T slots being provided for that purpose. Special pains have been taken to have all hand-wheels placed in the most convenient position for the operator, so that the machine may be handled with the greatest possible facility. The greatest distance from the platen to the spindle is 15¾ inches, and the machine weighs complete, ready for boxing, 1,500 pounds.

THE NEW MICA ASBETITE PULL-OVER.

OUR attention has been drawn during the past few days to the railway specialties manufactured by the Mica Asbetite Insulating Company, of 444 Pearl street, New York City. One of their specialties is an entirely new style of pull-over, of which the accompanying illustration is an excellent reproduction. As can be seen in the engraving, the device has a "bail," the upper end of which has a ⅝-inch shank which screws into the top of the bell. The bail, when desired, is made continuous, *i. e.*, to pass over to the other side, and in many cases the small hole at the upper end is convenient, when necessary to continue the span-wire. A collar on the clamp-shank when screwed up presses against the insulated disc at the bottom of the bell, making an exceedingly substantial pull-over, neat and strong and very light. The curved clamp is 3 inches long, and is curved to a radius of 26 feet. The bell used in the above pull-over is manufactured by this company and consists of a light malleable iron shell filled with their famous "Asbetite" insulating compound, forced into the shell under a pressure of 56,000 lbs. to the square inch, and hermetically sealed. This material is unaffected by any degree of heat whatever; in fact, it is possible to melt the entire shell, leaving the filling of insulation intact. The company also make all styles of insulating bells, clamps, hangers, etc., for electric railway construction. They issue a neat catalogue, which they will mail to all desiring it.



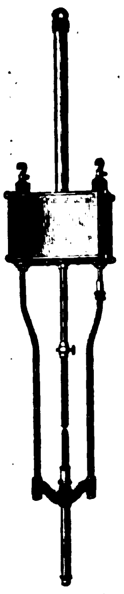
THE NEW MICA ASBETITE PULL-OVER.

THE LIGHTING OF THE ERIE COUNTY SAVINGS BANK, BUFFALO, N. Y.

ONE of the last large contracts secured by the American Electric Supply Co. is that for lighting the Erie County Savings Bank. This building when finished will possess one of the most perfect isolated plants in the country, and one of the largest in New York State, outside of New York City. The contract calls for 1,500 lights. The dynamos to generate the electricity will be three of the C. & C. Company's manufacture; two of 40,000 watts, and one of 20,000 watts capacity. A better idea of the power required to light the building may be obtained when it is said that the American Electric Supply Co. will install for this purpose three Straight Line engines, made by the Straight Line Engine Co., of Syracuse, N. Y., two to be of 60 and one of 30 h. p. The wires throughout the building will be run in conduit, manufactured by the Interior Conduit & Insulation Co. of New York City, and for which the American Electric Supply Co. are agents. Buffalonians generally will be interested in watching the progress of this work. The above work has been done under the personal supervision of the general manager, Mr. W. A. Fenn.

The American Electric Supply Co. has become well and favorably known during the single year of its incorporation. It has grown with the increased demand for electricity as a means of lighting, and for all electrical appliances of all descriptions, till to-day it stands among the leading electrical supply houses of the country. Two thousand incandescent lights are a good many, yet the company has installed that number in the Cornell University Building, including one thousand in its fine new library, and five hundred in Sage College. Regarding the Sage College plant, the New York State inspector remarked that it is the best piece of work he has ever inspected. The Law Building, in course of construction, will add 500 more to the credit of the "Supply Co."

THE HEYMANN ARC LAMP FOR INCANDESCENT CIRCUITS.



Heymann Arc Lamp.

There is at present a great demand for a good reliable arc lamp for use on incandescent circuits, and we therefore illustrate in the accompanying engraving the latest production in this line, the "Heymann" arc lamp, which is claimed to possess many new features of peculiar excellence. The Heymann lamp is purely an electric feed arc lamp, having no clockwork, gearing, racks or pinion, no solenoids nor magnetic rods, the current simply and accurately feeding the carbon downwards as it is consumed. It is a marvel of simplicity, and as there is no chance for wearing out, the parts never need renewing. The Heymann lamp requires 45 volts pressure, but will burn in series on any voltage, a suitable resistance being provided to compensate for the difference. The lamp is manufactured by the Consolidated Electric Manufacturing Company, of Boston, who will be glad to send samples to any responsible party on trial for their approbation.

TRACTION IN NEW ORLEANS.

The old franchise of the Crescent City Railroad Co., New Orleans, will be sold at auction this week, and there is a great probability of a conversion taking place from mules to electricity. It will be remembered that a long trial of storage cars was made in New Orleans, with poor results. The next time, the overhead system will be used.

A DECISION IN FAVOR OF THE STILWELL PATENT ON LIVE STEAM FEED-WATER PURIFIERS.

The U. S. Circuit Court for the Southern District of Ohio, Western Division, has just rendered a decision in favor of the Stilwell & Bierce Mf'g. Co. in a suit brought against S. N. Brown & Co. for infringement of patent No. 274,048 granted to E. R. Stilwell for feed-water heaters and purifiers. The infringing apparatus is what is known as the Hoppes purifier, made by the Hoppes Mf'g Co., of Springfield, O. The decision of Judge Sage sustains the Stilwell patent broadly.

PAINE & FRANCIS.

The news of the dissolution of this well-known old firm was first announced about a month ago, but as a matter of fact the step is only the result of what was begun in August, 1890, the firm being kept alive until this time for the purpose of complete liquidation. The firm was organized as far back as August 1885, but both members of it—Messrs Sidney B. Paine and W. H. Francis—had been active in the field several years prior to that, dating, indeed, as far back as 1881. Their active connection with Edison interests continued throughout, in various forms, and when their concern known as the New England Wiring & Construction Co. was bought out in August, 1890, by the Edison General Electric Co., they entered the employ of the latter corporation as manager and auditor, respectively, for the New England district.

QUEEN'S STANDARD PORTABLE TACHOMETERS.

Queen & Co., Philadelphia, are just placing on the market a new portable tachometer for instantly determining the speed of rotating shafts. Three spindles are geared to the rotating parts inside of the case, each one of them having a separate scale on the dial, so that the indications are direct reading throughout. A detachable point, with slightly flexible end, to fit any of the spindles, is supplied, the flexibility of which acts as a safeguard, for if made perfectly rigid there is danger of breakage when not applied exactly at right angles to the shaft.

A scale to correspond with each spindle, is graduated on the dial, and the ranges covered are: 40 to 200, 120 to 600, and 600 to 8,000, which gives a maximum capacity of 40 to 3,000 turns per minute. A conveniently shaped handle is attached to the body of the instrument so that it can easily be held in the hand.

The apparatus is well made and presents a handsome appearance, the different parts being nickel-plated.

A tachometer like this is very desirable for both expert and practical work, and those interested in the subject should write to the makers for a copy of circular No. 310.

J. H. **Siegrist, Jr.**, & Co., 313 Olive street, St. Louis, Mo., have just furnished the St. Louis and Suburban Railway Co. with one of the "Ideal" engines for their new power house.

NEW YORK NOTES.

F. P. **Little** & Co. of Buffalo, N. Y., have just closed a contract with the Connecting Terminal Railroad Co., of Buffalo, for installing a plant consisting of one 500-light Thomson-Houston dynamo, one 88 h. p. engine of the John T. Noye Manufacturing Company's make; 24 2,000 c. p. Mosher arc lamps, and 125 16 c. p. incandescent lamps, all equipped complete, ready to operate. They have also lately closed contract for wiring the Columbia Bank Building of Buffalo for incandescent lights. Business is very brisk with them at present. They are wiring the City Elevator for 300 incandescent lights and five arc lights, complete, with engine, dynamo, etc; the Bell Telephone Company's Building for 150 lights, and rewiring Weyand's Brewery for 125 lights, all of this city.

Wm. A. Mosscrop, M. E., who was formerly identified with the Edison Electric Light Co., and who for the last two years has been connected with electric railway interests, as engineer and superintendent of construction for the Woodbridge & Turner Engineering Co., has recently terminated his contract with that company and will hereafter make his headquarters with W. A. Day, M. E., 128 Oliver street, Boston. Mr. Mosscrop is to be congratulated upon entering into business relations with Mr. Day, whose agency in New England for the improved automatic engines made by the Ball & Wood Co., and whose general business in engines and boilers, and as an expert engineer has been so successful.

The Interior Conduit & Insulation Co. of 42 and 44 Broad street, New York, do not confine their operations to this country alone, as their foreign agents are placing large and satisfactory orders all the time. Mr. Everett Frazar, 124 Water street, New York, their agent for China and Japan, is shipping extensively to the above named countries. The Chinese and Japs are not behind the age, and evidently know a good thing when they see it.

The Clark Electric Co. have received a very handsome testimonial from Schwarzschild & Sulzberger, the big exporters of dressed beef, in this city, as to the efficiency of the Clark automatic safety device used on their high tension dynamo. Mr. Wm. Lewis, the chief engineer, says that he considers it a very important piece of apparatus and a valuable addition to the plant.

The Perkins Lamp.—An office has been opened at Room 114 Bennett Building, this city, by the Perkins Electric Lamp Co., for the sale of their lamps in connection with the Mather Electric Co.'s dynamos and motors.

West Troy, N. Y.—The electric light plant is to be improved and 50 new lamps are to be bought.

NEW ENGLAND NOTES.

The Beacon Vacuum Pump and Electrical Co., of Boston, are dealing in symbols—not tinkling, but striking. They are determined that electrical concerns shall use their Beacon lamp in one way or another, and so have issued a blotter in the form of an incandescent globe. It is of white material—indicative of the brilliancy of the lamp—and we are told the lasting powers of the blotter are only excelled by the long life of its prototype. No house interested in any way in electrical matters is complete without this incandescent blotter.

Albert and J. M. Anderson, of Boston, are out with a new catalogue, showing the various good points of their Ætna insulated line material for overhead railway construction. The cut on the back cover is worthy of notice, as it represents one of their insulators attached to the well-known tag of the Massachusetts Electrical Engineering Company, guaranteeing that they had tested the insulator and found an insulation of 156,000 ohms at a temperature of 70 degrees Fahr.

The Boston Electric Club will dine at Young's Hotel on Wednesday evening, April 6th, at 7.30 p. m., on which occasion Mr. William Stanley, Jr., will address the members upon "Some New Apparatus for Use with Alternate Currents." It is expected that there will be a large attendance, and Mr. Stanley's work in the development of alternate current apparatus is so well known that it goes without saying that a most profitable and interesting evening will be spent.

The Porter and Leavitt Manufacturing Company, of Providence, R. I., report that they have had remarkable success with their small motors, and are as busy as possible. They have had to increase their manufacturing facilities largely, owing to the rush of business, and have now a large and well-equipped factory. They have received many orders from foreign countries, many of them, it is gratifying to note, due to their advertisement in **The Electrical Engineer**.

The Freeman-Holland Company, of Boston, report that they have secured a contract from the Hull Electric Light and Power Company, of Hull, Mass., for two 1,500-light alternating generators, and 4,000-light capacity of transformers and lamps.

The New England Electric Club announces through its treasurer, Mr. A. O. Smith, that the directors have leased the premises of No. 14 Bosworth street, Boston, for four years, for the purposes of occupation as a club house. It is hoped that the rooms will be ready for occupation by the middle of April, and work will at once be commenced fitting up the billiard-room, parlor, reception, dining and other rooms.

Berlin Iron Bridge Co.—The new machine shop for the Henry R. Worthington Hydraulic Works at South Brooklyn, N. Y., will be built of iron by the Berlin Iron Bridge Co., of East Berlin, Conn. The building is 200 feet long by 50 feet wide with a 20-ton Sellers traveling crane. The building is made from the designs of the Berlin Company, who furnish it complete, including the foundations and the brick-work.

The Combination Car Company, of Boston, whose car was recently described in these columns, tendered a reception this week to the officials of the different street railways in the vicinity, for the purpose of introducing their combination car to notice. Many representative gentlemen were present, and a pleasant afternoon was spent, the general opinion being that the car had a great field of usefulness before it.

Mr. F. A. Magee, of 126 Pearl street, Boston, has been appointed New England agent for the Bishop Gutta-Percha Company, of New York, and will hereafter carry a large stockof the general sizes of this company's well-known high-class wire. Mr. Magee will continue to handle the Cleveland transformers, cut-outs and railway switches, as well as the Underwood belting and Dodge split pulleys

The Bridgeport Electric Light Company, of Bridgeport, Conn., are making arrangements to push the erection of their new station, and have bought a piece of ground facing the harbor 210 feet by 100 feet, where they will be able to secure plenty of water for condensing purposes.

The Union Electric Manufacturing Company, of Bridgeport, continue to flourish and are enjoying a good run on their specialties.

PHILADELPHIA NOTES.

Merchant & Co., the great metal dealers and specialists of this city, have long been noted for the clever uniquity of their advertising. It is they, for instance, who are entitled to the credit of first using Brownies in the advertising field, while many of their trade mark efforts are masterpieces. Mr. Malcomb Marvel, whoever he many be, has now written a very pithy and picturesque account of the concern entitled: "The Advertising History of a great House," and a reprint of it from *Business* is being used to good advantage.

Henry Brunt & Son, porcelain manufacturers, of East Liverpool, Ohio, have erected a large factory for the manufacture of hard porcelain for electrical purposes. They have a well equipped machine shop in connection, where dies are made for simple and intricate shapes. This plant has been established for years, and is favorably known as the Riverside Manufacturing Co. They go into this branch of their business with a determination to keep up their reputation as making first-class goods at a very reasonable figure.

Mr. T. J. Cope, 8 North 6th St., has been abundantly blessed with orders of late for the Cope "Automatic Come-Along" or "Wire-Puller," of which he is the inventor and sole manufacturer. These come-alongs possess several advantages, as is shown on another page of this paper.

Mr. T. L. Townsend, of the Partrick & Carter Co., has just returned from a very successful trip West. It was our good fortune to witness his taking several large orders in Pittsburgh and Allegheny last week, which would aggregate over $4,000.

W. C. McIntire & Co., of this city, are meeting with very gratifying results in the sales of their new "Crown" shade or reflector.

James J. Murray & Co., glass globe and shade manufacturers, report business brisk. They are at present working on orders from parties in Central and South America.

WESTERN NOTES.

The Sunbeam Incandescent Lamp Co. report that their factory is pushed with orders for Sunbeams, and they have done more business during the last month than any previous one. This speaks volumes for the favorable way in which their lamps are regarded by the public.

Mr. G. M. Angier, recently assistant manager of the Knapp Electrical Works, has resigned his position to accept a similar one with the Mather Electric Co. of Manchester, Conn. Mr. Angier will be missed by his many friends in Chicago, all of whom will wish him success in the East.

Mr. F. W. Cushing, general Western agent of Kerite insulated wire and cables, has fitted up his new suite of offices at No. 225 Dearborn street very handsomely, and has a most complete line of samples of all sorts and sizes of wire, and keeps on hand in his storeroom a large stock, enabling him to make very prompt shipments. Mr. Cushing is having framed some handsome pictures of twenty of the prominent electricians of the world, which he intends hanging on the walls of his private office, thus giving it a very unique and interesting feature. In line with the adornments for his office are Mr. Cushing's striking advertisements. in which he has shown the handsome full-page cuts of several of Chicago's large office buildings which are wired with Kerite. He is doing a large business already, and users of wire recognize the improvements which have recently been made in these wires and cables to fit them particularly for electric lighting and other work of the severest kind to which an insulated wire can be subjected.

Burton Electric Co.—The annual meeting of the Burton Electric Co. was held on March 23, at the offices of the company in Richmond, Va., and Mr. W. R. Mason, of Chicago, was re-elected to the position of president. The following resolution was unanimously adopted by the stock holders: "Resolved, That the stockholders of the Burton Electric Co. hereby tender to Mr. W. R. Mason their acknowledgments of their high appreciation of the efficient and successful manner in which he has conducted the affairs of the company during the past year and that the secretary be instructed to inform him of his unanimous re-election to the presidency for the ensuing year, with a copy of this resolution." This is a graceful tribute to Mr. Mason's well-known executive business ability, and his many friends will appreciate the compliment tendered him.

The Fort Wayne Electric Co. have fitted up their offices at 185 Dearborn street, which were entirely devastated by the recent fire, in a very handsome manner. The decorations are of the Moorish order and exceedingly striking, and the lighting, which is effected by means of bunches of incandescents in which opalescent shades are attached to the ceiling, is very beautiful. All the finishings and office furniture are of oak, and tiled flooring has been put in, and the appearance of their quarters is exceedingly attractive and business like. The lighting and decorative effects were devised by Mr. W. H. Harding, the manager of the Central Electric Light Co., who operate the Fort Wayne Electric Co.'s system in this city.

The Central Electric Company are preparing a house-goods catalogue, which they hope to have ready in April. The catalogue will be replete with cuts and descriptive matter of the latest designs in this department of their business. They are sending out a very handsome circular in reference to tested fuse wire and terminal fuses. The circular contains an article on fuse wire that was read before the Chicago Electric Club, December 7, 1891, by Mr. Elmer A. Sperry, and contains valuable information on this most important subject.

The Electrical Supply Co., Chicago, have secured the exclusive agency in the United States for the well-known and popular Boston trolley, manufactured by Albert & J. M. Anderson This trolley has met with very general adoption, and is a prime favorite. The Electrical Supply Co. feel that in this article as equipped with their Reedfeed trolley wheel hub they have a combination of many excellent features. They keep a full supply of parts on hand.

Mr. D. B. Dean, who for some time past has been connected with the Electric Mdse. Co. as selling representative, has resigned his position to take a similar one with the McGuire Mfg. Co. Mr. W. R. Mason, general manager of the Electric Mdse. Co., regrets the loss of Mr. Dean, as he has done excellent work in the past, and unites, with his many friends, in wishing him success in his new connection.

Detroit Electrical Works.—The Chicago office of the Detroit Electrical Works, which is now at 481 Rookery, will, after April 15, be in suite 917–918 Monadnock Building, corner Dearborn and Jackson streets. Mr. L. E. Myers, special agent of the company, is the manager of the Chicago office, and Mr. H. A. Kinney, well known in electrical circles, is now connected with this office.

The Electric Appliance Company report having closed arrangements with the New York and Ohio Company to handle the Packard lamp exclusively in Indiana and Lower Michigan, and have already commenced to lay plans for a large future lamp business in this territory. The Appliance Company are also pushing the sale of "Canvas Jacket" wire and of the "Flexible Conduit."

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XIII. APRIL 13, 1892. No. 206.

NOTES ON THE DETERMINATION OF WIRE FOR MULTIPLE ARC DISTRIBUTION.

BY

J. Lester Woodbridge

THE problems which the electrical engineer encounters in laying out a system of conductors for electrical distribution are among the most important, and often the most intricate, that he is called upon to solve. They are, as a rule, capable of exact mathematical solution, when the conditions are known, yet we too often see them dismissed with a more or less approximate guess at the result, or with a "rule-of-thumb" method of solution, both of which frequently hit very wide of the mark. Some of those problems have already been discussed in these columns, and have evoked a very general interest in the subjects treated. I do not propose, however, to review, in any sense, the subject of "electrical determinations," so called, but would call attention to a few points that are frequently met with.

To lead up to them, consider first an elementary arrangement shown in diagram Fig. 1. In this diagram I have represented the central station at S, and the points where the current is to be applied at A, B, C, D, etc. As the problem is usually presented, we have a given loss which must not be exceeded at any point in the system of conductors.

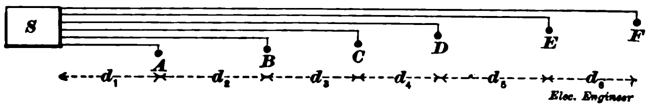


FIG. 1.

If the wiring is arranged as in Fig. 1, (which represents only one side of the system, the return wires being omitted), the calculation is very simple, each wire being determined by the well-known formula,

$$\text{cir. mils} = \frac{10.5 \times \text{amperes} \times \text{feet}}{\text{volts drop}};$$

and if V is the given maximum drops in volts; $a_1\ a_2\ a_3$, etc., the current in amperes carried by SA, SB, SC, etc., respectively; $(c.\,m.)_{A}$, $(c.\,m.)_{B}$, $(c.\,m.)_{C}$, etc., the circular millage of the respective wires; d_1, d_2, d_3, etc., the distance in feet between S and A, A and B, B and C, etc., respectively; we have,

$$(c.\,m.)_{A} = \frac{10.5\ a_1\ d_1}{V};\ (c.\,m.)_{B} = \frac{10.5\ a_2\ (d_1 + d_2)}{V}, \text{ etc.} \quad (1)$$

$$\text{and } V = \frac{10.5\ a_1\ d_1}{(c.\,m.)_{A}} = \frac{10.5\ a_1\ (d_1 + d_2)}{(c\ \ m.)_{B}} = \text{etc.} \quad (2)$$

The above is the arrangement usually adopted for the main supply feeders from a central electric light station to the various centres of distribution, for incandescent lighting, and it gives, under full load, the same drop on each feeder, and a uniform potential at the points A, B, C, etc.

But it is in many cases found advisable to unite these separate lines into a single wire of varying section, especially in railway installations, where absolute uniformity of potential is not so essential; and just here is where the mistake is so frequently made, in supposing that by substituting a single wire of a section equal, at each point, to the sum of the sections of the smaller wires at that point, the same results will follow. The fact is that, instead of getting a uniform potential at A, B, C, etc., as before, we shall evidently have a higher potential at A, and a lower potential at F, Fig. 2, and the drop at the extreme end of the circuit will be greater than the maximum allowable; it will be the sum of the several losses between S and A, A and B, B and C, etc.; or,

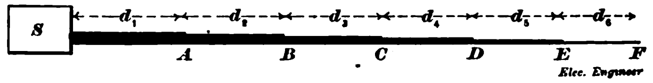

FIG. 2.

$$V_F = \frac{10.5 \times (a_1 + a_2 + \ldots a_6)\ d_1}{(c.\,m.)_{SA}}$$
$$+ \frac{10.5\ (a_2 + a_3 + \ldots + a_6)\ d_2}{(c.\,m.)_{AB}} + \ldots . + \frac{10.5\ a_6\ d_6}{(c.\ m.)_{EF}}; \quad (3)$$

where $(c.\ m.)_{SA}$, $(c.\ m.)_{AB}$ $(c.\ m.)_{BC}$, etc., represent the circular millage of the single conductor between S and A, A and B, B and C, etc., and V_F is the drop in volts between S and F.

If the wire were made of uniform circular millage, represented by $(c.\ m.)_{U}$ as in Fig. 3, the above expression becomes

$$V_F = \frac{10.5 \times (a_1 + a_2 + \ldots + a_6)\ d_1}{(c.\ m.)_{U}}$$
$$+ \frac{10.5\ (a_2 + a_3 + \ldots\ a_6)\ d_2}{(c.\ m.)_{U}} + \ldots . + \frac{10.5\ a_6\ d_6}{(c.\,m.)_{U}} \quad (4)$$

or, rearranging,

$$V_F = \frac{10\ 5 \times a_6\ (d_1 + d_2 + \ldots + d_6)}{(c.\ m.)_{U}}$$
$$+ \frac{10.5 \times a_5\ (d_1 + d_2 + \ldots + d_5)}{(c.\ m.)_{U}} + \ldots . + \frac{10.5\ a_1\ d_1}{(c.\,m.)_{U}} \quad (5)$$

Substituting equations (2) in this, it becomes,

$$V_F = \frac{V\ (c.\ m\ )_{A}}{(c.\ m.)_{U}} + \frac{V\ (c.\ m.)_{B}}{(c.\ m.)_{U}} + \ldots . + \frac{V\ (c.\ m.)_{F}}{(c.\ m.)_{U}} \quad (6)$$

In order that this expression shall be equal to V, we must have $(c.\ m)_{U} = (c.\,m.)_{A} + (c.\ m.)_{B} + \ldots . + (c.\ m.)_{F}$

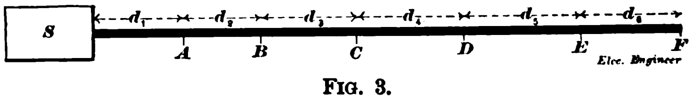

FIG. 3.

In other words, if for the wires in Fig. 1, there is substituted a single wire of uniform section, that section must be equal throughout its whole length to the aggregate circular millage of all the wires, taken at the point where that aggregate is greatest, (*i. e.*, at S), in order to obtain the same drop at the point F as before. This arrangement, therefore, requires a greater amount of copper than that shown in Fig. 1, to secure the same maximum drop; but it is to be noted that this additional copper effects a reduction in the *average* loss on the line.

The question then arises, could not an arrangement similar to that in Fig. 2 be devised, with a tapering conductor, which would require less copper than one of uniform size, for the same maximum drop at the extreme end. Thus we have the problem: To find what arrangement of tapering conductor, for a given distribution of load, will require a mimimum weight of copper for a given drop at the extreme end.

To solve this problem, assume first the simplest case, as in Fig. 4, where the conductor is tapped at two points, A and B, the current consumed at A being a_1, and at B, a_2. The volts drop at B will be

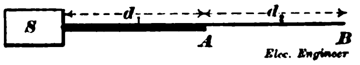

FIG. 4.

$$\frac{10.5 \times (a_1 + a_2)\, d_1}{(c.\ m.)_{SA}} + \frac{10.5\ a_2\, d_2}{(c.\ m.)_{AB}} = V_B \qquad (7)$$

The weight of copper wire per foot is $w = \frac{c.\ m.}{k}$, where $k = 330{,}400$; and we have

$$(c.\ m.)_{SA} = k\, w_{SA}; \qquad (8)$$
$$(c.\ m.)_{AB} = k\, w_{AB} \qquad (9)$$

when w_{SA} and w_{AB} are the weights per foot of wire between S and A, and A and B, respectively. Substituting these expressions in (7) we have

$$V_B = \frac{10.5 \times (a_1 + a_2)\, d_1}{k\, w_{SA}} + \frac{10.5\ a_2\, d_2}{k\, w_{AB}} \qquad (10)$$

The total weight of copper will be

$$d_1\, w_{SA} + d_2\, w_{AB} = W, \qquad (11)$$

which is to be a minimum.

Let
$$\frac{w_{SA}}{w_{AB}} = r; \qquad (12)$$

then (10) becomes

$$V_B\, k\, w_{SA} = 10.5 \times (a_1 + a_2)\, d_1 + 10.5\ a_2\, d_2\, r;$$

and (11) becomes
$$\frac{W}{w_{SA}} = \frac{d_1 r + d_2}{r} \qquad (13)$$

Multiplying;

$$V_B\, W k = 10.5 \times [\,(a_1 + a_2)\, d_1 + a_2\, d_2\, r] \times \frac{d_1\, r + d_2}{r};$$

from which
$$W = \frac{10.5}{V_B\, k} \times \left[(a_1 + a_2)\, d_1^2 + a_2\, d_2^2 + a_2\, d_1\, d_2\, r + \frac{(a_1 + a_2)\, d_1\, d_2}{r} \right],$$

which is to be solved for a minimum with respect to r.

Omitting constants we have:

$$\frac{d}{dr}\left(a_2 r + \frac{a_1 + a_2}{r}\right) = a_2 - \frac{a_1 + a_2}{r^2} = 0, \text{ and } r^2 = \frac{a_1 + a_2}{a_2},$$

from which we have,
$$\frac{w_{SA}}{w_{AB}} = \frac{\sqrt{a_1 + a_2}}{\sqrt{a_1}}.$$

That is, for this particular case the weight per foot, and therefore the circular millage at each point, should be directly proportional to the square root of the current in amperes at that point.

Now take the general case of a tapering conductor tapped at any number of points, as in Fig. 2. Suppose the law for minimum weight to be different from that just given, and suppose that the conductor be arranged in accordance with the correct law to secure the minimum weight of copper; and suppose that for any two contiguous sections, CD and DE, the circular millage be *not* proportional to the square root of the current carried. We can without changing the drop between C and E, and, therefore, without altering the maximum drop at the end of the line, make the circular millage of these two sections proportional to the square root of the currents carried. From what has just been proven, this arrangement will require less copper than before on these two sections, and therefore less in the total, since the other portions of the conductor are not changed. But this is contrary to the hypothesis assumed, viz., that we could have a correct arrangement for minimum weight, under a different law from that proven for two sections; hence that hypothesis is false, and the law is general, since it must apply to any two contiguous sections of the conductor, and therefore to all parts of the conductor; and we have the following

RULE.

To arrange a tapering conductor, tapped at several points, so as to secure the minimum weight of copper for a given drop at the extreme end (or what is the same thing, to secure a minimum drop at the extreme end with a given weight of copper), the circular millage at each point should be directly proportional to the square root of the current in amperes passing that point.

It sometimes occurs that the *total loss of energy* (in watts or horse power) on the whole line is a more important item than the drop in volts at the extreme end. Let this total loss in watts be represented by L. Again take the simplest case of a conductor tapped at two points, Fig. 4. The drop in volts between S and A will be $\frac{10.5\ (a_1 + a_2)\, d_1}{(c.\ m.)_{SA}}$ and the watts loss will be $\frac{10.5 \times (a_1 + a_2)^2 d_1}{(c.\ m.)_{SA}}$ or substituting (8), $\frac{10.5 \times (a_1 + a_2)^2 d_1}{k\, w_{SA}}$.

Similarly, the watts loss between A and B will be

$$\frac{10.5 \times a_2^2\, d_2}{k\, w_{AB}}$$

and $L = \frac{10.5 \times (a_1 + a_2)^2\, d_1}{k\, w_{SA}} + \frac{10.5 \times a_2^2\, d_2}{k\, w_{AB}}$; or substituting (12), $L = \frac{10.5}{k\, w_{SA}} [(a_1 + a_2)^2\, d_1 + a_2^2\, d_2\, r]$.

As before, (13), $\frac{W}{w_{SA}} = \frac{d_1\, r + d_2}{r}$, which gives

$$L = \frac{10.5}{W\, k}\left[(a_1 + a_2)^2 d_1^2 + a_2^2\, d_2^2 + a_2^2\, d_1\, d_2\, r + \frac{(a_1 + a_2)^2\, d_1\, d_2}{r}\right];$$

and for L a minimum, we have

$$r = \frac{a_1 + a_2}{a_2} = \frac{w_{SA}}{w_{AB}}.$$

That is, the cross section should be proportional to the current. By the same process of reasoning as before we can show that this rule will apply to a conductor tapped at any number of points, and we have the general

RULE.

To distribute a given weight of copper in a conductor tapped at several points in such a manner as to secure the least possible total loss of energy in watts or horse power, the cross-section should be proportional at every point to the current passing that point.

These two rules, while they may in many cases be incapable of exact application, owing to varying or unknown conditions, will always serve as a guide in laying out a system of conductors, and will often effect a considerable saving in investment for copper.

A NEW PRIMARY BATTERY.

MR. MOND (of the firm of Brunner, Mond) has found that by passing mixed hydrogen and carbonic oxide over nickel and cobalt he can separate them, and then, by applying the hydrogen, as in Grove's experiment, to strips of platinum, he gets a powerful battery. This battery will yield, it is stated, 50 per cent. of the total energy in the hydrogen absorbed.

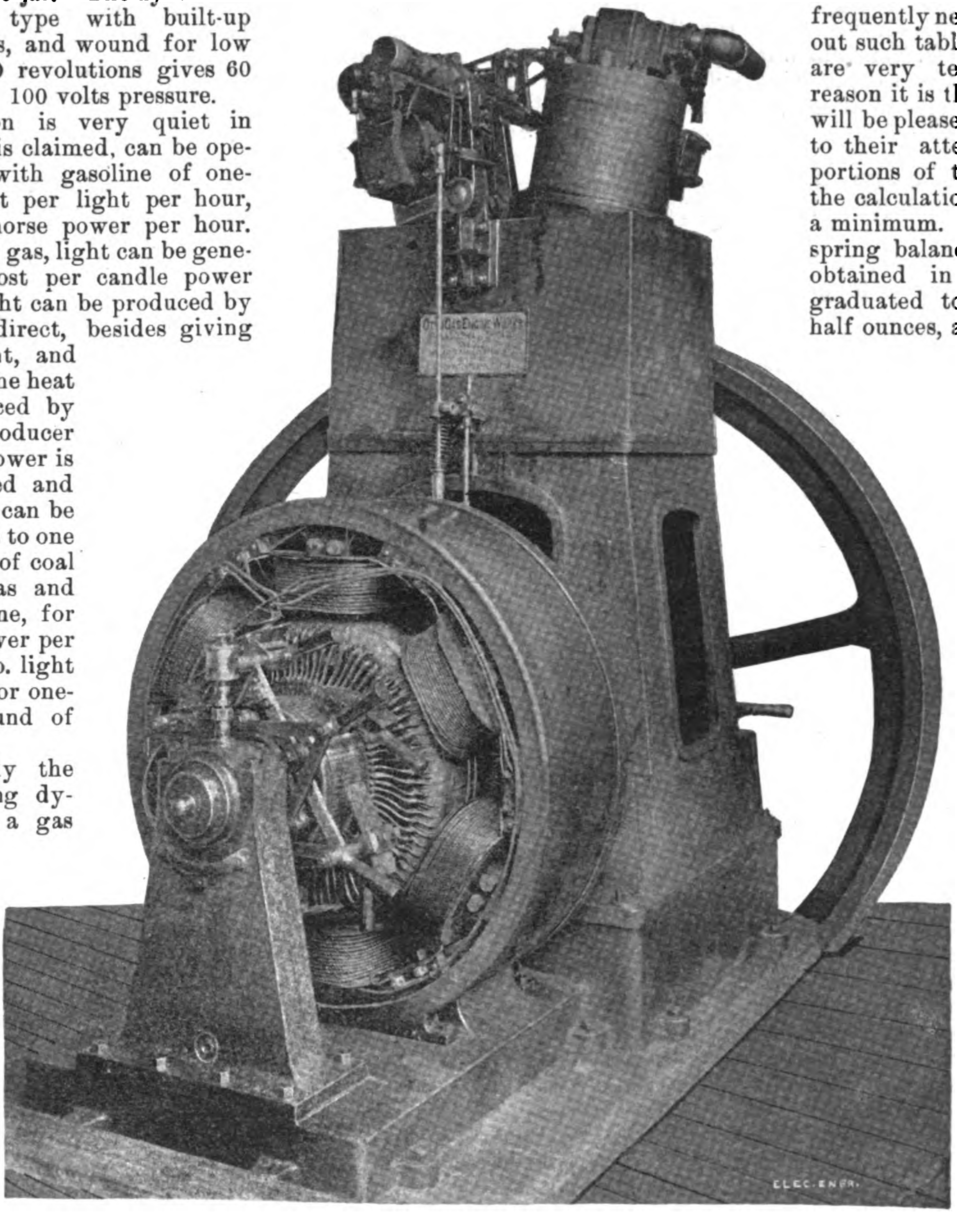
COMBINED GAS ENGINE AND DYNAMO FOR ELECTRIC LIGHTING.

THE accompanying illustration represents a 35 h. p. gas or gasoline engine, and slow speed multipolar dynamo, capable of giving 350 16 c. p. incandescent lights or 35 arc lights. The gas engine is of the well-known Otto type, designed and built by the Otto Gas Engine Works, of Philadelphia. It has the same valves as are used on the ordinary Otto engine, but has two cylinders with cranks at 180 degrees, so as to balance and to run at a high speed without perceptible jar. The dynamo is of the six-pole type with built-up wrought iron fields, and wound for low tension, and at 250 revolutions gives 60 volts, and at 300, 100 volts pressure.

The combination is very quiet in operation and, it is claimed, can be operated at a cost with gasoline of one-tenth of one cent per light per hour, or one cent per horse power per hour. With illuminating gas, light can be generated at a less cost per candle power than the same light can be produced by burning the gas direct, besides giving a much better light, and doing away with the heat of the light produced by the gas. With producer gas the cost of power is still further reduced and one horse power can be produced from one to one and a half pounds of coal converted into gas and used in the engine, for each one horse power per hour, or one 16 c. p. light can be produced for one-tenth of one pound of coal per hour.

This is probably the first direct running dynamo driven by a gas engine, and as such is a very interesting experiment, it having been assumed that a gas engine could not be made to run steadily enough to give a steady light. But with a heavy fly-wheel and the double-cylinder arrangement, it has been found practicable to bring down the variation to less than one-half volt, due to the impulse of explosion of the charge in the cylinder, which is scarcely noticeable in the lights; and, where a storage battery is used in combination, a perfect light is given at a very low cost. Where a steam plant and a skilled engineer are not desirable, this combination affords a solution of the problem. By turning the switch the storage batteries are made to start the engine, the dynamo acting as a motor until the engine is started; then, by shifting the switch, it can be made either to store the batteries again or to furnish the current to the lights direct.

This combination is due to Mr. George S. Strong, of this city and one of these engines and dynamos can be seen in operation at the works of the Otto Gas Engine Co., in Philadelphia.



OTTO GAS ENGINE WITH DIRECT COUPLED DYNAMO.

PRONY BRAKE CALCULATIONS.

BY

Chas. E. Emery

SOME experimenters are provided with tables showing by inspection the horse power due to a given number of revolutions and a given strain on the scale of a Prony brake. Even then interpolations are frequently necessary, and without such table the calculations are very tedious. For this reason it is thought that many will be pleased to have brought to their attention such proportions of the apparatus that the calculations are reduced to a minimum. For small powers spring balances can be readily obtained in stock that are graduated to ounces or even half ounces, and in any case it is as easy to reduce to ounces as to decimals of a pound. If, then, the distance from the centre of the jaws gripping the pulley to the point of suspension of the balance be made 10.084 inches, instead of one foot, as is customary, *the horse power may be found at once by simply multiplying the strain on the scale, reduced to ounces, by the number of revolutions per minute and pointing off five places of decimals.*

For if $P =$ the horse power, $R =$ the radius in feet and $R_1 =$ the radius in inches; $w =$ the weight in pounds and $z =$ the weight in ounces, and $r =$ the revolutions per minute, we have:

$$P = \frac{2\pi R w r}{33000} = \frac{R_1 z r}{1008403}.$$

If R_1 be made 10.084 inches, as proposed, evidently

$$P = \frac{z r}{100000} = \frac{z r}{10^5}.$$

A double-flanged pulley should always be used with the brake. The tendency of the wooden jaws to grip on the pulley as it becomes heated may be prevented to a considerable extent by putting a spring under the nut on one of the clamping bolts, and this arrangement is also conducive to steadiness of the balance spring.

HOW HOUSE SERVICES ARE PUT IN BY THE EDISON ELECTRIC LIGHT COMPANY, OF PHILADELPHIA.

BY

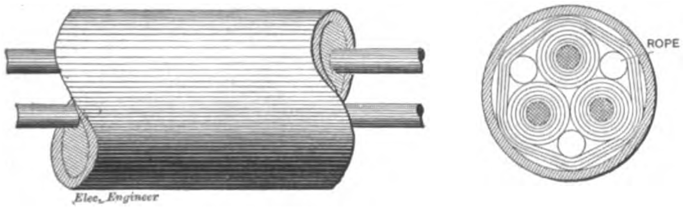
Jos. D. Israel

(Superintendent of Street Work.)

In the March 30 issue of The Electrical Engineer, there appeared an instructive article on the manner of putting in a house service from the Edison three-wire system in New York, from which it appears that the Edison companies have not as yet departed wholly from the underground tubing, and adopted the more economical and advantageous system of cable connections for service work. As we live to learn, it would not be amiss to relate briefly the positive success of cable service connections as laid and maintained by the Edison Electric Light Company, of Philadelphia.

There is a general belief in the world at large that nothing of an original or progressive nature can receive its birth or early nourishment in the "City of Brotherly Love." In spite of this prejudice the conviction is being carried to the electrical world that Philadelphia is abreast of the times in matters of moment to the electrician.

The cable services of the Philadelphia Edison Company should attract the attention of all electric companies maintaining an underground system. The Edison companies, particularly, should examine this means of reducing their expenses.



Making a House Service in Philadelphia.

The cable employed consists of the three copper conductors of the desired diameter. The Philadelphia company uses three sizes, of Nos. 41, 80 and 160, Edison Standard Gauge. They find these sizes available for all practical cases. Two services of 160 cable are used in places where an extraordinary load is to be carried.

The coppers are separated by spiral windings of hemp rope (see Fig.) the space between being filled in with resin and cotton seed oil. The rope braid is wrapped around the cable, and then it is encased in a one-eighth inch lead covering. The lead is painted with a waterproof paint. The resistance is very high, and the practical problem thus solved is simply to give the *coppers* more rope as insulation.

The advantages of using this cable in place of a rigid iron tube are readily observed by following the manner of putting in a service. For this purpose the trench is dug and the coupling box on the main is uncovered. On account of all services being made on a live line it is not good policy to compel your men to work in a tunnel. Give them as much working room as possible, and insist on the best of workmanship being executed. This will save money in the end, as there will be fewer "burn-outs" to locate.

Do not tear up the sidewalk and get the company into the bad graces of the subscriber. Locate the point of entrance into the cellar, break the wall and then bore under the sidewalk. An ordinary post-hole auger will do the work. In four years' experience it was found that the small number of places in which the auger had to be abandoned and the sidewalk torn up were overwhelmingly outnumbered by the successful use of the auger in over 95 per cent. of the undertakings.

The trench is ready, and now comes the advantage of cable over tubing. The measurement is taken, and only one piece of cable is required. What matters it if there is a gas main to go under and then a telephone conduit to go over? What matters it if the coupling box on the main is one foot outside of the house line? The cable is pliable and all these obstacles can be readily overcome. Avoid sharp turns.

With this method there is no tubing to be cut; no short pieces are needed; no elbow-pieces are to be laid; no elbow joints, no elbow boxes; no coupling joints, and no coupling boxes are required. Then think of the saving in the use of that expensive necessity—compound. Only one joint is to be made, namely, the connection of the cable to the main; no salary for a tester. The cable is tested on the reel, this answering for about 20 services. Cable is cheaper than tubing per foot; cable couplings are cheaper than joints. The T-box is put on and you have saved dollars in material and time. As well as locating the work for the street plans, it will be found to be good business policy, as an item of reference from both a financial and engineering standpoint, to adopt some system of recording the work done, with the expense attached. The Philadelphia company uses the following form:

Order Ticket for Services and Meters.

Order No.......................... Page............
Name..
Premises..
Ordered by..............................Date..............189
Order...
What done...
Done by.................................Date..............189
Foreman.
Permit....................Meter.............................

T-Box.....................Wire..............................
Service End Box...........Miscellaneous.....................
Clamps....................Labor.............................
Miscellaneous...
Labor...
Total...
Credit Material Returned....................................
Net Cost..
Entered by..

Be sure to designate the size of the service. It will be a great guide when the subscriber wishes an increase in light or power. You will then be able to tell at a glance if the service will carry the increased load. It is always well to allow for such an increase as it is sure to come in some degree at an early date.

In two and a half years' experience in the practical use of this cable, under all existing circumstances, the company has yet to find the first trouble of any kind. When it is borne in mind that over 500 services are thus connected, it is a record hard to beat. To Prof. Wm. D. Marks, the president and supervising engineer of the Philadelphia Edison Company, is due the adoption of this cable.

INSULATED ELECTRIC CONDUCTORS.[1]—V.

BY

James Bowstead Williams M.D.

Chap. IV.

If we were to make a list of *all* the substances which are specified and claimed in letters patent for insulating material issued in the United States and England, we would find the number of such substances to be between two and three hundred; and this list would include almost everything that could be wrapped around, or secured to, electric conductors. Many of these substances are utterly worthless as insulating media, for they possess no insulating properties of themselves, nor can they be used to any advantage in combinations with good insulating material; and why they were secured by patents the inventors or discoverers alone know.

The number of really useful insulating substances is smaller than is generally supposed, seeing that we have such a large number to select from; but that the reader may know what is generally used for insulating purposes the following list has been compiled, which includes substances from which the different kinds of insulating material are made. It may be added, with reference to some of the substances included, that in one or two instances it has not been deemed necessary to enlarge in detail on every one of them.

The arrangement of the substances under the different headings is made simply for convenience of reference.

Gums.—India-rubber, gutta-percha and balata.

Resinous Bodies.—Colophony, shellac, Venice turpentine, copal, dammar, pitch, turpentine, amber, mastic, sandarac, animé and kowrie.

Vegetable Oils and their Products.—Linseed, cotton-seed, castor, olive and rosin oils; oxidized oils, sulphurized oils and elastikon.

Waxes.—Beeswax, paraffine, ozokerite and spermaceti.

Mineral Oils.—Petroleum, paraffine, and liquid paraffine.

Petroleum Products.—Asphalt, bitumen, maltha, residue and redistillates of residue.

Tars.—Coal and wood.

Fibrous Material.—Silk, cotton, jute, paper, parchment, cellulose and asbestos.

Mineral Substances.—Mica, silica and silicates, glass, kaolin, chalk, magnesia, talc, plaster, lime, sulphur and sulphides, oxides of lead and zinc, and asbestos.

Miscellaneous.—Lampblack, graphite, leatheroid, vulcanized fibre, liquid glass, stearine, glycerine, hard rubber, coal tar asphalt and celluloid.

In the present series of articles information relating to the origin, general properties, etc., of the substances enumerated in the foregoing list will not be given, as such information can be obtained from encyclopedias and other works of reference. The writer will, therefore, confine himself to a discussion of matters of practical importance worthy of the closest attention and study of the electrical engineer, but not to be found in any of the books. In other words, he proposes that these articles shall be a narrative of investigation and not a mere compilation of data already recorded and within everybody's reach.

India-Rubber.—This is one of the most important insulating bodies known; in many respects it is superior to all others for general purposes of insulation in that—1. It has a very high specific resistance. 2. It can be used alone to insulate all classes of electric conductors. 3. It can be used to form useful combinations with all other good insulating material. 4. When properly used it is to a high degree permanent and anhygroscopic. 5. It retains its insulating properties at comparatively high temperatures. 6. It does not readily soften by heat.

All rubber consists of two distinct bodies or modifications, both of which are identical and similar as regards their general properties. One of these modifications is hard or fibrous, and the other soft and viscous. It is this latter which causes freshly-cut pieces of rubber to unite when placed in contact with each other, and also which is vulcanized, or cured, by the action of sulphur.

As stated in a previous article, the best rubber for insulating purposes is the Para (from South America). If a perfect "biscuit"—so called from the form of the imported lumps—of this rubber be examined, by dissection, it will be found to consist of several distinct layers, closely adhering to each other, and of different colors. The color of the layers varies with the position of the layers in the mass, and depends upon the age of the rubber and also upon the care taken to protect the milky juice of the trees while it is being coagulated to form the biscuits.

The color of the outer and exposed layers is usually a dirty brown, and each succeeding layer has a lighter color until the inner and protected layers are reached, which have a milky-white color. This white rubber is the pure unoxidized coagulated milk of the trees, and its specific resistance is much higher than that of the darker colored and oxidized rubber of the outer layers. But if this pure-white rubber is left exposed to air and light it gradually gets darker colored (oxidized) until it has the brown color of the outer layers of the original lump; and as its color changes its resistance diminishes. If this oxidization continues, the rubber finally deteriorates to a brittle resinous mass, and it is then useless for electric insulation.

All rubber being porous and cellular, its porosity is increased by subjecting it to the washing process, which is done to remove dirt and other foreign matters; so that washed rubber, unless protected, will absorb oxygen and moisture and deteriorate faster than the unwashed.

When used for insulating purposes, rubber should *always* be combined with a "preservative" material which does not, of itself, readily oxidize. Pure paraffine wax is a good preservative, but unless it is combined with a soft resinous body—which acts as a cement for the rubber and paraffine,—it is very apt to separate from the rubber, and almost always does separate from it, when the vulcanized product is heated. Beeswax also acts as a preservative, when used in the same manner as paraffine. Either paraffine or beeswax and resin can be combined with rubber by first melting the wax and resin together, and then filling the pores of the rubber with this material by means of heat and a vacuum; or by melting together, and then "working" this compound with the rubber on hot mixing rolls; or by dissolving the three ingredients in a volatile solvent, mixing the solutions, and then distilling the solvent. By employing the latter process all danger of overheating the materials is avoided. After the rubber and preservative are combined the combination is ready for the incorporation therewith of other ingredients, on hot mixing rolls. If much paraffine is used as a preservative the compound is easily softened by heat, and special precautions have to be taken to keep wires concentric with the compound during vulcanization.

Inert powders, such as chalk, etc., when combined with rubber do not tend to preserve it, like the waxes. Combining rubber with one or more powdered substances simply distributes the rubber throughout the mass; there is nothing present to preserve it, and as soon as it deteriorates the mass gets full of cracks and becomes worthless.

Rubber should never be used unless *absolutely* dry. All rubber, before and immediately after washing, contains more or less moisture; in some cases, as much as one-fourth of the entire weight. One cannot be *too* careful to have the rubber dry; and, if possible, *all* rubber should be kept, after washing, in a warm dry room, free from light and dust, for several months, or else be kept exposed, when in very thin sheets, to a current of hot dry air for several days, before it is used. If the rubber be free from moisture, not only will the dielectrics of which it forms a principal ingredient have a much higher insulation resistance, but the dielectric itself, if properly used, will be much less liable to subsequent deterioration than if the rubber contained but a small amount of moisture.

---

[1] *Copyrighted 1891, by James B. Williams, M. D. All rights reserved.*

Rubber *can* be kept pure and dry, after washing, for many years. The writer has used Para rubber which had been washed over five years previously, yet the color of the exposed portions of the washed sheets remained a reddish brown and that of the unexposed portions a clear white. The specific resistance of this rubber was phenomenal, when compared with the ordinary washed Para, its elasticity was greater, and its consistency firmer.

If the milk of the rubber trees were imported in opaque bottles or other vessels instead of in the coagulated form, the milk could be coagulated by the manufacturer of insulated wires and cables, and any foreign matters, such as dirt, bits of bark, etc., could be removed by dissolving the dry coagulated mass and filtering it. The resulting product would then be pure and unoxidized, and it would have all the properties of the pure gum, which are far different from those of the ordinary spongy, washed material.

Para rubber loses from 10 to 20 per cent. of its weight by cleaning. This loss consists of moisture, dirt, stones, bark, etc. All of these substances being detrimental to insulation, it is necessary that the rubber used for insulation should be more thoroughly cleansed than that used in the manufacture of rubber goods. Small pieces of wood or stone in a rubber dielectric may indirectly cause the loss of a costly cable.

Vulcanizing rubber does not increase its specific resistance—under certain circumstances it may diminish it—but the vulcanized material will not crack, when bent, at low temperatures, nor soften at high temperatures, as readily as the unvulcanized material.

The amount of rubber necessary to impart flexibility to vulcanized dielectrics depends upon the materials with which it is incorporated, and can be ascertained only by experiment. Most of the vulcanized dielectrics now in use contain from 25 to 40 per cent. of rubber. But there are "vulcanized" dielectrics which are tough and flexible and yet contain little or no rubber.

Ozone rapidly attacks and destroys rubber. As ozone is always formed whenever a brush discharge occurs in air, all exposed rubber-covered wires in the immediate vicinity of a brush discharge soon become useless. This brush discharge may occur between the bare wires of two neighboring conductors or even between two insulated conductors, if there are any cracks or other breaks in the dielectrics. An ozone-producing discharge may also take place over the surface of hard rubber or other insulating material if such material has minute particles of conducting matter thickly scattered over, and retained upon, its surface.

Several solvents of rubber are given in "the books," but many of these, when evaporated from the rubber solutions, do not leave the rubber in its original condition. Bisulphide of carbon, with a small per cent. of absolute alcohol added (to absorb any moisture in the rubber), is the best and cheapest solvent to use in the manufacture of insulated conductors, notwithstanding its first cost, because it can be recovered, with practically no loss, after it has been used to deposit a thin layer of rubber either upon a tinned wire or upon a layer of insulating material insoluble in the solvent. A thin layer thus applied adheres much more firmly to whatever is beneath it than if the layer were formed of a thin strip wound upon the underlying material.

Any one wishing to examine pure rubber can obtain it by evaporating the juice of the common milkweed which contains it.

Further items of importance concerning rubber will be mentioned under other headings.

NOTE ON LIGHTNING PROTECTORS AND NON-ARCING METALS.

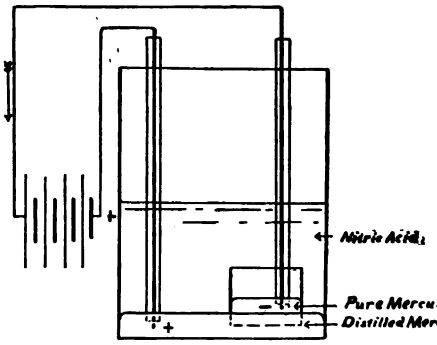
BY

A. K. McCay.

Two of the non-arcing metals, zinc and mercury, present a very curious phenomenon when combined. On investigation of the conductivity of either metal at different temperatures it will be found that both zinc and mercury follow Matthiessen's formula, $c = 100 - 0.37647\,t + 0.0008340\,t^2 +$ etc. Several years ago while carrying on some experiments under Prof. Helmholtz, in Berlin, he proposed to me during a lull in other work, that I should investigate the resistance of zinc and mercury combined in different proportions. This experiment I undertook.

To obtain pure zinc I distilled commercial zinc, and, after treating it with special chemical processes I tested the same by spectroscopic analysis, using one of Rowland's ruled glasses which give lines whose wave lengths were measured and from which the purity of the zinc was undeniably demonstrated.

When the question of pure mercury came up, I found that even after distilling and treating by chemicals, I still did not have pure mercury. After consulting various authorities, I asked Prof. Helmholtz and he suggested the following method, which I shall briefly describe: After obtaining the finest mercury by distillation and removing, as far as possible, all foreign metals, I placed it in a glass jar as shown in the accompanying diagram. I then poured concentrated nitric acid on top of the same. Then taking a small glass cup I placed it on top of the mercury and allowed it to float. Then I placed the platinum wire which made the positive (+) pole of my battery, consisting of some four Bunsen cells in multiple, in the mercury beneath the acid, having the wire leading thereto carefully insulated from the acid by a glass tube. The negative pole was placed in the small cup, which was entirely covered with acid. In this way in about one week's precipitation I procured one-eighth pound of mercury, which was ample for my purpose.



METHOD OF OBTAINING PURE MERCURY.

Having obtained the mercury and zinc, I made my amalgams, and found that in every case they decreased in resistance, which is exactly opposite to what one would be inclined to expect. Mr. Wurts in his recent Institute paper says he found that the paste made from zinc and mercury was an arcing metal, while pure zinc and mercury were non-arcing. It appears to me, then, that Mr. Wurts' theory of the action of non-arcing metals, viz., that a vapor of high resistance is momentarily projected between the poles, breaking the arc, is correct. The resistance of zinc and mercury both increase with the temperature, and at the high temperature of an electric arc must be very high, but if the amalgam decreases with high temperatures then it follows very closely that this paste would be non-arcing. This agrees with Mr. Wurts' results.

Press of other work compelled me to abandon the investigation, and I had not recalled it till I heard of Mr. Wurts' exhaustive and able paper. The subject is very interesting and instructive, and I hope he will pursue his investigations further, particularly studying the arc in a vacuum.

ARC LIGHT WIRING.

BY

S. H. Sharpsteen

Mr. W. B. Rommel's comments[1] on my article[2] on arc light wiring may mislead parties who are not very well versed in the electric lighting business. Persons conversant with the business will see at once the point at issue, and if they have not thought over the system previous to seeing my article, will understand that it is good under the circumstances which I mentioned.

In the average town the commercial lamps are very nearly all on one street and short streets off from it. The municipal lamps are, as a rule, two blocks apart. Mr. Rommel seems to think that the main street cannot be without the city wire for a time to make a loop and come back two or three blocks below or above. He speaks of putting one side of the street circuit on one street and the other side on another, or down one street and up another. Such a town would have to be made up of two long streets with short ones intersecting and in this long and narrow town the three-wire system of arc wiring is at its best as it is cheaper to loop down to the lamps on the second street at every block than it is to build another pole line. If the town is deeper than three streets the looping has got to be done anyhow.

Mr. Rommel speaks of the arc lamps that he has installed running the full current through the magnet coils after the lamp is cut out and this current passing through the magnet coils interfering with the adjustment of the lamp, etc. Will Mr. Rommel please give us the name of the arc lamp that he speaks of?

Mr. C. G. Young in his article[3] puts the matter in the proper light to lead a person into the pros and cons. When I wrote the article I had in mind small stations of from 50 to 80 arc lamps. Stations from which a large number of street lamps are worked have no particular use for this system on their street light circuits at any rate. To get the economy down directly to dollars and cents, as Mr. Young speaks of, was not the point I had in view either.

In the installation of a plant for public lighting one of the very prominent questions that suggest itself is, "How can we avoid having the commercial lamps out?" To get good prices, good service must be rendered. A commercial arc circuit that is out oftener than once a year is not a success; once in five years I consider bad if it be out for any length of time. It is understood here that what is meant by being out is not to have the light when it is customary.

Another question is, can a street circuit for street lighting be as proof against being "open" as a commercial, or, better, an inside, commercial circuit? This question, I think, is very easily answered in the negative. An inside commercial circuit put up by the right man will never get "open" we may say, but of the outside circuit, suspended in various ways, full of loops running to lamps in centre of streets and to all kinds of fixtures, the wires are liable to get broken or worked loose. A plant could not be installed for me and have the inside commercial lamps on circuits with street lamps, as street lamps are now installed. Again, when the street lamps are in circuit with the commercials, if they be of equal number and equally proof against open circuits, the commercials have double the chance of being out from open circuit. There are a great many towns where they have from 50 to 80 arc lamps very nearly equally divided between municipal and commercial or inside and outside lamps. For good service at times during the year the inside lamps have to be started as early as 3.30 and 4 p. m.; 5.30 would be early enough for the street lights at the time mentioned above. Some towns use their street lights until 12 and 1 a. m. only. Twenty-five or forty arc lamps worked for 1½ hour is quite an item, and with the people that have no street lights after 1 a. m., the run from 3.30 p. m. until 1 a. m. is too long for single lamps with $\frac{7}{16}$ carbons, which it is economy to use.

From 10 years' experience in connection with both large and small stations, I conclude that if there are to be worked 50 or up to 80 arc lamps about equally divided between outside and inside lamps, I should want the inside lamps on a separate circuit. If there are to be two circuits it is evident that it is cheaper to put commercials on one side, street lights on the other and at the last commercial or the last street lamp connect on a third wire and run the same to the station.

It may seem a little obscure to some what I mean by the outside and inside lamps being on separate circuits when in fact they are both on one circuit. The point is here: With the three wires at one's service, if the arc circuit goes out from outside trouble the person in attendance can close the inside lamp loop through the third wire and if the trouble is on the other leg, his commercials will come up at once.

THE ENERGY CONSUMED IN ARC LAMPS UNDER VARIOUS CONDITIONS.

BY

Frank B. Widmayer

In regard to the discussions in The Electrical Engineer, on "Economy in Arc Light Wiring," and referring especially to Mr. Rommel's article in the issue of March 30, I give below the results of some experiments I made on two well-known arc single-carbon rack lamps, one a 10-ampere 2,000 c. p. lamp and the other a 4-ampere 800 c. p. lamp. The readings for voltage were taken across the binding posts and the average of a number of readings taken is given. The current readings were taken in the usual way by ammeter; the instruments used were the well-known Weston ammeter and voltmeter.

The object of these experiments was to determine three things, namely:

First, energy in watts required to run the lamp under normal conditions.

Second, energy in watts consumed or wasted in lamp after carbons were consumed and dropped together and so cut out or burnt out, the current going through lamp, coils, and carbon stumps.

Third, energy in watts consumed in lamp after being cut out by the ordinary automatic cut-out, consisting of two small magnets in circuit, one of very fine wire in shunt and one of coarse wire in the main circuit; when the lamp is cut out, all the current flows through the small coarse wire magnet and armature which short-circuits the lamp between the two binding posts, with no current in the carbons, main line spools or shunts.

The following were obtained on the 10-ampere lamp:

Experiment No. 1.—10-Ampere Lamp.

First Case.—Burning 48 volts and 10 amperes. 480 watts consumed.

---

[1] The Electrical Engineer, March 30.
[2] The Electrical Engineer, March 16.
[3] The Electrical Engineer, March 30.

Second Case.—Loss in watts, or drop of potential in lamp with carbons together, current going through carbon stumps, spools, etc. Drop of E. M. F., 4 volts; current 10 amperes, thus, 40 watts consumed or lost in heating carbons, spools, etc.

Third Case.—Energy lost in watts through heating of cut-out coil. Drop, 2 (volts) × 10 amperes = 20 watts.

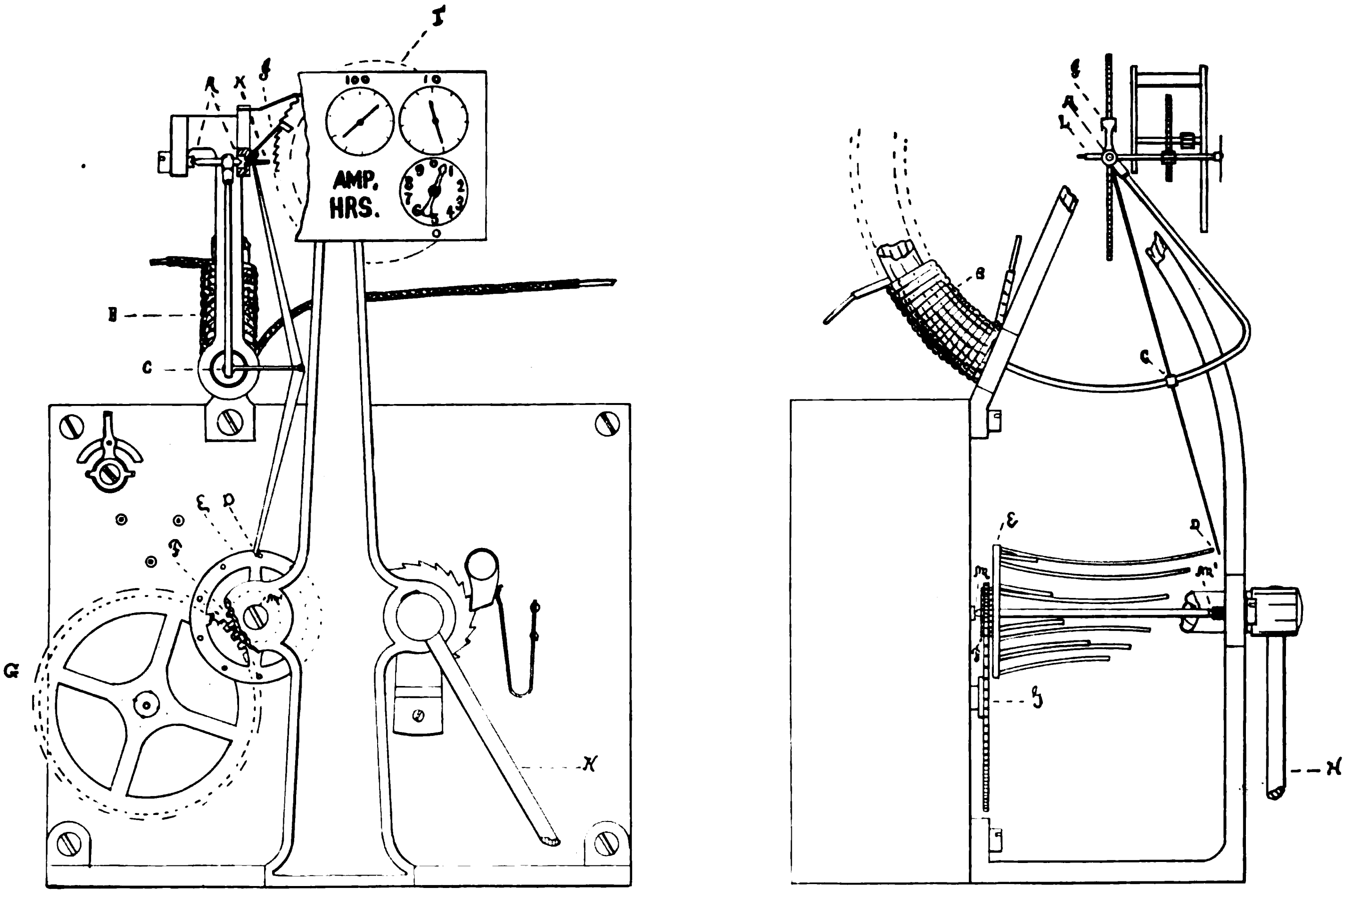
EXPERIMENT No. 2.—4-AMPERE LAMP.

First Case.—E. M. F., 52 volts; current, 4 amperes. 52 × 4 = 208 watts consumed in running lamp.

Second Case.—E. M. F., 4 volts; current, 4 amperes. 4 × 4 = 16 watts lost in heating carbon stumps, spools, etc.

Third Case.—E. M. F., 1 volt; current = 4 amperes. 1 × 4 = 4 watts lost in cut-out.

I think the most economical method of wiring arc lamps, especially in large cities where subway rentals are very high, is to run both the commercial and city lights on the same circuit and by having a good lamp, that is, one having the ordinary cut-out and a special cut-out, such as is described below—there would be no trouble with the service. Let us assume that the city lamps are all-night lamps and the commercial are 7-hour lamps. Start both at the same time, trim the commercial lamps so that they will run the time required and will drop out, that is, the carbons will drop together and close the circuit through the lamp. Have a small pin fixed on the carbon rod in the lamp case; this pin when the rod drops, say ¼ to ⅜ inch, will trip a lever which will short-circuit the lamp across the terminals and so directly cut the lamp out of circuit.



FIGS. 1 AND 2.—FRONT AND SIDE VIEW OF MECHANISM OF THE PILKINGTON-WHITE METER.

If this method were used, I believe there would be a saving of from 30 to 40 watts on each 10-ampere lamp so equipped. Another method, but not as good as the one just described would be to have the pin move the ordinary cut-out lever till it makes contact with the magnet and coarse wire coil; in this case the current would only flow through the coarse magnet in cut-out and so short-circuit the lamp in the usual way.

THE PILKINGTON-WHITE METER.

BY

Herbert M. Pilkington

CONFUCIUS said many centuries ago, "Man believes in his heart only what he sees with his eye." Human nature has not changed—customers want to "see the wheels go round" and to gratify this laudable desire has been the ambition of Mr. R. S. White and myself. The accompanying illustration of size No. 1, 5 amperes, will enable the reader to see how we have done it.

It will be observed that we have employed the simplest and best known elements in use. Every one knows what a gravity ammeter with the minimum of iron can do and millions of clocks in daily use bear their own testimony. A reliable mechanical connection between these elements, free as possible from complication, was our aim—we worked it down to one moving part and stopped for obvious reasons.

Fig. 1 is a front view of the mechanism and Fig. 2 a side view, while Figs. 3 and 4 show the meter as it actually appears. A 40-day clock in dust-proof case drives by gear G and pinion F, the disc E which carries curved pins and D which disc is mounted on a phosphor bronze shaft centered at M and M^1 Fig. 2. At B is an ammeter solenoid; swinging from centres A is its light soft iron core carrying at C a fixed bracket at the outer end of which is freely pivoted a light lever. This lever is forked at the upper end to embrace the steady pin K, and has a pawl J engaging the ratchet wheel I of a dial train. The action is as follows:

The movement is wound by removable crank key H and for 40 days turns disc E around at the rate of five turns an hour.

In this disc is set a pin for each half ampere of the meter's capacity; making in this case ten pins. These are of various lengths corresponding to the calibration of the instrument.

When, say, half an ampere is passing on the coil B, the ammeter moves and carries the lever to a position where it will be struck by the first pin D, Fig. 2, once in every revolution of disc E.

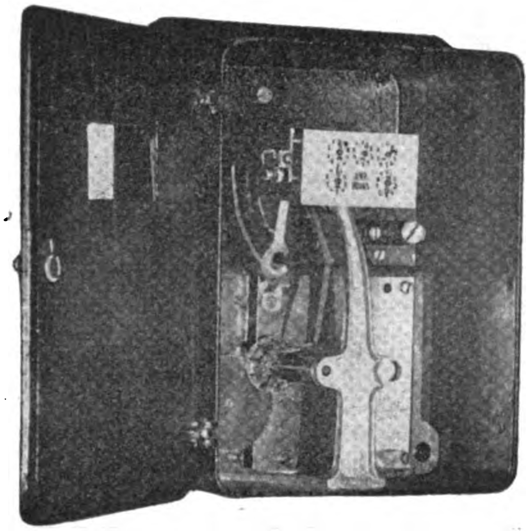


FIG. 3.—THE PILKINGTON-WHITE METER.

For every additional half ampere the arm will move over further and another pin will come into action, until at five amperes the full number come into play.

It will be readily seen that the lever by being pivoted on bracket C and guided at centre K forms an integral part of the ammeter core, at the same time possessing its own plane of rotation at right angles to the latter. Therefore when the pin D moving to the left carries the lower end of the lever in the same direction, the upper end, by pawl J, advances the ratched wheel I a distance of one tooth, then D releases the lever and it drops by gravity into position to engage the next pin. Thus at five amperes the lever will transmit to the wheel ten impulses per revolution of disc or 50 per hour. This wheel has 100 teeth and is geared even with the unit's dial, so 50 impulses mean half a revolution of unit's dial or five ampere hours. The lever being retained only a few seconds by each pin, is always ready to take up a new position as the load is varied. Supposing the load to drop to one ampere, the ammeter falls back, and two pins only will engage the lever, recording thereby 10 teeth in an hour, or one ampere per hour.

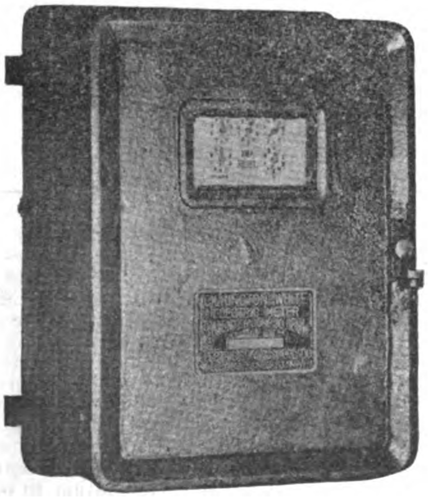

FIG. 4.—THE PILKINGTON-WHITE METER.

This meter is suited to any circuits, introduces no drop, requires no electrical power to run it, and is not affected by short-circuits. The case is iron, insuring freedom from outside influence, and the current may be reversed, as it frequently is in practice, without affecting the reading.

The different capacities all go in the same-sized case, a very desirable feature where numbers of them are handled. This meter has been patented in the United States, Canada, Great Britain, Germany, France and Belgium.

RULES FOR TESTING TELEGRAPH LINES.

BY

F. W. Jones

IN a telegraph company a great desideratum has always been a system of electrical testing that was adapted to the capacity of managers and chief operators having direct charge of the circuits. Heretofore tests have been usually made by the Morse relay and key, and a galvanometer only called in use in a desultory way.

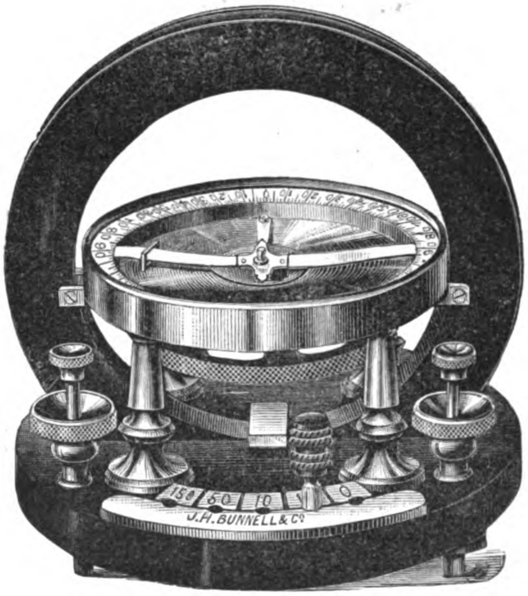

FIG. 1.—TANGENT GALVANOMETER.

The following system that is at once practical and serviceable has been adopted by the Postal Telegraph-Cable Company at all of its principal testing stations, and so expert are the various chief operators becoming in handling the simple apparatus that a vast saving in time and expense has resulted in the repairs of breaks and crosses in the main lines by the location of these troubles through electrical tests; as a repairman is sent directly to the spot. Whereas heretofore a trouble was located between two stations and two repairman, one from each station, were sent to meet each other.

A combined Wheatstone bridge and galvanometer, Fig. 2, is used for the location of crosses and grounds where accurate measurements are necessary. Once each month during a very dry day each station supplied with this instrument makes a careful loop test of all the main line wires within its jurisdiction and forwards the results to the electrician's office at New York. This is to enable the electrician to notice any undue deterioration of the wires.

For insulation and battery tests the tangent galvanometer, Fig. 1, is used, according to rules given below. By the aid of this instrument the chief operator goes rapidly over his wires every morning and notes the deflection upon the galvanometer of 100 volts due to the leakage between the testing station and the farthest limit of its jurisdiction. Referring to the table of degrees the ohms are directly obtained. Should the wire not measure up to its usual resistance, according to the state of the weather then prevailing, the chief operator has the wire opened at the various intermediate offices (if any) and notes the deflections respectively, thereby ascertaining between which two the leakage exists. It is needless to say that compared with this method the old-style relay and key system is very inefficient and crude.

The main batteries are also tested by the tangent galvanometer for internal resistance, which is a good indication of their condition. A special rheostat for use in shunting the tangent galvanometer and for using in the circuit when measuring the internal resistance of the batteries, has the following coils in ohms: 1, 2, 3, 4, 10, 20, 30, 40, 100, 200, 300, 400, 1000, infinity; correct within one-half of one per cent., and the wire coarse enough to carry any battery currents without unduly heating. Should any insulation tests be required on the lines, more exact than can be made with the tangent galvanometer, the Wheatstone bridge is resorted to and the sides multiplied 10 to 100 or 10 to 1,000 in the usual way. More delicate tests of underground or submarine cables are made by more appropriate apparatus furnished by the electrician's office.

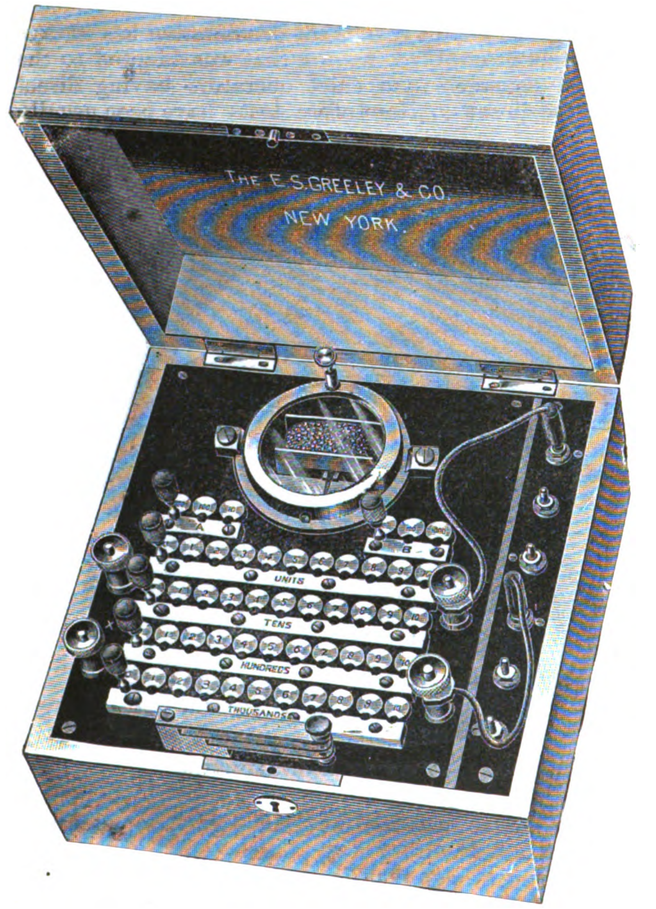

FIG. 2.—WHEATSTONE BRIDGE AND GALVANOMETER.

RULES FOR MEASURING INSULATION FOR SUPERINTENDENTS AND MANAGERS.

The use of the tangent galvanometer for insulation tests of line wires may be facilitated by observing these rules in connection with a table of degrees furnished herewith.

Taking the Constant.

If a battery station, use 100 cells of Callaud battery. (Where dynamos are in use, the positive and negative potential nearest to 100 volts may be employed, care being taken to keep them as nearly equal as possible.) Connect the battery to the tangent galvanometer through 10,000 ohms and place a resistance as a shunt across the terminal of the galvanometer, using the 200-ohm coil, so that part of the current flows through the galvanometer and part through the shunt. Set the galvanometer away from all working electromagnets, with the pointer at zero, and adjust the resistance in the shunt until the pointer is opposite 45 degrees (on the degree scale, not on the tangent scale.) Then remove the 10,000 ohms, ground one pole of the battery and connect the line through the galvanometer to the other pole of the battery, leaving the shunt undisturbed. Note the deflection obtained, say, 24 degrees. Reverse the battery and again note the deflection, say, 32 degrees. Take the tangent number 35.5 opposite 32 in the table and add thereto the tangent number 25.5 opposite 24 degrees, and divide this sum, 61, by 2. Look in the tangent column for the nearest number to 30.5, the quotient obtained. The number 30, being the nearest number so found, will stand opposite the resistance, 18,807 ohms, which is sufficiently exact for purposes of insulation measurements. When the deflections obtained from positive and negative poles are equal, the resistance will be found directly opposite the degree in the table.

POSTAL TELEGRAPH CABLE COMPANY—TABLE FOR INSULATION MEASUREMENTS.

Deflection.		Insulation ohms.	Deflection.		Insulation ohms.

31	34	16643	78	269	2126
32	35.5	16003	79	294	1944
33	37	15399	80	326	1763
34	38.5	14826	81	360	1584
35	40	14281	82	406	1405
36	41.5	13764	83	465	1228
37	43	13270	84	543	1051
38	44	12799	85	653	875
39	46	12349	86	817	699
40	48	11918	87	1090	524
41	49	11504	88	1636	349
42	51	11106	89	3273	175
43	53	10724			

Should the insulation be so high as to produce less than one degree deflection, remove the shunt and read the degrees of deflection without it and multiply the corresponding ohms in the table by the multiplying power of the shunt, which can be found as follows: Measure the resistance of shunt and add it to the resistance of galvanometer, and divide this sum by the resistance of the shunt. For example, calling galvanometer 200 and shunt 80 ohms, then their sum, 280, divided by the shunt, 80, gives 3.5 as the multiplying power of the shunt of the particular coil in use. If a wire tested without the shunt, as above, gives a reading of 28 degrees on both poles, then 18,807 ohms, multiplied by 3.5, or 65,824 ohms, is the required resistance. A change of battery cells, or shunt resistance, will require a new calculation to obtain the power of the shunt.

Example of a test by station A to obtain the insulation resistance of a wire from A to B, 20 miles, and from B to C, 20 miles, total distance 40 miles.

With C open, A records a deflection of 20 degrees; with B open, a deflection of 10 degrees; then the insulation from A to B is 56,713 ohms, from A to C is 27,445 ohms. To calculate the insulation between B and C, note the tangents of the two deflections, thus:

20 degrees = 21
10 degrees = 10

and opposite 11 degrees (the difference between 10 and 21) we find 51,466 ohms. To obtain the insulation per mile, multiply the total insulation by the number of miles; thus total insulation from A to B, 20 miles, equals 56,718 ohms, making an average mileage of 1.184 megohm.

The conductivity measurements are made by placing the 200-ohm coil of the galvanometer in the bridge. Care must be taken not to use a large battery through a small resistance in the bridge, hence when the unknown resistance is between 1 and 100 ohms, the A and B sides of bridge should be 10 ohms and not over two cells of Callaud battery. Between 100 and 1,000, A and B 100 ohms; not over 20 cells. Over 1,000 ohms A and B 1,000 ohms; not over 100 cells. The battery key only to be depressed long enough to secure a steady balance of needle at zero.

All line wires which have been designated should be regularly measured for insulation and conductivity once a month and the results forwarded, on blanks supplied for the purpose, to the electrician's office.

Battery Tests.

All main batteries should be tested at the switch every morning, to see that they are in good order. Use the coil marked 0 and introduce resistance until the deflection on the tangent scale of the galvanometer is reduced one-half, viz., if needle points to 20 degrees bring it down to 10 degrees by inserting resistance. This resistance will be equal to the internal resistance of the battery. No office must be without a hydrometer and batteries must not be diluted with water below 15 degrees nor allowed to exceed 35 degrees. Oil should be used to prevent evaporation; the stands kept scrupulously clean and dry; the connections all firmly screwed up and the best gutta-percha wires used upon the coppers to prevent a short-circuit within the cell. It should be borne in mind that the battery is the most important part of the circuit and needs the very best attention.

F. W. Jones, Electrician.

THE RAPID CALCULATION OF MAGNETO-MOTIVE FORCES.

The mode of calculation adopted up to the present for the determination of the magneto-motive forces necessary to maintain a given magnetic flow in a circuit is generally somewhat complicated and laborious, for it takes into account permeabilities, magnetic resistances and magnetizing forces in C. G. S. units, whereas what we want to know practically is the magneto-motive force in ampere turns. M. Steinmetz's recent study of the law of hysteresis, writes M. Hospitalier in *L'Industrie Electrique*, has suggested to us the idea of simplifying these calculations by drawing up a table of the magnetizing forces necessary to produce a given induction in a magnetic circuit, the nature of which is known (air, soft iron, cast iron, etc.). This table gives the values of the magnetizing forces in ampere turns per centimetre, so that in order to determine in ampere turns the magneto-motive force, F, necessary to produce a given induction B, in a circuit of given length, l (in centimetres), all we have to do is to multiply the value of the magnetizing force, K, indicated in the subjoined table by the length of the circuit, l, in centimetres.

$$F = K\,l.$$

TABLE OF MAGNETIZING FORCES AS A FUNCTION OF THE INDUCTION.

Induction.	Magnetizing force K. In ampere turns per centimetre.		
B	Air.	Cast Iron.	Soft Iron.
1,000	800	....	..
2,000	1,600	....	....
3,000	2,400	....	....
4,000	3,200	4	....
5,000	4,000	8	1.6
6 000	4.800	17.2	1.95
7,000	5,600	33.6	2.3
8,000	6,400	64.0	2.7
9,000	7,200	101.6	3.2
10,000	8,000	150.4	4.0
11,000	...	233.6	5.2
12,000	....	....	6.8
13,000	....	....	9.6
14,000	...	....	13 6
15,000	....	....	22.8
16 000	....	....	41.6
17,000	....	....	84.0
18,000	....	....	160.0
19,000	....	...	280.0
20,000	....	....	....

Example.—We will take a dynamo, the air gap of which throughout its length is 2 centimetres thick (B = 3,000), the cast-iron inductors are 50 centimetres long (B = 8,000); and the soft iron armature is 40 centimetres long (B = 15,000); we have to determine the total magneto-motive force. We have:

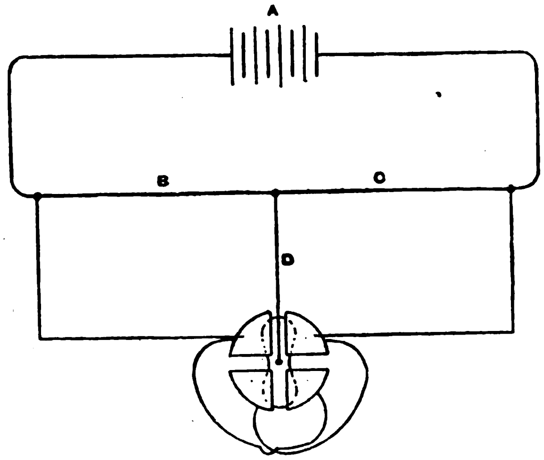
	B.	K.	l.	F.	
For the air gap...............	3,000	2,400	2	4,800	ampere turns.
For the field magnets........	8,000	64	50	3,200	"
For the armature...........	15,000	22.8	40	912	"
Total..................				8,912	

The magnetic constants determined by Dr. J. Hopkinson, when presented under this new form, give at once the numerical values of the magneto-motive forces necessary to overcome the individual magnetic resistances of each part of the circuit, and also show those upon which which we can act most effectively to modify the properties of the apparatus in view of a given result.

We think it will be of service to constructors of dynamos, motors, and transformers, to publish the above table, which will facilitate their calculations, as well as the sketching out of the characteristics as a function of the ampere turns of excitation.

THE COMPARISON OF VERY HIGH RESISTANCES.

Major Cardew has recently introduced the following method of comparing very high resistances, such as millions of megohms. Referring to the annexed diagram, A is a battery giving some 100 or 200 volts, B and C are two very high resistances. The quadrants of the electrometer are connected up as shown, the needle being connected to the point between B and C. If B is to be measured, C is altered until the needle comes to zero. It is then clear that the fall of potential over B is equal to that over C, so their resistances are equal. This method will show when two resistances are equal, however high they may be, provided they are low in comparison with the leakage resistance of the electrometer itself.



Comparing Very High Resistances.

MILITARY TELEPHONY.

During the monster military manœuvres which took place last autumn, in the east of France, the telephone was, by order of the Minister of War, made extensive use of. Batteries being inadmissible, magnetic telephones were alone employed; the receiver being fastened to the *képi*, while the transmitter was held in the hand. A combined receiver and transmitter (50 mm. diameter, 400 grammes weight) was also tried. A naked .6 mm. bimetallic wire was used with an earth return. A good earth was made by sticking a bayonet well into the ground. Mounted soldiers connected the earth wire to their horses' bridles, the current going to earth through the horses' hoofs. Two men formed a telephone detachment. One carried the telephones and a rolling drum weighing 2½ kilogrammes and wound with 1,000 metres of conductor; the other had a light bamboo stick, with a hook at the end and another drum of wire. The two men could thus lay 2 kilometres of line. The man with the telephones walked rapidly along unrolling his wire and his comrade followed and placed it as far as possible out of harm's way on branches, hedges, walls and along trenches. In one experiment a 23-kilometre line, with 10 intermediate posts, was laid down in five hours, speech was perfect, and the whole was taken up again in an hour. Earth contacts seemed to have but little influence. During the sham fight of September 7, a 12-kilometer line worked without a moment's interruption, although an entire cavalry division passed over it. The cost of the system need not be an obstacle, 10 kilometres of line, 10 drums, 3 telephones, and 5 bamboo rods only costing 185 francs.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, APRIL 13, 1892. No. 206.

It is often through failures that men learn how to succeed—Chauncey Smith.

RAPID TRANSIT IN BOSTON AND NEW YORK.

THE question of rapid transit in Boston is discussed very exhaustively in the report that has been made by the special commission appointed for the purpose. The difficulties in Boston, from the growth of population and the increase in travel, appear to be the same as they are in New York. Ten years ago, the steam railroads carried in and out 25,000,000 passengers per annum. In the year ended June 30, 1891, that class of travel had swollen to 51,000,000. In 1871, the street railways within the 10-mile circle carried 34,000,000 passengers; in 1881, the number was 68,000,000, and in 1891, it was 136,000,000. Evidently the travel doubles every decade, and the facilities for travel fail to keep pace with the needs of the city.

In order to supplement the great electric system of the West End Company, the Commission proposes an elevated road, reporting many objections to such an underground system as the Greathead tunnel; and it also recommends for the benefit of commuter or suburban travel great union depots on the north and south sides of the city. Both plans are directed to the purpose of making cross-town travel cheap and speedy. It is suggested by the Commission that the motive power for their elevated road would naturally be electricity.

Boston now has its report, and we shall be interested to see what becomes of it. We too in New York have a Commission and a report, but it is hard to see that we are getting along any further. To borrow Thomas Carlyle's phrase, we are merely "marking time", in face of one of the greatest emergencies of city life and growth. Not only is travel up and down town intolerably slow, except by infrequent, crowded expresses, but travel across town above 59th street can hardly be said to exist. All the way from that street up to 125th, there are practically no means of communication by street railways between the great populations of the east and west sides. Yet it would be easy enough to equip electric roads for the purpose, and it would be equally easy to equip up and down electric roads for rapid "rapid transit." Meanwhile, the starting of the cable road on Broadway will be but a slight mitigation of the evils now endured. That is no fault of the cable, for the same is true of the excellent electric service in Boston, and will be true of any surface methods. Swift city travel can only be had by elevated, depressed, or underground roads. Accelerated travel might be had on surface roads, by barring miscellaneous wheeled traffic and by providing bridges or sunken crossings for foot passengers. If that were done, electric cars could at once be speeded up to 15 and 20 miles an hour on ordinary surface street railway tracks, with an immense gain in the convenience of travelers; but no city appears willing to make any such arrangement or concession as that. "Speedways" are not in fashion.

THE GAS EXHIBIT AT THE WORLD'S FAIR.

WE note that our gas friends have been and still are not a little excited over the fact that gas has been slighted as an exhibit for the World's Fair at Chicago. This is a pity, and we can only say that for ourselves we should be glad to see a fine gas display made. Electric lighting has nothing to lose by the contrast, and even if it had, that is no reason why gas should be overlooked. But we must say that some of the gentlemen most prominently connected with the agitation to have gas represented are greatly misinformed on the subject. For example, we find Mr. A. C. Humphreys, of Philadelphia, writing to Director General Davis as follows:

> The gas industry upon the initiative of the World's Fair authorities received no recognition from those authorities. A rival industry, that of electric lighting, not only received recognition, but was assigned a most favorable position for its special exhibition building; and arrangements were made to pay for this building from the funds of the World's Fair organization. This building is designed to be complete and ornamental and covers a ground space of 343 feet by 690.

Now this statement may be well meant, but it is nevertheless all awry. The building in question is *not* intended for, nor will it be devoted to, electric lighting. Its name is "Electricity Building." There will be very little electric light apparatus in it. Probably not one-quarter of the space will be occupied by electric light specialties. Most of the space will be occupied by the telegraph, the telephone, the electric motor, the electric railway, electric bells, clocks, annunciators, burglar alarms, district messenger calls, fire alarms, medical appliances, torpedos, electric mines, batteries, switches, electrical instruments of endless variety, electrical books, electric relics, insulators, wires, cables, subways, cells, interior conduits, cigar lighters, electric filters and a multitude of other things. We think that in providing for this new and vast industry, now growing at such a tremendous rate, the Fair management did very wisely. The electric light is but a small part of the electrical field, and will come in for its share of the building, but no more. The management may use the light for general illumination purposes, but that is not the point in question, any more than their use of electric power during the work of construction. Our sympathies are with the gas interests in their desire for a good exhibit, but it really is a pity they are not better informed.

TAPPING UNDERGROUND MAINS FOR HOUSE SERVICES.

The intelligent observer, watching the developments and changes which have gone on for some time, both in the construction of apparatus and in the operation of central stations, cannot fail to have noticed the fact that in a large measure the day of the so-called "system" has passed. To put it another way, the art has arrived at such a state that numbers of independent workers and thinkers have begun to stamp individuality on their work, which though in many instances, it is true, built upon that of an original "system," nevertheless embodies modifications of distinct value. As a result we notice many differentiations in local practices. An example is brought out in the description, by Mr. Israel, of the method employed by the Edison Company in Philadelphia, in putting in house services from the street mains. Mr. Kortheuer had shown, in a previous issue, how the New York Edison Company effects the same object by means of solid iron tubing resembling in its general nature the tubing employed in the mains; but Mr. Israel points out that many advantages can be gained by the employment of conductors in lead tubes so that they can be bent to conform to irregular passages necessary to reach from the main to the house, thus avoiding all joints, elbows, couplings, etc. An interchange of methods and experiences as here outlined would, we are sure, often prevent needless variations from standard practice and yet add much to the stock of information valuable to central station men. Our columns are always open for any such communications.

THE MARVELS OF THE TROLLEY.

Here is one of the choicest efforts of the prize imbecile who edits plate-matter supplied to the evening papers in the suburban cities :

> **DANGERS OF THE TROLLEY SYSTEM.**
>
> Newark, N. J. April 4.—A furniture truck, drawn by three horses, which became frightened at an electric car on Central avenue, ran away, and dashed madly down the avenue. They ran into one of the poles that support the trolley wire, snapping it like a pipestem, and at the same time knocking a woman down. She was rescued in time to save her from the electric current, which ran along the ground for two blocks.

The careful reader will observe that it was the furniture truck that "ran away;" the horses, being more sensible, were merely "frightened" as they well might be, at the action of the vehicle. The prompt action of the unknown rescuer who dragged the woman from the path of the approaching electric current, which inundated, and doubtless completely submerged, the pavement "for two blocks," cannot be too highly commended. It was obviously one of those cases in which presence of mind was even more important than absence of body.

The Loss in Arc Lamps.

In his admirable paper read at Montreal, last year, Mr. James I. Ayer pointed out, among other things, the great necessity of maintaining accurate current regulation on arc light circuits, and showed how the variation of only a fraction of an ampere might lead to serious loss in the consumption of fuel, etc. But there is another source of loss frequently encountered in the operation of arc lamps, depending upon their construction and the nature of the cut-outs with which they are provided. This is shown by Mr. Widmayer in tests on both ten and four ampere lamps. With the former, the energy consumed in the lamps when the carbons have dropped together and the current thus passes through carbon stumps, spools, etc., may reach nearly ten per cent. of the total energy consumed by the lamp when in full operation; whereas, when completely cut out by the automatic cut-out, the loss may be reduced one-half. In the four-ampere lamp the loss is not quite so large, but still is sufficient to warrant attention to this detail. Attention to apparently small losses of this nature may lead to economies little dreamed of.

Electricity from Gas.

It may be shown by a very simple calculation that the cost by candle power of light as developed by the burning of gas directly in gas burners, compared with the cost per candle power developed in the incandescent lamp from a generator driven by a gas engine is considerably in favor of the latter, and when this comparison is made to apply to the arc light, the economy of the gas engine is self-evident. This fact has already been recognized to some extent by gas companies operating electric light lamps; not a few of them drive their dynamos by gas engines. A recent development in the combination of dynamos with gas engines for domestic purposes is, therefore, worthy of note, and the description which we give of such a combination, on another page, well shows how the general adoption of the multipolar dynamo makes it possible to apply the gas engine direct to the armature shaft without intermediate gearing of any sort.

New Electrical Apparatus.

A distinguished legal writer has observed that instructors of youth should strive "to suppress, with an equal hand, the ebullitions of stupidity, and the coruscations of true genius." It is nevertheless, not easy to say what should be done in some instances, with the ebullitions—or, if you please, the coruscations—of the secular press, when dealing with technical subjects. A transatlantic weekly newspaper in chronicling the various misdeeds of one Mason, who professed among other things, to have found out how to manufacture aluminum at two shillings per pound by a new electrical process, says that he was convicted of having obtained in furtherance of his project under false pretences, "a carsaw voltmeter and a gravity animator" from one firm, and "three animators" from another, not to mention divers other equally curious instruments. Meanwhile the "process" remains a deep mystery.

Wire Determination in Multiple Arc Distribution.

The nature of the work involved in most systems of distribution at constant potential is rarely such that a specific rule can be laid down for designing the plant so as to obtain the greatest economy in wiring, and the judgment of the electrical engineer must enter largely as a factor; but there are, nevertheless, certain general rules which can be applied as a check upon the work. Two rules of this kind, in very simple form, are given by Mr. J. Lester Woodbridge in our issue of this week, and they are of such a character that they can be readily applied.

GEARLESS MOTORS.[1]

BY S. H. SHORT.

AFTER a few remarks introducing his subject, the speaker continued as follows:

We will now take up the matter of the power lost in spur gearing, and see what we can gain in that direction by abandoning gears. When we first took up the subject of a gearless motor, we set about to see how much could be gained in the efficiency of transmission of power by doing away with the gears. I made a very careful and thorough investigation of the losses between the armature pinion and the intermediate gear, and between the intermediate pinion and the axle gear, of a double-reduction motor. I first put a double-reduction motor in good order, eliminating the armature bearing losses, as much as possible, by running the motor for a long time, to wear the bearings down to a good surface. I put my power brake for determining the horse power directly on the armature shaft and ran the motor, delivering different horse powers all the way from zero to its full output—20 h. p. At the same time we measured the electrical horse power which was being put into the motor, and from this we constructed a curve of efficiency of the motor at different loads, which curve is reproduced as the upper curve in Fig. 1. The greatest efficiency reached by this motor was about 70 per cent. at a load of from 14 to 16 h. p. The efficiency at small loads, say at 2 h. p., was something like 50 per cent.; at 4 or 5 h. p. an efficiency of 65 to 70 per cent.

We then took the brake from the armature shaft and replaced it with a well-made armature pinion, allowing it to mesh with a well-made intermediate gear, these gears being cut as nicely and as carefully as possible, so that there would be the least possible loss between the two. Putting the brake on the other end of the intermediate shaft, we again secured the same number of readings of the horse power delivered, after being passed through this one pair of gears, the electrical horse power being indicated carefully at the same time. From the efficiency at different horse powers thus obtained we produced a second curve, which is shown in Fig. 1 as the middle curve in the diagram, and found that the efficiency of this arrangement had fallen considerably. We once more removed the brake and placed the intermediate pinion on the intermediate shaft, allowing it to mesh with the axle gear. The brake was now placed on the axle itself and another set of measurements—the same as those before made, were secured, and a curve of efficiency again plotted, which showed a large loss in the gears, the efficiency at the axle being less than that at the armature by an amount indicated by the two outer curves. The axle results showed that at 14 h. p. delivered by the motor, we obtained an efficiency of 70 per cent. as a maximum when the brake was placed on the armature shaft. When the brake was placed on the intermediate shaft delivering 14 h. p. the efficiency dropped to about 62 per cent. When placed on the axle, the efficiency dropped to a little less than 55 per cent., showing a loss in the gears of some 15 per cent. when delivering 14 h. p. You will find in going over these curves that the loads vary considerably with the speed. Making an efficiency curve of the gears alone at different speeds, you will find the efficiency is very low at heavy loads and slow speeds and rises to its highest at medium speeds and medium loads, falling again when running up to higher speeds. For this reason it is more economical to run a geared motor not too fast or too slow, but at a medium speed. This fact has been established long since in the use of gears in other classes of machinery, and in designing machines where power must be transmitted through gears.

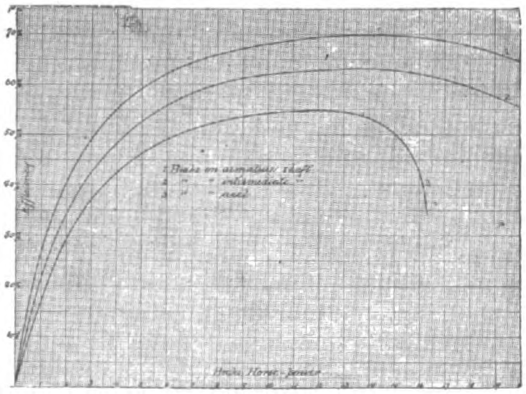

FIG. 1.

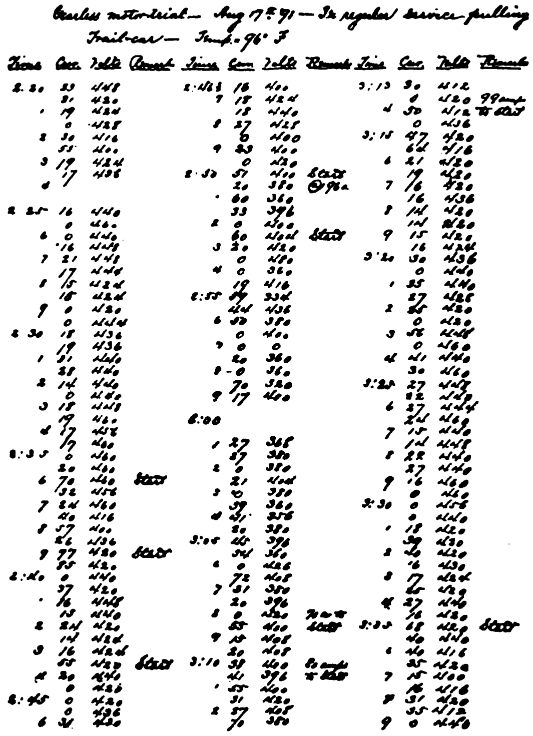
The best possible speed at which gears are to be run, and the relation between pinion and gear, are carefully considered. In the single-reduction motor we regain, we might say, more than half of this loss in efficiency, because the gears are run at a moderate speed. I think that this one feature of gear loss makes it desirable to abandon their use in street car motors if possible. If we can save in practice 15 or more, nearly 20 per cent. of the power consumed in operating a street car motor, by using the gearless instead of the double-reduction type, it is well worth while, as this means the consumption of less coal and the reduction of first cost in the power plant and accessories.

The actual weight carried by a set of wheels on the rails does not seem to affect the joints materially. Old horse cars, even when carrying heavy loads of passengers, do not affect materially the rail joints. Cable cars do not destroy their tracks, no matter how great their loads. Therefore it must be that this heavy weight of the motor carried solidly on the axle is the thing that is breaking down the rail joints on electric lines. This heavy jarring also crystallizes the axles, and we have complaints from all over the country that axles on motor cars are breaking. When we come to examine these breaks we find that the iron has crystallized, and the manufacturers are now endeavoring to overcome this by increasing the size of the axles. With the "gearless" motor, as we now construct it, none of the weight is directly carried on the axle. The wheels, not being very heavy, do not make a heavy blow, but by the time they have reached another portion of the rail the motor falls down against its springs, distributing the blow, as it were, over a considerable length of the rail, thereby preventing serious damage to the rail joint.



Gearless motor trial — Aug 17th 91 — In regular service pulling
Trail-car — Temp. 96° F

FIG. 2.

The question is often asked: How do you obtain the necessary power or tendency to turn the wheels around without using an abnormal amount of current in so doing? It is contended that in a geared motor we have an enormous leverage through the gears. If we had a small armature, the same as is used in the geared motors on the axle, we would not, of course, be able to start the car, or to do the work necessary in moving a loaded car, but we have a large armature placed in a very strong magnetic field, and we have a great many more turns of the same current around the armature, thereby gaining in two ways, a greater leverage because of a larger diameter of armature, and a greater pull at the end of that lever, because of the increased number of turns of wire on the armature and the stronger magnetic field.

We have the advantage in the slow-running motor, of practically doing away with the loss in Foucault currents set up in the armature ring. By designing our motor with a very low resistance of the magnetic circuit, we are able to cut down the wire on the machine so that its resistance is quite low, being only about 2½ ohms. There is another advantage in this slow-speed motor, which is not small; the wear on the commutator is very slight, and the heat produced by the friction of the brushes on the commutator is exceedingly small, making the motor run cool in all its parts. We are obliged, of course, to take advantage of everything that is possible in the construction of the gearless motor, in order to make it small and light enough for street car service.

To answer the question as to how much current is taken by the gearless motor in operating a car, we have prepared readings taken from a car in actual service, drawing a trail car. The current readings, also the pressure readings, were taken every half a minute, and from Fig. 2, a very good idea of the amount of current required can be gained. These readings were taken in August on the East Cleveland Railroad, Cleveland, Ohio. On this road the traffic is very heavy, although the grades are light, but by comparing these results with those obtained from single and double reduction, you will find that there is practically little or no difference between the current readings. The average readings, however, in the test run with the gearless motor, will be considerably lower than those with the geared motor, owing to the fact that we have gotten rid of the gear friction. The gearless motor will coast so easily that on a very slight down grade a car thus equipped will run up to speed, without any current being used, and in making stops the current is shut off from a gearless car long before it is in a geared motor car. These intervals of the use of little or no current as compared with the intervals in which there is little or no current used in a geared motor are very considerable, and represent the extra loss in the gears.

---

[1] Abstract of a paper read before the Chicago Electric Club, March 28, 1892.

We have carefully tested double reduction, single-reduction and gearless cars running on the same track, on roads in Cleveland, Ohio, taking at the same time readings of current and pressure, and we have found that in some cases the single-reduction would require the least amount of current, sometimes the double-reduction and sometimes the gearless, depending upon the number of passengers hauled, stops made, and other things that might come in to consume more or less power; so it is difficult for us to say that there is any difference in actual power consumption between the three classes of machines. The gearless motor is capable of starting loads as quickly as the geared motor, and is capable of starting as heavy a load under similar conditions, and we have a curve shown in Fig. 3 which illustrates the actual horizontal pull of a 20 h. p. gearless motor, mounted on 33-inch wheels. In examining this curve, it will be seen that the horizontal effort in pounds when the car is running 20 miles per hour, is 250. In ordinary street car practice, we find that it requires about 20 pounds per ton to move a load on street car rails. This means that with a horizontal pull of 250 pounds this single motor could move a car weighing 12 tons at the rate of 20 miles per hour, or, as the curve will show, that at 14 miles per hour, the motor has a horizontal pull of 700 pounds, or it will move a load of 35 tons, at the rate of 14 miles per hour on a level track. This curve is not falling off rapidly, certainly not as rapidly as it would with a geared motor, because the loss in the gears begins to increase very rapidly with the heavy loads. You can easily figure from this curve what the motor will do under any conditions of load, grade and speed. The tendency in street car practice is to increase the speed of the cars, and the gearless motor lends itself especially to this end, as we have found that with very rapid speed, geared motors wear out the running parts more rapidly and become very much more expensive to maintain; while the gearless motor can operate with as great economy at the slow pace required in crowded streets, it is also capable of running at a very much higher speed in suburban traffic without the slightest fear of damage to the machine. In this respect it makes a very much more flexible motor than the geared machines.

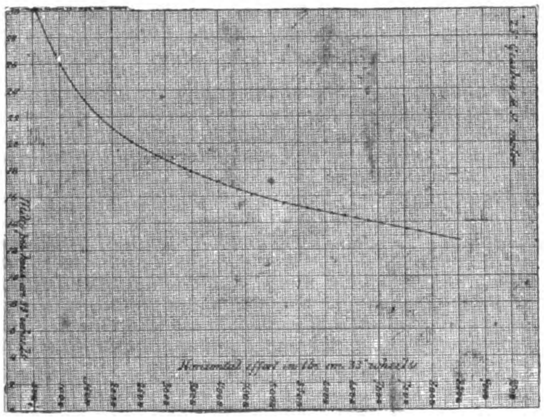

FIG. 3.

You can easily understand that this motor now makes it possible for us to develop large electric locomotives to be used in elevated railway service, and for pulling suburban trains in and out of large cities. From calculations and designs which we have made, we find that the size and weight of the motors required for 200 and 400 h. p. locomotives is not more than is necessary to produce the required adhesion to the rails needed for the required tractive pull to move these heavy trains. The motors are not large comparatively, and their economy will be very great. We believe that this branch of electric railroading will develop rapidly and that within a few years gearless electric railway motors will be used in places, for purposes and in numbers unthought of at the present time.

THE ELECTRIC INDUSTRIES OF NASHVILLE.

BY PROF. F. A. CHASE, FISK UNIVERSITY.

THIS is an inland city of about 60,000 people, and represents fairly well, probably, the progress of electric industries throughout the country. The earliest, of course, is the telegraph. The first line reached Nashville in 1847. The bulk of the business has been done by the Western Union, or its corporate progenitors. Its building having been burned about a month since, it is now doing business in temporary quarters. It has in use 11 quadruplex instruments, 2 duplexes and 25 single Morse sets. In the permanent building it will have a battery of about 5,000 cells. An estimate has been made on the cost of engine and generator, but it was decided that such a change could not be made with economy, until there was a demand for the equivalent of 10,000 cells. There is a district messenger system with wires running to the principal business offices. Dispatches are supplied to three dailies, and there is a business, including repeated messages, of about 200,000 dispatches a month. The Postal Telegraph-Cable Company does a local business in the city of 60,000 messages a month, besides about 20,000 relay messages.

The first telephone used in the city was made by J. W. Braid, from drawings given in the *Scientific American*. This was in September, 1877, and was attached to a line connecting three places in the city. The first commercial line was erected in December, 1879, between the furniture store of Messrs. Weakly & Warren and their factory in the suburbs. A company was organized about this time, an exchange office established, and the business rapidly extended. It now has 1,651 subscribers, who pay an average rental of $5 per month. Lines are extended to 14 sub-exchanges in the country about. For distances not exceeding 40 miles the charge is 25 cents, for longer distances up to the limit of 110 miles, the charge varies from 35 to 45 cents.

The vicissitudes that have marked the development of commercial electric lighting throughout the world have been typified by the changes that have characterized the business in Nashville. The first company was organized in 1881 with a capital of $50,000. This was in the days when it was supposed that there was only one firm in the country that could furnish a complete plant. There were reorganizations in 1885 and 1889. In 1890 the Thomson-Houston Company got the contract for lighting the city, and the original company bought it out, giving bonds to the amount of $200,000. The company is now about to be sold out to the Thomson-Houston, it is supposed, for non-payment.

It has 60 Thomson-Houston 50 arc dynamos, two old Brush dynamos—in use since 1881—one of 55 lights and the other of 28 lights, three Westinghouse alternators of 1,000 lights each, two Westinghouse of 150 lights each, one Thomson-Houston alternator of 1,000 lights, and one Thomson-Houston generator of 60 electric h. p. for motor work. The power is furnished by two Westinghouse 150 h. p. engines, two Ball of 60 h. p. and three Phœnix of 100 h. p. The boilers were made by the Phœnix and Erie City firms.

There are isolated plants in three hotels, three cotton mills, five flouring mills, one cotton-seed oil mill, two railroad shops, two parks and the water-works, all but three using the incandescent light alone.

The United Electric Street Railway was organized in February, 1890. The capital stock is $1,000,000. It issued bonds for the old street car franchises to the amount of about $1,500,000, for plant of about $1,000,000, which has since been increased to a total of $2,700,000. It has 52 miles of track, 63 motor cars (four more to be added), and 13 trail cars. The motor cars are from the following firms: Westinghouse, 4; Sprague, 20; and Thomson-Houston, 39. The current is supplied by seven Thomson-Houston and two Edison dynamos. Of the eight boilers six are from the Phœnix and two from the Taylor Manufacturing Co.

All of the eighteen lines converge at the public square, and vary from one to five miles in length. The fare is uniformly five cents. Transfer tickets are issued on all lines, so that passengers for the same fare may ride the whole extent of any two lines (except parallel lines going to the same district), averaging six or seven miles.

There is a smaller road running out to a suburb four miles distant. It has five cars and uses the Edison system. Though the line does not run in a thickly settled region, the investment is said to be paying fair profits.

There has thus far been but little development of the electric motor in small manufacturing establishments. There is also little electroplating. But the fact that the city electric light and the street car firms have shops where they do their own electric repairing shows the great increase of mechanics in this line of work.

There is one electric supply store having a stock varying from $5,000 to $8,000, kept by Mr. J. W. Braid, who also keeps a small force of hands at work in wiring buildings, putting in bells, annunciators and independent lighting plants.

A READER at one of the large universities writes us that THE ELECTRICAL ENGINEER is "growing in popularity with the students, which it justly deserves."

A NEW WIRT SWITCH.

THE ELECTRICAL CONSTRUCTION Co., Chicago, have just completed a very neat and successful piece of advertising work, which, while not original in design, is carried out on a scale beyond anything heretofore attempted. It consists of a sign built up of incandescent lamps, over 300 altogether being used. This is placed on the front of one of the large dry goods houses and has attracted thousands of spectators every night by its brilliant display.

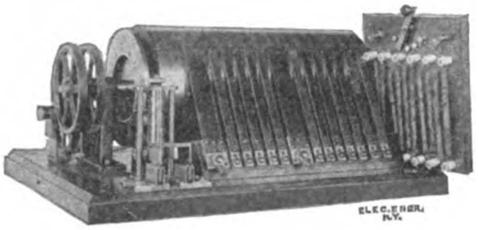

FIG. 1.—WIRT SWITCH FOR ADVERTISING SIGNS.

The accompanying illustrations, Figs. 1 and 2, are views of the automatic switch used to effect the combination of the different letters. A cylinder provided with copper contacts of varying extent is driven at a uniform rate by a small electric motor through a train of gearing. The separate copper springs bearing on this cylinder, one for each letter, throw them into circuit in succession, after which the operation of a cam at the end of the cylinder throws off the whole at one time. This arrangement prevents any sparking on the surface of the cylinder, as the contacts are made individually at this point, but broken collectively by the main switch. This switch is the design of Mr. Charles Wirt, of The Electrical Supply Co., Chicago.

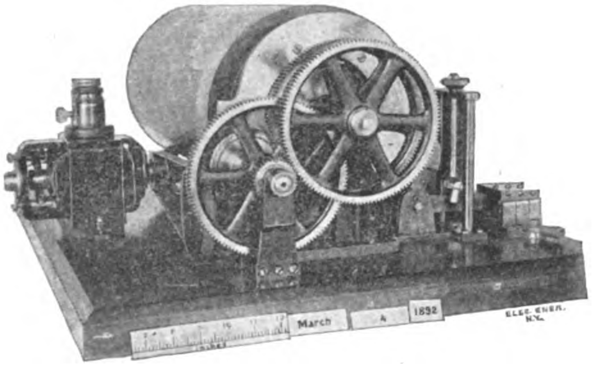

FIG. 2.—WIRT SWITCH FOR ADVERTISING SIGNS.

Letters to the Editor.

ENERGY BY THE ROOMFUL.

IN the article by Mr. Gordon, published in the *Nineteenth Century*, and reprinted on page 340 of THE ELECTRICAL ENGINEER, of March 30, referring to the modern conceptions of the nature of force, the author remarks:

> "Prof. Crookes has shown that the forces contained in this bombardment are immensely greater than any forces we have yet handled, many millions of horse power being contained in an ordinary room. Owing, however, to the forces being in every possible direction, they neutralize each other and no result of them is perceivable to our senses; but if ever we discover how to so direct their courses as to send the majority of them in the same direction, we shall have at our disposal forces as much exceeding any we are now acquainted with as the blow struck by a bullet exceeds the force required to pull the trigger of a gun."

As a curious illustration of the way in which different minds may sometimes be led to view a corresponding subject from the same point of view, permit me to quote from a pamphlet in my possession published now more than ten years ago by Chauncey Smith, one of the most eminent members of the Boston bar. Mr. Smith says:

> "The present scientific belief is that the atmosphere is an aggregation of infinitely small molecules, which really fill but a small part of the space the air seems to occupy; that through the unoccupied space these molecules are rushing at a high speed, hitting each other and the solid bodies around them and rebounding, and that what we call the pressure of the atmosphere, fifteen pounds to the inch, is really the bombardment of these molecules upon whatever arrests their course. The reason that all solid things are not swept away by this incessant pounding is, that the blows are struck in every direction, and so neutralize each other. But here is an ever-present and ever-active force, and if man should ever discover a way to make all the particles of a body of air move in one direction, he would have at every place on the surface of the earth an unlimited amount of power placed at his command."

FRANKLIN L. POPE.

Literature.

Die Elektrische Schweissung und Löthung. (Electric Welding and Soldering.) By Etienne de Fodor. A. Hartleben. *Vienna:* 1892. Paper, 5½ by 7½. 236 pages. Price $1.20.

ALTHOUGH much progress has been made in the domain of electric welding and soldering, the literature on the subject has been scattered through so many journals that the student desiring to make a systematic study of the progress of the art has up to the present been compelled to wade through many isolated papers and discussions. The volume before us is the first in which we are presented with a systematic treatment of various methods which have been proposed, or which have already come into practical operation.

A glance at the volume shows that electric welding and soldering has displaced not only hand processes in many instances, but that it has created more than one new industry. The already large list of inventors whose methods are described in this work shows that this field is one which has found active workers in many directions, and although it may be claimed by some that much that has appeared in electric metal working has proven impracticable, it cannot be denied that the actual work already accomplished is certain to be the forerunner of what will eventually turn out to be little less than a revolution in many metal-working processes. Naturally the work of Prof. Elihu Thomson occupies a prominent position in the volume before us, and the descriptions of his various machines and processes form several interesting chapters. We also find descriptions of methods employed by Benardos, Coffin and others in the applications of the arc for the welding of metals and various other processes due to Burton, Lieut. Wood and others. The author has collated also very full data on the results of electric welding relative to the mechanical strength of the finished product. The book will afford interesting reading, not only for the electrical and mechanical engineer, but for all interested in technical work. The illustrations throughout are very clear, and we note, with pleasure, that the author gives frequent references to original sources, and includes a very complete index.

Telephon, Mikrophon und Radiophon. By Theodore Schwartze. Third edition. A. Hartleben. *Vienna:* 1892. Paper, 5¼ by 7½. 253 pages. Price $1.20.

THIS work, constituting one of the first in the Electrotechnische Bibliothek series has been revised and now gives a well-connected history of the telephone and describes various forms of telephones, microphones and radiophones. The work lacks, somewhat, the details of more modern American practice, which, however, may be pardoned from the fact that this practice has been very largely withheld from publication. The chapter on the phonograph, with which the book ends, does not show the most recent form of that instrument. The author still confines his description to the old tinfoil cylinder; his remark, therefore, that the phonograph has not reached a state of practical importance is based on the assumption that the instrument has received no improvements on its first form, an assumption which it is needless to say is not borne out by facts.

L'Annee Electrique. By Ph. Delahaye. 7th year. Baudry & Co. *Paris:* 1892. 4¾ by 7½. Price, $1.00.

THESE annual volumes, containing the progress of each year preceding their issue, are too well known to require any special notice. We may merely remark that the author has carefully noted the principal events of the year in all departments, so that the reader is afforded, within a small compass, an epitome of the year's work.

Harmonized Melodies. Arranged by Charles D. Blake. *Boston,* F. Trifet, 408 Washington street. 256 pages, 12 x 9 inches. Price, boards, $1.; cloth, $0.60.

BY presenting to the musical world a collection of 400 songs, giving not only the words and solos, but all the instrumental accompaniments complete, the publisher of "Harmonized Melodies" has preserved for modern use scores of the most popular old and new songs of our century.

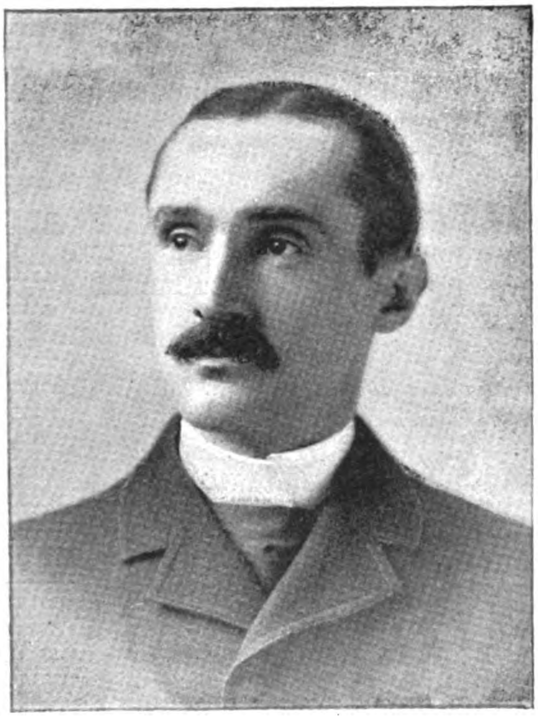
The arrangement of the music is a special feature of the volume, and is the work of Mr. Charles D. Blake, the eminent Boston composer, which fact alone speaks volumes, while the name of the publisher is another indication of the value of the book.

Personal.

S. M. HAMILL.

Mr. S. M. Hamill, recently elected secretary and general manager of the Brush Electric Company, is a conspicuous example among the large number of relatively young men who have achieved positions of prominence in the electrical industry.

Born in Lawrenceville, N. J., he prepared at the Lawrenceville School for Princeton College, where he was graduated in 1880 with the degree of B. A. He has since received the degree of A. M. After leaving college he taught for three years in the Lawrenceville School, during a portion of which time he studied law. Having a desire for active business pursuits, and determined to go to work, he secured, in 1884, a position as clerk on the freight platform of the Chicago, Burlington and Quincy Railway Company, in East St. Louis, and subsequently became private secretary to the agent, clerk in the paymaster's office, and in the first vice-president's office in Chicago. In 1886 he was in charge of the large grain elevators owned by the Chicago, Burlington and Quincy Railway Company, in Peoria, Ill., from which place he went to Cleveland to accept the position of assistant secretary of the Brush Electric Company. In 1889 he was elected secretary and moved to New York, where for three years he had charge of the general Eastern business of the company. During that period his business relations brought him general acquaintance in New York and the respect of all with whom he came in contact. At the last annual meeting of the Brush Company he was elected a director, secretary and general manager of the company.



S. M. Hamill.

Mr. Hamill is also president or secretary and director in a number of local electric light companies, and at present receiver of an electric company in Pittsburgh, Pa. While in Princeton he was one of the founders of the Ivy Club, and is a member of the Electric and University Clubs of New York and of the Electric and Union Clubs of Cleveland.

Mr. Hamill's successful career, although now covering only twelve years, well illustrates the mere utility of education—general training of the mind—to one of native capacity; to say nothing of its value in developing the graceful and genial qualities of mind and heart which have made friends of all his acquaintances.

Mr. George L. Colgate, E.E., has taken charge of the electric light and power plant at Roanoke, Va., which now has a capacity of 5,000 incandescents, and has begun to operate arcs. The plant now runs continuously except between 10 A. M. and 1 P. M., on Sundays.

Society and Club Notes.

MONTHLY DINNER OF THE BOSTON ELECTRIC CLUB.

The Boston Electric Club held its second dinner of the season at Young's Hotel, on Wednesday evening, the 6th instant, President Cram presiding. About fifty members and friends sat down to the dinner, which was a marked success in every way. Mr. William Stanley, Jr., was the guest of the evening, and afterwards read a most interesting paper, devoted to a profound discussion on the marvelous properties of ether as the medium for transmission of every form of energy. After the paper a number of questions were asked by various members of the club, and promptly answered by Mr. Stanley. A thoroughly enjoyable and profitable evening was spent, and it is to be hoped that these dinners will be held regularly in the future, and that members will assist by their attendance.

At the conclusion of the dinner, the president introduced Mr. Wm. Stanley, Jr., who spoke on the universal medium, the ether, especially in its relation to the propagation of electrical impulses and waves. While experimental evidence at first seemed contradictory the result of many experiments and observed phenomena led to the inevitable conclusion that the entire universe is filled with something which forms the highway over which all energy whether as heat, light, electricity, magnetic or chemical action is conveyed. This medium though extremely dense and of perfect elasticity was nevertheless so constituted that it permeated all matter, passing through solid bodies much in the same fashion as air passes through gauze.

To illustrate the method of propagation of impulses through the ether, Mr. Stanley pictured to his hearers a tube of some perfectly elastic material enclosing ether, reaching between Boston and New York, branching out at the latter place so as to act respectively upon a thermometer, a man's eye and a bottle containing hydrogen and chlorine. If now at the Boston end we began to deliver blows at an ever-increasing rate upon the cap closing the end of the ether tube, the first effect noticed at the New York end would be a rise in the thermometer, indicating an increse in temperature. As the rate of the blows was still further increased the man's eye would perceive light, beginning with red and passing through the various colors of the spectrum to violet; till finally at a still higher rate of vibration of the ether due to the blows chemical action would take place causing the hydrogen and chlorine to combine to form hydrochloric acid.

To form some idea as to the manner in which current is conveyed in a conductor, we might conceive, for instance, that an alternate current generator was a device which, when connected to the ether contained in the wire gives it a peculiar screw-like thrust in alternate opposite directions. These cause the ether in the wire to be driven or compressed in the direction of the length of the wire, and this compression may be thought to represent a flow of current.

Each impulse conveyed to the wire is radiated outward into space, so that if we could make an alternator that would twist the ether 400 or 500 billion times per second, we would radiate light from the conductor, or in other words the conductor would be luminous. Mr. Stanley thought it possible and highly probable that in the future we shall discern the means of producing a sufficient number of alternations per second to cause special apparatus through which they are made to pass to glow with waves of light without accompanying heat. The investigations of Mr. Tesla and the researches of many investigators make this result probable, and when that time comes, light will be the cheapest force at command.

A few years ago, said Mr. Stanley, we inadvertently conceived that we *made or generated* electricity; to-day we consider that the universe is an infinite sea of energy in which all matter is but incidental, all bodies but temporary or momentary constructions through which or by which this unseen energy may become apparent to our senses.

GRANT MONUMENT ASSOCIATION.

The following gentlemen have been named to act as members of committees representing the electrical industries, co-operating with the Grant Monument Association, in common with every other interest in the city. The amount required to finish Grant's monument and tomb on Riverside drive is $350,000, and the cornerstone is to be laid by President Harrison on April 27, with imposing ceremonies. Foundations of granite 10 feet high have already been laid:

Telegraph—Thomas T. Eckert, chairman; A. B. Chandler, James Brown. *Fire Alarm and Police Telegraph*—Joseph Stover, chairman; J. S. Morse, P. N. Ramsey. *Electrical Supplies*—E. S. Greeley, chairman; H. B. Thayer, J. H. Bunnell. *Electric Light Companies*—Henry Villard, chairman; C. J. Canda, A. D. Dorman, George W. Hebard. *Telephone Interests*—David B. Parker, chairman; Charles Dutton, W. D. Sargent. *Burglar Alarms*—

E. Holmes, chairman; Frederick Pearce. *Electrical Press*—C. W. Price, chairman; W. J. Johnston, Joseph Wetzler. *Electricians*—F. L. Pope, chairman; H. W. Leonard, George d'Infreville. *Electrical Protection*—E. Holmes, chairman.

Legal Notes.

A STORAGE BATTERY DECISION IN FAVOR OF THE ACCUMULATOR CO.

ANOTHER aspect to the interminable storage battery litigation is given by Judge Coxe, in the United States Circuit Court, who filed a decision on April 9 in the suit brought by the Accumulator Company, the owners of the Swan patent, against the New York & Harlem Railroad Company, to restrain them from using the Swan perforated plates in the storage batteries by which the electric cars which ran over the city route of the 4th avenue road were propelled. The decision was in favor of the Accumulator Company.

The suit was defended by the Consolidated Electric Storage Company, which controls the Brush patents that relate to the "active material," and that have been sustained so broadly.

Judge Coxe said, in rendering his decision, that he was sustained by many previous similar decisions in suits of this nature. In every case where suit has been brought by the owners of the Swan patent they have proved conclusively their exclusive right to the grid or perforated electrode.

Reports of Companies.

ANNUAL REPORT OF THE THOMSON-HOUSTON ELECTRIC CO.

THE annual meeting of the stockholders of the Thomson-Houston Electric Company was held in Middletown, Conn., on Monday, the 11th instant, when the accompanying statement was presented and the following directors elected for the ensuing year: H. A. Pevear, C.A. Coffin, J. N. Smith, B. F. Spinney, Chas. H. Newhall, S. A. Barton, Eugene Griffin, S. E. Peabody, T. J. Coolidge, Jr.

The report presented is given herewith in full. It was prefaced by a little introductory statement by Mr. C. A. Coffin, first vice-president, and accompanied by a number of tables bearing on the growth of the business. Mr. Coffin called attention to the depression general in 1891, and said that during the first half of the year, the gross and net business of the company fell off 30 per cent. This was, however, almost wholly made up in the second half, and at the date of the report, February 1, 1892, the orders on hand were more than double those at the same period in 1891. The business from the Boston office was $10,304,580 or about $100,000 more than in 1890. Mr. Coffin also referred to the decision sustaining the Brush double-carbon lamp patent, and pointed to the great growth in the number of local lighting companies and street railway companies. He also referred to the good fortune of the company in marketing local company securities at good prices through the United Electric Securities Co. Mention was also made by Mr. Coffin of the good work of the new purchasing department, the new meter department handling the Thomson recording wattmeter, and the promising development of electric locomotives for heavy work. The statement of profits and loss surplus account showed $1,524,414.25 addded to surplus from profits in 1892, making a total surplus of $7,546,947.96. The addition for 1892 is after paying 7 per cent. dividends on preferred and quarterly dividends at the rate of 16 per cent. on common.

BOSTON, March 29, 1892.

The condition of the Thomson-Houston Electric Company, as disclosed by the Balance Sheet at the close of the last fiscal year, is respectfully submitted herewith.

The Liabilities, as shown in the statement, do not include $500,000 Thomson-Houston Collateral Trust Bonds, which were issued in 1889 as an accommodation to the Manhattan Electric Company of New York. The Manhattan Company, besides assuming the entire burden of paying the principal and interest of these bonds, supplied the Thomson-Houston Company, without cost to it, with ample collateral security for the same.

The Thomson-Houston Electric Company has received from its stockholders from time to time, $10,500,000 in actual cash from subscriptions to its common and preferred stock. The last issue of common stock, amounting to $1,500,000 at par, was sold in September, 1890, at 100% premium, yielding to the treasury $3,000,000 in cash.

Thus $1,500,000 of the surplus of the company on Feb. 1, 1891 ($6,022,533.71), is represented by premium received from the sale of common stock; the balance by accrued surplus earnings of the company.

The surplus net earnings for the fiscal year just closed, after deducting $1,236,366 paid during the year as dividends on common and preferred stock, is $1,524,414.25, making the total surplus, Feb. 1, 1892, $7,546,947.96.

Prior to March 1, 1892, there had been paid to the stockholders in cash dividends a total of $1,731,131.88. In addition to this, there had been distributed among the stockholders as a special dividend $1,000,000 of common stock at par, which was taken from the surplus account of the company April 15, 1889, and securities of the par value of $2,416,468.27 were placed in the hands of trustees for the benefit of the stockholders of the company, Oct. 5, 1889.

There has also been sold to trustees for the further benefit of stockholders of the parent company, stocks and bonds of local companies, classed as Thomson-Houston securities, series "A," "B," and "C," from which the shareholders have realized as profit, in excess of cost to them, an amount which, added to the present market value of the shares, would aggregate $775,000.

THOMSON-HOUSTON ELECTRIC COMPANY.

Balance Sheet, January 30, 1892.

ASSETS.		
Accounts Receivable, Mdse	$6,601,298.03	
Less Deductions, 10% (*a*),	660,129.30	$5,941,168.73
Notes Receivable	1,636,800.85	
Less Deductions, 7½% (*b*)	122,760.03	1,514,040.82
Cash		1,727,276.16
Real Estate, about 70% of cost		430,241.24
Machinery and Tools, about 60% of cost		491,044.53
Office Furniture and Fixtures (*c*) Cost $27,334.23 (charged off)		
Patterns and Models		135,000.00
Patents { Expense for the year charged off } (*d*)		338,854.29
Local Co.s' Stocks, 35% of par (*e*)		473,586.60
Local Co.s' Bonds, 70% of par (*f*)		1,858,570.00
Manufacturing Co.s' Stock, at cost (*g*)		8,729,195.50
Construction Co.s' Stock, at cost (*g*)		1,210,750.00
United Securities Co.s' Stock, at cost		525,420.00
Consignments		32,116.79
Merchandise Inventory, Factory (*h*)		1,731,481.55
Merchandise Inventory, Ry. Supply Dept		72,593.23
Merchandise Inventory, Ltg. Supply Dept		52,613.63
		$20,263,447.57
LIABILITIES.		
Capital Stock—Common		$6,000,000.00
Capital Stock—Preferred		4,000,000.00
Accounts Payable—Merchandise		498,808 24
Notes Payable—Collateral		1,429,486.14
Notes Payable—Unsecured		587,005.23
Mortgage		1,200 00
Guarantee Account (from accrued surplus)		200,000.00
Surplus February 1, 1891		6,022,533 71
Profits for the year	2,760,780.25	
Less dividend paid during the year	1,236,366.00	1,524,414.25
		$20,263,447.57

STATEMENT OF SURPLUS ACCOUNT.

Surplus February 1, 1891	$6,022,533.71	
Income for year ending January 30, 1892, after deducting dividends paid during the year	1,524,414.25	
Surplus January 30, 1892		$7,546,947.96

BENJ. F. PEACH, JR.,
First Assistant Treasurer.

In explanation of the deductions made from the assets of the Company, it may be stated that following the conservative policy that has always prevailed, allowances have been made with an idea of placing upon each and every asset a value which will be safe in any contingency.

(*a*) From Accounts Receivable, the same deduction has been made as in former years. This has in previous years always been found ample.

(*b*) The deduction of 7½ per cent. from notes receivable is 2½ per cent. in excess of the rate deducted in former years, and is regarded as more than a sufficient guarantee for contingencies.

(*c*) Following the precedent of last year, the expense incurred for office furniture and fixtures during the year has been charged to expense account.

(*d*) While a large sum has been expended during the past year in the acquisition of patents, this has all been charged to current expense instead of adding to the patent account.

(*e*) In local companies' stocks a deduction of 65 per cent. is made, which is 5 per cent. in excess of deductions in former years. More than $200,000 of stocks and bonds of railway and lighting companies at par value are carried in a separate account as of doubtful, though of considerable prospective value, and do not appear in the inventory at all.

(*f*) These bonds are nearly all payable in gold, and are amply secured by sinking funds and other protective provisions, made under the supervision of competent attorneys of our own selection. A large profit should be realized from the sale of these bonds.

(*g*) The Manufacturing and Construction Companies' stocks are taken at their cost value. The companies represented by these stocks are making very satisfactory earnings and working in harmony with the Thomson-Houston Co., thereby contributing largely to the success of this company.

(*h*) The inventory of merchandise and material at the factory has been taken in the usual way, *at less than actual cost.*

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 29, 1892.

Accumulators :--

Storage Battery Plate and Process of Making the Same, W. W. Donaldson and R. Macrae, 471,538. Filed Aug. 18, 1891.

Claim 1 follows:

A storage battery plate having perforations through both the active and inactive material and a space between the adjacent inner surfaces of the active material.

Secondary Battery, C. F. Winkler, 471,590. Filed Nov. 8, 1890.

The plate consists of a series of lead troughs placed one above the other and containing the active material.

Secondary Battery Electrode, C. F. Winkler, 471,591. Filed June 26, 1891.

Similar to 471,590.

Secondary Battery, C. F. Winkler, 471,592. Filed Sept. 29, 1891.

Employs a grid of insulating material capable of being made very light in weight.

Alarms and Signals :—

System for Transmitting Signals, H. A. Chase, 471,584. Filed Nov. 27, 1891.

A system in which one wheel may transmit its signal without additions, subtractions, repetitions or change of character over two different paths for two different purposes.

Automatic Guest Call, W. H. Perry, 471,686. Filed May 9, 1890.

Automatic Electric Fire Alarm, L. G. Woolley, 471.929. Filed Dec. 14, 1891.

Electrical Annunciator, N. M. Watson, 471,986. Filed Jan. 2, 1891.

An annunciator which does not require restoring after indicating the call.

Electrical Annunciator, N. M. Watson, 471,987. Filed Aug. 17, 1891.

Provides means for showing from which of two push buttons a call is being made.

Conductors, Conduits and Insulators :—

Insulated Electric Conductor, J. B. Williams, 471,587. Filed July 10, 1890.

Employs an exterior insulating layer and an intermediate corrugated covering, the poles of which form with the exterior layer the walls of continuous air passages.

Insulated Electric Conductor, J. B. Williams, 471,588. Filed Apr. 9, 1891.

Similar to No. 471,587.

Joint for Electric Wires, R. H. Smith, 471,625. Filed Aug. 24, 1891.

A screw coupling for trolley wires.

Dynamos and Motors:—

Dynamo-Electric Generator or Motor, C. W. & L. B. Atkinson, 471,691. Filed Aug. 18, 1891.

Provides means for enclosing brushes and commutators so that the machine may be worked in the presence of inflammable or explosive gases.

Dynamo-Electric Machine or Motor, W. T. Goolden & L. B. Atkinson, 471,-693. Filed Aug. 18, 1891.

Similar in its object to 471,691.

Commutator Brush, R. Hirsh, 471,792. Filed Oct. 29, 1891.

The brush consists of a number of strips each independently coated with a film of electrically deposited metal, the whole being then united by means of a second film.

Brush-Holder for Electric Motors or Dynamo-Electric Machines, C. A. Hussey, 471,819. Filed May 6, 1889.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, W. Burnley, 471,945. Filed June 18, 1891.

A dry cell battery in which the negative element is enclosed within a porus cup in which a depolarizing compound is packed, the exciting composition. forming a layer between the open lower end of the porous cup and the bottom of the outer zinc jar.

Lamps and Appurtenances :—

Manufacture of Incandescent Electric Lamps, F. S. Smith, 471,576. Filed Dec. 22, 1890.

Employs leading-in conductors of iron upon which the glass of the enclosing chamber is fused, and a cement surrounding the iron wires at the point of entrance.

Support for Electric Lamps, C. J. Klein, 471,645. Filed Dec. 1, 1890.

Provides means for attaching lamps of different makes to the same support.

Mast-Arm Switch for Electric Lamps, T. Dillon, 471,730. Filed Nov. 4, 1891.

Bracket for Incandescent Electric Lamps, J. G. Goehst, 471,732. Filed Mar. 9, 1891.

Support for Electric Lights, J. J. Walsh, 471,837. Filed Sept. 15, 1891.

Electric Light Crane, J. Gallagher, 471,968. Filed July 13, 1891.

Miscellaneous :—

Governor for Marine Engines, E. F. Wallgren, 471,725. Filed Dec. 8, 1891.

Employs a throttle valve electrically actuated through the medium of a float.

Pole for Supporting Electric Wires, J. H. Huntress, 471,759. Filed Oct. 24, 1891.

Electric Telpherage Apparatus, M. W. Hassan, 471,790. Filed Dec. 29, 1890.

An electrical apparatus for the rapid transit of small packages.

Determining the Temper of Iron or Steel, C. A. Casperson, 471,809. Filed Sept. 19, 1891.

Consists of conducting electric currents through the pieces to be tested and simultaneously through another piece whose temper is known and conducting the heat developed by the currents to the thermometers.

Electro-Therapeutic Electrode, H. Bonis, 471.850. Filed Aug. 10, 1891.

Electric Lock, J. G. Thompson, 471,913. Filed Aug. 12, 1891.

Electrically Controlled Trap Door, F. C. Callahan, 471,947. Filed Dec. 14, 1891.

Endoscopic Instrument, J. W. Daily, 471,990. Filed Oct. 14, 1891.

Valve Controller, N. E. Nash and G. A. Eddy, 471,999. Filed Nov. 20, 1890.

An automatic electric controller for steam engine valves.

Method of and Apparatus for Producing Musical Tones by Electro-Magnetism, E. C. Ohmart, 472,019. Filed April 28, 1890.

Railways and Appliances :—

Electric Railway, W. C. Goss, 471,543. Filed Apr. 3, 1891.

Consists in improvements relating to the housing which incloses the supply conductor and its combination with the rail beds and supply conductor.

Device for Transmitting Motion, G. S. Strong, 471,655. Filed May 29, 1891.

A fluid-valve for electric street car motors.

Device for Transmitting Motion, G. S. Strong, 471,656. Filed May 29, 1891.

Similar to 471,655.

Switches and Cut-Outs :—

Electric Switch, H. Hubbell, 471,612. Filed Oct. 5, 1891.

An inexpensive, quick-acting switch.

Electric Switch, C. G. Perkins, 471,760. Filed July 24, 1888.

An electric switch in which power is stored by the turning of a shaft and afterward released by the withdrawal of the detent.

Reciprocating Snap-Switch, J. S. Gibbs, 471,993. Filed July 3, 1891.

Automatic Electric Cut-Out, E. A. Manship, 471,997. Filed June 30, 1891.

Employs a pawl adapted to hold the switch in a closed position, a solenoid, a core therefor and adjustable extensions.

Telephones and Apparatus:—

Telephone Receiver, J. A. Christy and E. J. Baldwin, 471,535. Filed Mar. 16, 1891.

Employs a system of perforated magnetic tubes in the chamber of the receiver connected to the actuating electromagnet and extending up to the diaphragm.

Attachment for Telephones, J. E. Hills, 471,549. Filed Apr. 27, 1891.

Telephone, J. H. Howard, 471,745. Filed Sept. 21, 1891.

A simple arrangement of the magneto box by means of which the necessity of making connection through the hinges at the front of the box is obviated.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS, ISSUED APRIL 5, 1892.

Alarms and Signals :—

Electric Indicator for Railroad Blocks, R. W. Jaggard, 472,359. Filed April 6, 1891.

Annunciator, W. C. Dillman, 472,439. Filed Dec 22, 1891.

An annunciator for use in connection with a speaking tube.

Annunciator, W. C. Dillman, 472,440. Filed Dec. 22, 1891.

Similar to No. 472,439.

Electrical Indicator, J. W. Henderson, 472,500. Filed Nov. 18, 1885.

Provides means whereby various portions of a distant moving object may be automatically indicated.

Conductors, Conduits and Insulators :—

Compound for Insulating Electric Wires, L. Hill, 472,352. Filed July, 11, 1891.

Consists of pittizite pitch, candle tar, coal tar, asphalt pitch, and rosin.

Distribution :—

System of Electrical Distribution, W. Marshall, 472,193. Filed Feb. 28, 1891.

System consists in carrying a direct current for a long distance over a small wire, the distribution being effected by means of condensers and the circuits being controlled and operated by a quick-acting switch or commutator.

Production and Distribution of Electricity, W. Marshall, 472,379. Filed Nov. 23, 1889.

Consists in alternately charging a condenser and throwing into the line beyond the condenser the currents of the condenser and the electric source; these acts being performed with such rapidity that the effects in the line appear continuous.

Galvanic and Thermo-Electric Batteries :—

Thermo-Electric Element, E. N. Dickerson, 472,037. Filed Feb. 27, 1890.

Consists of a series of parallel plates of different metals held firmly in contact with each other and adapted to be heated at one end.

Thermo-Electric Battery, R. J. Gülcher, 472,261. Filed June 18, 1891.

An improved form of the Gülcher thermopile.

Lamps and Appurtenances :—

Rheostat, J. R. Masury, 472,062. Filed June 20, 1891.

A rheostat for use in connection with incandescent lamp circuits.

Electric Arc Lamp, J. A. Mosher, 472,064. Filed June 20, 1891.

Has for its objects to provide an all-night lamp using a single carbon only and at the same time to decrease the length of the lamp.

Electric Arc Lamp, S. W. Rushmore, 472.274. Filed July 27, 1891.

An arc lamp for incandescent circuits in which the feeding of the carbon depends partly upon the operation of a coil in series with the arc.

System of Arc Lighting, H. A. Foster, 472,346. Filed Jan. 29, 1891.

Has for its object the protection of the exposed conductors and complete isolation of the operating parts of the system for the purpose of safety.

Adjustable Armature for Electromagnets, E. Hofmann, 472,480. Filed Sept. 22, 1891.

An armature adjustable with relation to its magnet without destroying the proper relation between the two. Adapted to the operation of arc lamps.

Automatic Electric Lamp Lighter and Extinguisher, J. H. Caughy, 472,494. Filed Nov. 17, 1891.

A time switch for electric lights.

Measurement :—

Galvanometer, S. Bergmann and G. A. Scott, 472,026. Filed Feb. 25, 1891.

Claim 1 follows:

In an electric meter the combination of a magnet, a metal strip longitudinally curved and gradually widened from one end to the other and supported adjacent to the pole of said magnet, and a weight or its equivalent for moving the strip in the reverse direction to that in which it would be moved by the magnet.

Electrical Meter, J. F. Kelly, 472,265. Filed Aug. 18, 1891.

A coulomb meter, consisting of a motor having a constant field, a shunt around the terminals of the motor, a load consisting of a fan or other device and means for indicating the revolutions of the shaft.

Miscellaneous :—

Fare Register, C. B. Cushman and H. G. Canfield, 472,085. Filed Oct. 2, 1891.

Carbon Holder, H. Howard, 472,055. Filed Oct. 21, 1891.

Carbon holder for electric welding machines.

Lightning Arrester, E. G. Miller, 472,135. Filed Aug. 27, 1890.

A helix having a mercury switch at the bottom and a movable armature for displacing the mercury.

Process of Decorating Glass, J. H. Scharling, 472,230. Filed July 1, 1891.

A system of decorating glassware by electroplating directly upon the glass, which is first washed with a solution of metallic salts.

Electric Recording Device for Compasses, C. L. Jaeger, 472,134. Filed April 14, 1891.

Brush Holder, J. R. Coffman, 472,435. Filed Sept. 30, 1891.

A brush movably fixed in a slideway to be pressed against the commutator and means of adjustment for maintaining uniform pressure.

Electric Mining Pick and Drill, J. Fish, 472,444. Filed April 29, 1891.
Musical Instrument, C. E. Guerre and G. H. Martin, 472,453. Filed Jan. 21, 1891.

Musical instrument consisting of a sonorous body vibrated by means of an electrical device.

Electromagnetic Valve Controller, O. E. Lundstedt, 472,461. Filed Aug. 6, 1890.

Railways and Appliances:—

Hanger for Electric Wires, H. H. Luscomb, 472,220. Filed July 20, 1891.

A trolley wire hanger having a head, a stem at one end of which the head is pivoted, and an arm serving as a stop for the head and also to transmit a part of the strain on the head when in use to adjacent parts of the stem.

Electric Wheel-Locking Device, G. W. Blanchard, 472,329. Filed Aug. 10, 1891.

Has for its object to lock an electric car thus preventing it from slipping back when ascending steep grades on the failure of the motor actuating current.

Inclosed Supply System for Electric Railways, J. C. Fyfe, 472,447. Filed Dec. 26, 1890.

Has for its principal object to provide means for supplying current to the motors of moving cars without exposing the conductors or contacts.

Switches and Cut-Outs:—

Switch and Switch-Box, S. Bergmann, 472,087. Filed March 18, 1891.

A switch intended for use in connection with a conduit.

Safety Cut-Out, M. Thum, 472,084. Filed June 5, 1891.

Consists of a safety device comprising a branch circuit connected with the guarded circuit and an electro-mechanical device in the former circuit adapted to change the guarded circuit upon a change of current in the latter.

Switch-Box for Electric Motors, P. Wright, 472,283. Filed Jan. 31, 1891.

An electric motor whose field magnets are in circuit with a source of energy and its armature on a derived circuit, in combination with a pole-changing switch and a second normally open independent circuit connected to the armature, whereby the first circuit may be broken and the second closed or vice versa.

Telegraphs:—

Unison Apparatus for Printing Telegraphs, H. Van Hoevenbergh, 472,237. Filed July 20, 1891.

Has for its object to provide means whereby the transmitting operator may be informed whenever the type wheel of the receiving machine is out of unison with the shaft of the transmitting instrument.

Telephones and Apparatus:—

Toll-Collecting Apparatus for Telephones, J. J. Kato and T. H. Rhodes, 472,169. Filed March 28, 1890.
Telephone Transmitter, E. G. Acheson, 472,243. Filed June 29, 1887.

A simple, cheap and effective transmitter, little liable to get out of order, self-adjusting and sensitive to very slight sounds.

A SEARCH LIGHT ON MT. WASHINGTON.[1]

BY LEWIS H. ROGERS.

Some time since I conceived the idea of establishing a search light on the summit of Mt. Washington, and after two months of active work on this matter alone, I have arrived at the conclusion that the idea is of vast interest and inestimable value, not to New Hampshire alone, but to the world.

In the manufacture of search lights the parabolic reflector has been abandoned by the Thomson-Houston Electric Company except for the smallest lights used on yachts. It was found that the parabolic reflector caused the beam of light to diverge so that the intensity was lessened and there was a haze between the beam of light proper and the surrounding darkness. This bothered ocean pilots to such an extent as to lead to the invention of the "silvered lens," made of the finest glass and ground by the most skilled workmen. The arc lamp proper (a pair of 2-in. hollow carbons) is placed at the focal point, 14 inches in front of the concave side of the glass. In front of this large arc lamp is placed a small reflector, which throws the light back 14 inches on to the concave surface of the glass lens, which is silvered on its convex side, making it a powerful mirror. From the concave surface the light is refracted through the glass on to this mirror which sends the ray of light out through the glass, past the arc lamp with its small reflector and out through the glass door which encases the front end of the whole arrangement. The rays of light therefore come out of the projector in a single straight and very powerful beam, which stands out in the darkness of the night as distinct as though it were something on which one could walk, reaching perhaps a hundred miles, and all along the way it can be seen touching a hilltop here and there and illuminating whatever may be in its path. As we begin to realize that in all probability this beam of light can be seen from a half dozen States, the Dominion of Canada and from far out at sea, we get some conception of the intertest which will be centered in this single spot. Those who see it from afar will want to see it closer. Those who read of it in distant States and who start East for a pleasure trip will surely see the great search light on Mt. Washington before they return.

And now, gentlemen, in answer to the question, What can New Hampshire do to attract summer tourists? let me reply briefly: Place a powerful search light on the summit of Mt. Washington and by its side a powerful telescope.

This light, in all probability, will be seen from the State House in Boston, and if so, a similar one can be placed in Boston and telegraphic communication established between the two points—so with Portland—so with Montreal. There is no telling how far the light can be seen as there never was such a light placed at such a height. This will be the highest and the strongest beam of light in the world. Let New Hampshire take her stand on this matter and she will be well repaid.

A PERMANENT STANDARD MAGNETIC FIELD.

A PAPER on a "Permanent Magnetic Field" was, reports our London correspondent, read at a recent meeting of the London Physical Society by Mr. W. Hibbert. The author said he had observed the approximate constancy of an aged bar-magnet, and he obtained still greater constancy by attaching pole-pieces to a bar-magnet of such a shape as to give a nearly closed circuit of small magnetic resistance. The pattern described consisted of a steel rod 1 inch in diam. and about 2½ inches long, with a cast-iron disc 4 inches in diameter and ⅝ inch thick fixed at one end; the other end was fitted in a hemispherical iron ring shell which surrounds the bar and comes flush with the upper surface of the disc. An annular air space less than $\frac{1}{16}$ inch wide is left between the cylindrical surface of the disc and the inside of the shell, and when the bar is magnetized a strong magnetic field exists in this space. To use this field for producing electromagnetic impulses, a coil of wire is wound in a shallow groove on a brass tube which can slide axially through the annular space, thus cutting all the lines. The tube is allowed to fall by its own weight, a neat trigger arrangement being provided for effecting its release. The instrument exhibited had 90 turns of wire in the coil, and the total magnetic flux across the air space was about 30,000 C. G. S. lines. A large electromagnetic impulse is therefore obtainable even through resistances as great as 10,000 ohms. Tests of three instruments show that there has been practically no magnetic decay in seven months. The author, therefore, considers them satisfactory, and is prepared to supply them as magnetic standards. To facilitate calculation the number of lines will be adjusted to a convenient number, say, 20,000 or 25,000. Several uses to which the instruments are well suited are mentioned in the paper, and a simple method of determining permeability by the magnetometer method is described.

ELECTRICAL DEVELOPMENT AT TROY AND PORT HENRY, N. Y.

THE work of applying electric power on the Troy City Railway is to be pushed at once, and in the course of the next two months the road will be in full operation to Albia. The erection of the power station will be hastened, and, if possible, completed before May 1. The contracts for machinery have been signed, and that branch of the work is already under way. The dynamos and engines will be ready to place in position as soon as the building is in condition to receive them. The Edison system will be used on this route, which has heavy grades. The Fifteenth street branch will be pushed to completion as soon as the legal proceedings now in progress are finished and the street formally opened and graded.

The Troy and Lansingburgh Railroad are busy with plans for the depot loop. The Mill street extension and Fourth street branch are only waiting for the street improvements to be made when the track force will at once begin with ties and rails.

The electric light station has placed a new 100 h. p. boiler, and the work on the additional plant will begin. Contracts have been let for building the new additions on the lot south of the present station, and as soon as the weather permits great progress in all the electrical lines will be made.

The village of Port Henry will have a complete electric street lighting system within the next three months. The National Electric Manufacturing Company of New York, of which Edward F. Murphy, of Troy, is president and Rensselaer County Treasurer Morey, treasurer, is engaged in organizing a local company to join with it in constructing and operating the plant. It is proposed to issue $25,000 in stock and $25,000 in bonds and expend the entire amount on the plant, which will be one of the best of its size in the entire country. The central station will be a brick building, and will contain a boiler of 125 h. p., an engine of 105 h. p. and dynamos of sufficient capacity to supply all demand. There are about eight miles of streets, and this will necessitate about thirty-two miles of street wiring, which will be upon poles of the most approved style. Over 1,700 lights have been engaged for stores and dwellings. This is outside of the number that will be necessary for the streets. It is proposed to buy in the Port Henry Gas Company, and thus give to the new company the benefit of the fullest possible demand from the start. The incandescent system will be used for streets and inside lights. The lamps will vary from 16 to 32 c. p., and the expense of the lights for house use, where meters are to be used, is equivalent to gas at $2 per thousand feet.

HOPE FOR THE WESTERN UNION.

THE Paris (Ky.) *Record* holds out to the Western Union Telegraph Company the following crumb of comfort:

"Frank P. Webb went to Lexington yesterday to take the position of bookkeeper for the Western Union Telegraph Company. This makes three Paris boys in that office, and were all taught by A. C. Adair, who says he can furnish the company a general manager if necessary."

---

[1] Abstract of a paper read before the New Hampshire State Board of Trade, Concord, March 1, 1892.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising is to business what exercise is to health.

THE GREENFIELD SWITCHES AND CUT-OUTS.

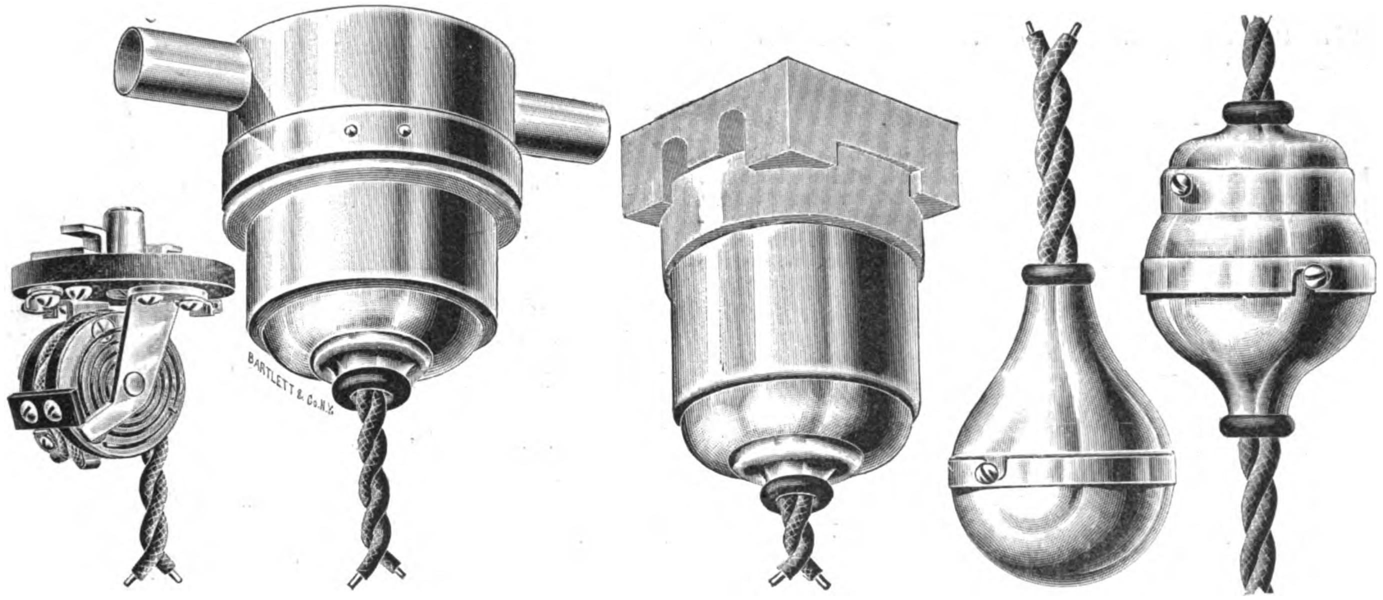
THE INTERIOR CONDUIT AND INSULATION COMPANY of this city have recently introduced a new combined pull switch and ceiling pendant cut-out, and also a new pendant pull switch, invented by Mr. E. T. Greenfield, the electrician of the company. These are made in a variety of forms, and are clearly shown in the accompanying illustrations.

Fig. 1 illustrates the interior mechanism which is employed in the different styles of switches and is concealed within the shells. This switch overcomes the difficulties experienced in turning on and off any style of key socket suspended from flexible pendants. Grasping either the cord or the lamp with the hand, the light may be turned on or off by a slight pull.

Fig. 2 shows the switch made to fit the standard conduit branch junction boxes and cut-outs manufactured also by the Interior Conduit and Insulation Company, and Fig. 3 represents the switch as adapted to the base of their "V. V." ceiling cut-out. The same mechanical principle employed in the combined pull switch and ceiling pendant cut-outs, is used to great advantage in the pendant pull switches.

Fig. 4 is a pendant pull switch designed for attachment to flexible cords for controlling incandescent lamps with the same freedom and safety as is experienced in handling an ordinary push button on an annunciator circuit. The switch may be used as a pendant from the centre of electroliers, thus dispensing with key sockets, and affording ready means for easily controlling the current. In general, it serves to bring within control lamps that are otherwise out of reach, permitting them to be turned on and off from any point that may be reached by a flexible cord.

Fig. 5 illustrates another application of the same mechanical principle embodied in the foregoing designs, and may be used with advantage in flexible cord pendants where it is not convenient to substitute the combined ceiling pull switch and cut-out for the ceiling block already in use. This switch may be inserted in any flexible cord pendant by simply cutting the cord and attaching the terminals to the binding screws provided for that purpose. As in the other forms of the same switch, the light may be turned on or off by a slight pull of the cord only. These switches are easily and quickly wired and are thoroughly reliable in every respect. In view of the fact that all the productions of the Interior Conduit and Insulation Company are noted for excellence of workmanship and finish, it is hardly necessary to state that the articles described above are compact in form and present a neat and attractive appearance. Once more this company have added a valuable article to their already long list of noteworthy specialties.



BARTLETT & Co. N.Y.

FIGS. 1, 2, 3, 4 AND 5.—GREENFIELD SWITCHES AND CUT-OUTS.

THE E. S. GREELEY & CO. FROM 1866 TO 1892.

NOTHING affords a more striking exhibit of the progress of electrical engineering during the past quarter of a century, than a comparison of the trade catalogues issued by prominent supply dealers then and now. In 1866 the firm of L. G. Tillotson & Co. then well-known manufacturers of railway supplies, decided to add a department of electrical goods to their business. The catalogue and price list issued at that time, now lies before us. It is a modest little pamphlet, 4 inches by 6, containing 20 pages, of which the last three are more than sufficient to accommodate the electrical department. As a contrast to this, the new catalogue of 1892, just sent out by the E. S. Greeley & Co., successors of the Tillotson house, is a thick book of no less than 450 pages, 5½ by 8½ inches, of which the index alone, closely printed in small type, occupies more than five times the space of the old catalogue. Only about thirty different articles are to be found on the original list, mostly telegraphic supplies, as in those days electricity was considered available for little else. The latest list embraces some thousands of different articles of every conceivable description, and more are being added every week, so that it is scarcely too much to say that a catalogue is out of date now-a-days almost before it can be got into print.

No less remarkable is the reduction in the prices of goods, which has been made possible by manufacture on a large scale, with improved and special machinery, and with studied reference to simplicity and effectiveness of design. In 1866 the price of the best Morse key was $7; a better one is now listed at $2. Relays were $22, not as good as now sold for $5. The sounder that cost $12 then, can be had for $3.50 now, and the reduction in other articles throughout the list is as great or greater than in the case of the apparatus mentioned.

At the time Tillotson & Co. embarked in this line of manufacture, there was only one other establishment of the kind in New York, and this one went out of business many years since. The old firm, and its successor, The E. S. Greeley & Co., have always maintained a leading position in the trade, and though they have made several removals, have always remained within a few doors of their original location at 26 Dey street. We venture to say that they will be found doing business at the old stand or in its immediate vicinity, 25 years hence, but how large a volume their catalogue will have expanded to by that time, is beyond the power of our imagination to undertake to prognosticate.

PEPPER & REGISTER.

THE above firm, of the Provident Building, Philadelphia, have secured the order to build and equip the Delaware Bay and Cape May Electric Railway, a six-and-one-half-mile road, with ten car equipments; generator to be 150 h. p., and cars to be equipped with 30 h. p. single-reduction motors, both of the Westinghouse Electric Company's manufacture. The Ball engine is to be used, Coatesville boiler and stack, Schieren's belts, Morris-Tasker Company's brackets for pole construction and Washburn & Moen's trolley wire. The road is to be in operation, complete, by the first day of June.

They have also secured the order to build, complete, the municipal electric lighting plant for Doylestown, Pa., and several isolated plants, work upon which will begin at once.

THE D. M. STEWARD MANUFACTURING CO.

MR. D. M. STEWARD, the head of the above concern, of Chattanooga, Tenn., has reached home after a trip through the country extending over two months and including more than 2,000 miles of railroad travel. In a business point of view, it was the most successful trip he has ever made. The material used in Lava insulators is of wide applicability, and is made up into a multiplicity of articles. As an indication of this, it may be mentioned that the actual sales of Steward's patent slate pencils foot up exactly 4,000,000 pieces; while many thousand gross of "Dustless School Crayons" and other specialties made by the company were also disposed of. Mr. Steward also effected extensive sales of Lava gas tips and burners for natural or manufactured gas. As to the Lava insulators, it is worthy of record that sales were made to old and new customers in every city visited, and in many cases standing orders were increased.

At the present time, the company is enjoying a steady flow of business from mail orders, and the increase in the working force goes on steadily so as to keep pace with the growth of the industry.

A LAMP FACTORY ON WHEELS.

SUCH is a Westerner's report as to a well-known New England firm. The truth of it is that the Germania Electric Co., in moving from its old place at Cambridgeport to the larger quarters at Marlboro, had to take to the steam horse, and probably shipped as fine a lot of testing instruments and pumps as was ever assembled on a train. The gain in facilities at the new factory which is just about ready for work, will allow the firm to turn out the improved Shaefer lamps all the more promptly, and we presume George Cutter will push all the more vigorously with this, one of his specialties.

THE RIEDEL ARC LAMP.

ONE of the most interesting of the recent improvements in arc lamps is that due to the ingenuity of Mr. Josef Riedel of Marlboro, Mass. In this lamp the arc is formed at a point of uniform height and regulated by means of movable carbon holders, which are operated by an electromagnet arranged on the top part of the lamp-supporting frame, and a suitable feed mechanism, while the formation of the arc is regulated by a second electromagent that produces the separation of the carbons when the current is switched into the lamp.

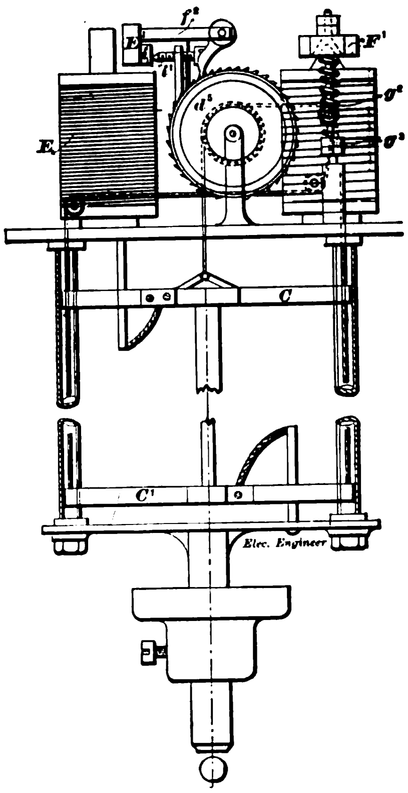


FIG. 1.—THE RIEDEL ARC LAMP.

The accompanying illustrations, Figs. 1 and 2, clearly show the method of operation, Fig. 1 being a vertical and Fig. 2 a horizontal view of the lamp. The cords d from the lower carbon holder C^1 run over the pulleys d^2 d^3 at the top of the frame, and also over a movable pulley d^4 on the armature of the magnet F. This magnet is in the main circuit, and hence, when the current is turned on, draws down the pulley d^4 and drops the lower carbon. The shunt magnet, E, actuating the ratchet wheel f, has attached to its armature a circuit breaker. The resistance of the arc, when it becomes too long, sends enough

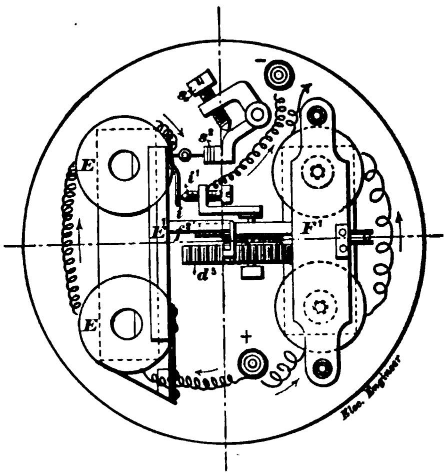

FIG. 2.—THE RIEDEL ARC LAMP.

current through the shunt to attract the armature of the magnet E and throws the circuit breaker into operation. The ratchet wheel f then slowly revolves and allows the carbons to approach each other.

Another advantage of this lamp is that its height is considerably less than most of those in use, thus effecting a saving in vertical space.

ELECTRIC HEATERS FOR STREET CARS.

AMONG those who have obtained good results this season with the Burton electric heaters is Mr. Enyart, of La Salle, Ill. His interesting letter is subjoined:

LA SALLE, ILL., Feb. 20, 1892.

ELECTRIC MERCHANDISE CO.,
W. R. MASON, Gen'l Mgr.,
Chicago.

Dear Sir: Replying to your favor about heaters, will say that during the winter 1890 and 1891 I experimented with a Burton heater, with the result that now every car on our system is heated with the "Burton Electric Heaters." I consider it the best method for heating street cars now in use, being clean, safe and cheap. I estimate that it costs us $1 per car per month for heat.

Yours truly,
(Signed) E. S. ENYART,
Supt.

A BIG WAGON FOR KERITE.

IT has remained for Supt. W. R. Brixey, of the Kerite works of Seymour, Conn., to produce the heaviest and largest vehicle of its class ever turned out. Recently returned from an extensive and interesting European tour, he brought back an idea of this rolling monster, from which has been evolved the heaviest draft wagon in America, with a freight capacity of 35 tons of kerite from the manufactory to freight depot, employing ten teams of horses. Mr. Brixey proposes to keep the wagon in steady employ hauling the output of the factory to the railroad, so that orders may be promptly filled.

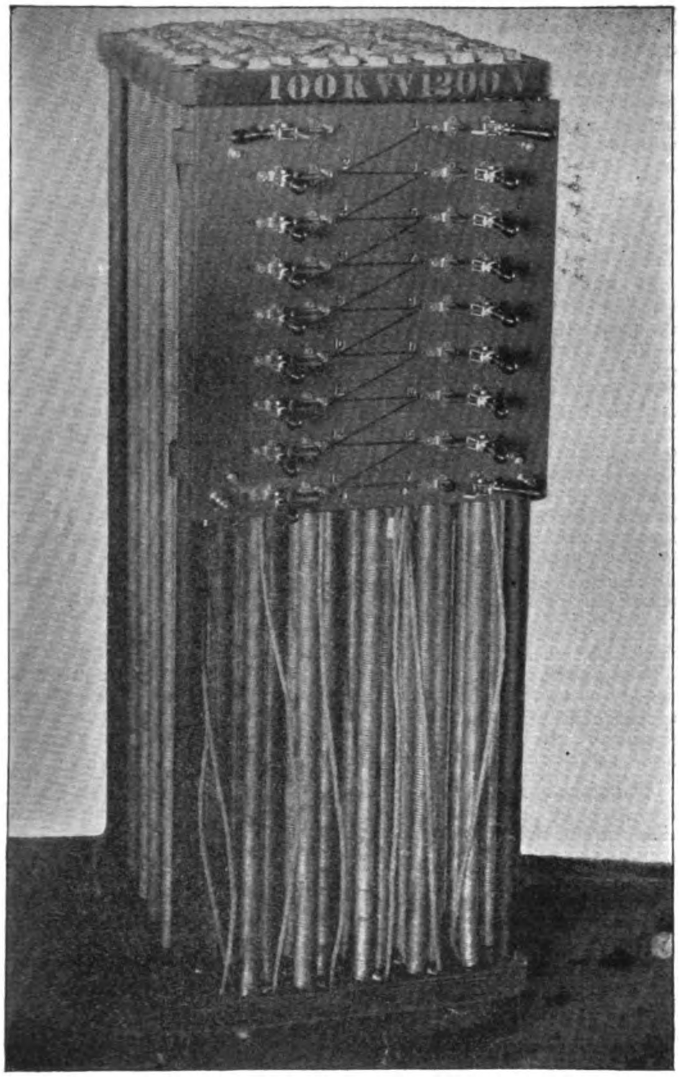
MORE WESTINGHOUSE ROADS IN NEW ENGLAND.

IN our last issue we noted the closing of important contracts at Fitchburg, Mass., and Waterville, Me., by Mr. R. S. Brown, the electric railway agent of the Westinghouse Electric Co. Mr. Brown, since then, has added some more roads to his list. He has just closed a contract for the equipment of the new palace car, which is to be put on the road of the Springfield, Mass., Street Railway Co. The car is a perfect beauty, built by Lewis & Fowler, with plate-glass windows, mahogany interior and the richest upholsterings. The Westinghouse motors, etc., will be of the best possible finish.

Another contract made by Mr. Brown is with the Worcester Consolidated Street Railway Co., for four car equipments, for that number of 34-foot cars. Each car will have two 25 h. p. motors. He is also to furnish two 20-foot cars with two 20 h. p. motors each, and one 250 h. p. generator.

THE EDISON CONTROLLING RHEOSTAT.

A NEW starting and controlling rheostat for motors running on high voltage currents has been recently designed by the Edison General Electric Company, and is clearly shown in the accompanying illustration. This is a modification of the standard Edison starting box for motors of large current capacity shown and described in THE ELECTRICAL ENGINEER of April 6, which is furnished with an ordinary switch base, fitted with a number of contact blocks and plates, arranged in a semi-circle around the pivot upon which turns the switch arm. The formation of arcs between the contact blocks, resulting in their deterioration and destruction, when the rheostats were used on high voltage circuits, constituted a difficulty which it became necessary to eliminate. The arcing could be avoided by employing a larger number of blocks on the board, but this would necessarily increase the cost of manufacture, as well as the size of the board.



NEW EDISON CONTROLLING RHEOSTAT.

The modification consists in the substitution of a switchboard with several separate and distinct switches, in place of the ordinary board just mentioned. By the employment of several separate switches it is possible to arrange the coils of the rheostat in multiple with themselves so that if it is required to carry a larger current, or remain in circuit constantly for the purpose of reducing the speed of the motor, it is comparatively simple to manipulate the switches according to requirements. The resistance is built up of tinned iron wire wound in spirals, and arranged in sections. Each of these sections can be thrown in or out by means of its proper switch. The rheostat is designed to start, and control the speed of, a 100 K. W. motor, working on a 1,200-volt circuit. The range of resistance is very wide, its greatest limit being 72 ohms, while, with the switches properly arranged it can be reduced to .25 of an ohm; the current-carrying capacity for the smaller resistance being increased in the same proportion. The over-all dimensions of the box shown, which was designed for an electric mining plant are: Height, 5 feet, 6 inches; width across switchboard, 28 inches; depth, 26 inches.

Rheostats of this design are absolutely fireproof, strong and substantial in construction, and have been arranged with a view to securing a high insulation resistance.

NEW ENGLAND NOTES.

THE FITCHBURG STEAM ENGINE CO. of Fitchburg, Mass., announce their removal into new quarters. For several years there has been an increasing demand for their engines until they were unable to keep up with their contracts, although running nights for some time. Their new factory is fitted throughout with all the best modern tools and facilities for handling large work, such as traveling cranes, etc., and is more than twice the size of their old plant. Their facilities for shipping are the best, as they can load directly from their erecting room on to the cars. They are now in shape to fill all orders promptly—for either large or small, vertical or horizontal, high speed, slow speed or compound condensing engines.

MR. C. A. BALDWIN, who has been for the past year the New England manager of the *Electrical World*, for the W. J. Johnston Company, of New York, has resigned his position with that company, to go into business with his brothers at 71 Devonshire street, Boston. They will hereafter conduct a business at that address under the title of Baldwin Brothers, and will make a specialty of handling electrical stocks, bonds and securities. Mr. Baldwin, during his year's connection with electrical newspaper enterprise, has made many friends for himself amongst the electrical trade, and enters his new duties with the good wishes of all who have come in contact with him.

THE HART AND HEGEMAN MANUFACTURING COMPANY, of Hartford, Conn., have recently been making large shipments of their well-known Hart snap switches to the West and South, and have had a great many calls for their large 75-ampere switch. This switch possesses many features of excellence. It is substantially built, and is small and compact for its capacity. A special feature of the Hart switch consists in the substantial binding posts provided, ample capacity being allowed for the reception of 000 wire, and overcoming the objection to many switches, whose binding posts are too light for the amount of current to be carried, and are not at all adapted for heavy currents.

THE CHAPMAN VALVE COMPANY, of Boston, whose factories are at Indian Orchard, Mass., have closed a contract with the Edison Electric Illuminating Company, of Boston, for the complete valve equipment of their new central station on Atlantic avenue. Their valve is specially constructed for use with high pressure steam, and is meeting with general approbation amongst electrical engineers. It will be remembered that the Chapman valve is used in the new power house of the West End Street Railway Company of Boston.

THE STANDARD ELECTRIC TIME CO., of New Haven, Conn., find a great interest aroused in their new electric tower clock, and they are having many inquiries regarding it from all sections of the country. They have recently contracted to place one of them in the new depot of the Chesapeake and Ohio Railroad at Newport News, Va. They have also closed a contract to place their system of electric clocks in the new Drexel Institute, Philadelphia.

NEW YORK NOTES.

HATZEL & BUEHLER, of 29 West Twenty-sixth street, report among recent contracts the following: To the New York Hospital, two 750-light generators of the Detroit Motor Works manufacture. This contract also includes two 75 h. p. Straight Line engines. To Austin, Nichols & Co., one 30 h. p. and one 15 h. p. Detroit motor. These, with several smaller contracts secured, have made a busy month for Hatzel & Buehler. To obtain space necessary for increasing business, this firm have secured very much larger quarters, and after May 1 will be found at 114 Fifth avenue.

THE H. W. JOHNS MFG. CO. of 87 Maiden Lane, has just issued some very neat price-list literature of its various asbestos productions for structural, mechanical and electrical purposes. It has also published a miniature color chart, which is one of the neatest advertising chromos we have ever seen. It tells what colors, tints, shades and color harmonies are, and shows the primary colors and the method of producing secondary colors from them. The company publishes also a large chart giving further information of the same kind.

THE SHORT RAILWAY SYSTEM.—The Short Electric Railway Company announce recent sales to the Braddock Electric Railway Co., Braddock, Pa.; the Union Passenger Railway Co., Chester, Pa.; the Fort Wayne Electric Railway Co., Fort Wayne, Ind.; the Schuylkill Electric Railway Co., Pottsville, Pa.

J. L. Somoff.—Rapid growth of business has compelled J. L. Somoff to institute a search for larger and more desirable quarters for the manufacture of his many novelties in incandescent lamps, surgical outfits, etc. A new catalogue is about ready for mailing, containing cuts of his decorative and other lamps and specialties. Mr. Somoff reports some excellent orders for his own peculiar style of goods from the Pacific Storage Co., of San Francisco, Cal., who are acting as his agents on the Pacific Coast. The Electric Appliance Co., of Chicago, will hereafter handle his goods also.

Ward Arc Lamps.—Noticing the many styles of lamps in the rooms of the Electric Construction and Supply Co., I was prompted to ask Manager Corey how many styles of lamps were manufactured by his company. When he answered 56, I confess I was not a little surprised. Mr. Corey further informed me that the making of these lamps for different voltages, etc., required over 500 combinations. They are having an extraordinary sale of their focusing and photo-engraving lamps, as shown at the Buffalo Convention.

Truex & Vail, electrical supplies, have taken a desirable "drop" in the Electrical Exchange Building, having removed from the sixth to the fourth floor, where they have secured a nice suite of rooms with a frontage on both Liberty and Washington streets. In their new quarters they have a good-sized laboratory and calibrating-room, in which the well-known Walker ammeters are calibrated. They report large orders for their swinging ball lightning arresters, Walker ammeters, etc., for which they are sole agents.

The New York Electrical Works have leased an entire floor at 161 Washington street, this city, and have placed therein a complete outfit of fine machinery. This company is now in a position to manufacture almost everything in the line of switches, etc., in fact, all the smaller apparatus required in electric installations. They are making a specially constructed trolley wheel made from a combination metal, which, they claim, will last at least twice as long as any wheel on the market.

Mr. A. S. Brown, manager of the Security Insulator Co., who has been ailing for a few days, is, we are glad to say, at business again. The Electric Appliance Co. of Chicago have been appointed Western agents for the Security insulator.

The Imperial Porcelain Works have opened a New York office at the Exchange Building, 136 Liberty street, Room 417. It will be in charge of Mr. C. E. Chapin, who will represent it as agent.

WESTERN NOTES.

Vincennes, Ind.—In 1886 the Vincennes Electric Light and Power Company installed their original steam plant, which consisted of two 9½ x 10 Armington & Sims engines; two 50 h. p. steam boilers, set with improved furnaces and grates; feed water heater; two Blake steam pumps, injector, etc. The company is now making arrangements to put in a 1,200-light alternating incandescent machine, for commercial and domestic service. Bids for enlarging and remodeling the power plant were invited, and a number of very elaborate plans and specifications were submitted. After long and careful consideration of the twenty proposals handed in, that of the Pond Engineering Company, St. Louis, was finally accepted, although the price asked was among the highest. It contemplates the furnishing of one 110 h. p. Armington & Sims engine and a 66 x 16 flange steel boiler, with rocking grates and Pond improved furnace; a 200 h. p. Hoppes feed-water heater, and two No. 4 Blake boiler feed pumps. The Pond Company is to deliver and erect all this machinery in Vincennes, at the same time remodeling the pipe work, so as to make a compact and well-arranged system throughout. It is expected that the new plant will be in operation early in May.

Mr. L. K. Comstock, electrical engineer, No. 427 Rookery Building, was recently called in to act for the Moline Central Street Railway Co., of Moline, Ill., in adjusting damages done by the recent fire in their plant in February, when they lost a railway generator and appurtenances. The plant was insured, and Mr. Foree Bain acted for the insurance company in the adjustment. The railway company immediately sent a representative to Chicago, where a 100 h. p. multipolar generator of the Westinghouse type was purchased. The road, during the interim, was supplied with current from the Davenport and Rock Island Railway Co., and not a single trip was lost on account of the fire.

The Woodward Storage Battery Car, which has been running regularly on the Jefferson avenue line, Detroit, is attracting a great deal of attention. With the batteries fully charged the car will run between eighty and eighty-five miles, while with the present facilities for charging, it only runs forty-two miles. Arrangements are being made to charge the car for eight hours each night, so as to render it capable of performing a full day's service. Meanwhile the car will run only during the afternoon. The Rae motor, which was lately put into this car, is giving entire satisfaction.

E. R. Gilman & Co., 140-141 Rialto Building, dealers in electrical securities, are offering at the present time first mortgage bonds of local companies at Faribault, Minn.; Neenah, Wis.; Escanaba, Mich.; Miles City, Mont.; and Colorado Springs, Col. They also have preferred income-bearing stocks for sale in the Chicago Insulated Wire Co.; the Great Western Electric Supply Co., and the Northwest Thomson-Houston Electric Co.

The Metropolitan Electrical Corporation has been formed at Kansas City, with offices at 415, 416 and 417 Whitney Building. Mr. T. F. Clohesy is the president. It intends to do a general electrical engineering business in the West, and will undertake contracts, construction, tests, etc., for all classes of light, power, storage and railway work. It will also serve as agent for a large line of light and power supplies.

Mr. John R. Markle, the well-known pioneer in electrical work of Detroit, Mich., is paying special attention to placing central stations, gas companies and similar corporations upon a sound commercial, financial basis and on a dividend-earning scale. Mr. Markle, from his long experience in fuel, gas, steam and electrical work is eminently fitted for giving reliable advice in such matters.

The Electric Appliance Company have just received their first shipment of Cutter specialties from Philadelphia and have them on exhibition at their store, where they are attracting considerable attention. The flexible bracket and portable as well as the C. S. shade are looked upon as very desirable specialties.

PHILADELPHIA NOTES.

Warren Webster & Co. report orders booked within the last few weeks as follows: Through their European Company, headquarters at Antwerp, Belgium, three orders for Webster's vacuum heater and purifier; U. S. A.—one 1,200 h. p. being second order from National Tube Works Company, McKeesport, Pa.; one 1,500 h. p. from Republic Iron Works, Pittsburgh, Pa.; one 1,500 h. p., third order from Annheuser-Busch Brewing Association, St. Louis, Mo.; one 1,600 h. p., fifth order from Cleveland Rolling Mill Company, Cleveland, Ohio; one 200 h. p. from Pennsylvania Steel Company, Harrisburg, Pa. Their factory is working to its full capacity, and the prospects of business are excellent for a very successful year. They also report that they have experienced an excellent business during the past winter with the Williames vacuum system of steam heating. They furnish catalogues free of expense, and visit plants at their own expense in any part of the United States where estimates are desired.

H. T. Paiste, the manufacturer and patentee of the Paiste switch and other specialties, has sold to the Bryant Electric Co. of Bridgeport, Conn., his patents on the Paiste single-pole switch, together with the business of the same. The transfer took place April 1. Mr. Paiste continues in the specialty line, and will introduce shortly to the electrical trade a number of new devices that he thinks will be appreciated by all.

Williamsport, Pa.—The Edison Electric Illuminating Company, whose plant is leased by Shaw & Hess, expect to make quite extensive improvements this spring, and will add another large dynamo with power to drive it. Mr. E. A. Rowley is president of the company.

R. Thomas & Son, of East Liverpool, Ohio, have purchased the entire porcelain plant formerly owned and operated by the Westinghouse Electric Company, at Pittsburgh.

The Pennsylvania Electric Engineering Company has the contract for wiring the new Hebrew Temple on Bond street for 500 lights.

The Imperial Electric Company are making a special run on porcelain insulators on which they are quoting rock bottom prices.

Mr. C. M. Wilkins, of the Partrick & Carter Co., has just returned from a pleasure trip to Florida with his family.

The Powelton Electric Light Company have added a Wood 60 arc light machine to their plant.

New Engines for Camden, Ark.—The Camden Electric Light and Power Co. write us that they have determined to buy a new 125 h. p. compound Ideal engine, and have made a contract for it.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XIII. APRIL 20, 1892. No. 207.

A CHAPTER IN AMERICAN STORAGE BATTERY HISTORY—THE DONALDSON-MACRAE STORAGE BATTERY.

THE interest taken in the storage battery at the present day, and the strenuous efforts that are being made by electricians toward its perfection, render it difficult to realize that American work in this direction is only ten years old.

It was in November, 1882, that the steamship "Labrador" brought to this country some Faure-Planté cells, made of punched sheet lead, the holes being filled and the surface covered with a paste of red lead, and the whole being wrapped in flannel and bound with rubber straps. Experiments upon these in Baltimore resulted in the production of a cell similar to the present grid type.

A patent recently issued to Messrs. Wm. W. Donaldson and Roderick Macrae, of the Donaldson-Macrae Electric Co., of Baltimore, on an improved storage battery plate, recalls the fact that these gentlemen were the first, as far as we know, to engage in accumulator work in this country. Mr. Macrae was a student at the Glasgow Physical Laboratory in 1881, when Sir William Thomson received from M. Faure in Paris the famous "black box of stored energy," which created so much interest at the time and first directed attention to the possibilities of storage batteries. In 1883, he established, with the help of Mr. Donaldson, the first distributing storage station in the United States. This station was built in Baltimore for the Electric Storage Co., of that city, and had a plant of some 200 cells, supplying current for light and power in the vicinity. In 1884 a second plant was installed; this time in the cellar of the Academy of Music, for the operation of the stage lights. These stations, situated a mile apart, were both charged on the same circuit from the local lighting station, the accumulators, being placed in series. Both these plants, after over eighteen months' work, were discontinued, as the incandescent lamps at that time were very costly, and the repairs on the batteries were excessive. On one occasion $14 was realized on the sale of platinum wire taken from lamps broken within a period of three weeks!

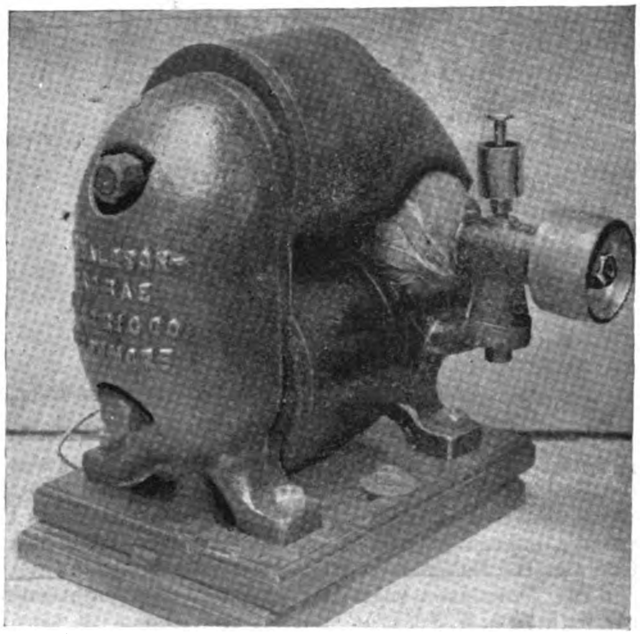


FIG. 1.—DONALDSON-MACRAE BIPOLAR DYNAMO.

Mr. Donaldson entered the field with Mr. Macrae in 1883, and in 1885 operated a car of the Daft line in Baltimore with 42 small cells. This led to other experiments in traction work, which continued for a year on an old car with a Van Depoele motor. In 1886 Mr. Donaldson took charge of the Crescent Club lighting plant, in Baltimore,

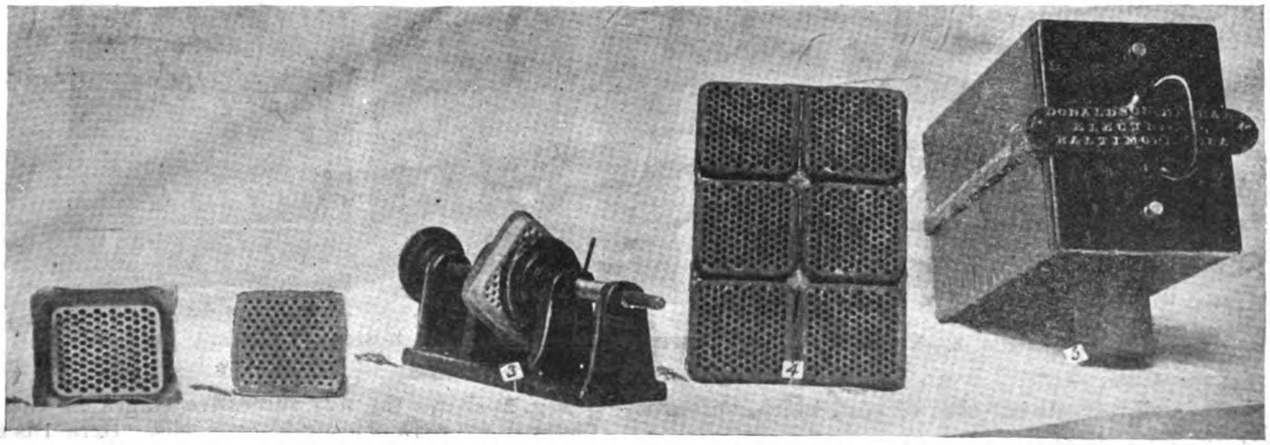

FIG. 2.—SUCCESSIVE STAGES IN THE MANUFACTURE OF DONALDSON-MACRAE STORAGE BATTERIES.

consisting of 350 one-h. p. hour cells and when, in the spring of the same year, the American Opera Company started on their Western tour, Mr. Donaldson took charge of all their electrical effects. Storage batteries were employed exclusively, 56 cells being charged about once a week in the large cities through which the company passed, and used on the "one-night stands" where current was not obtainable. After this time, during 1887 and 1888, Mr. Donaldson and Dr. Louis Duncan, of Johns Hopkins University, experimented with storage batteries for the Storage Company of Baltimore, with a view to their use in traction, and Mr. Donaldson successfully operated an eighteen-foot car with 7½ h. p. Sprague motors, climbing with ease the 7½ per cent. grades of the Baltimore streets. For eighteen months, these two gentlemen tried to get a successful thin plate accumulator and succeeded in producing one that was excellent in all respects but that of cost, which, unfortunately, was prohibitory.

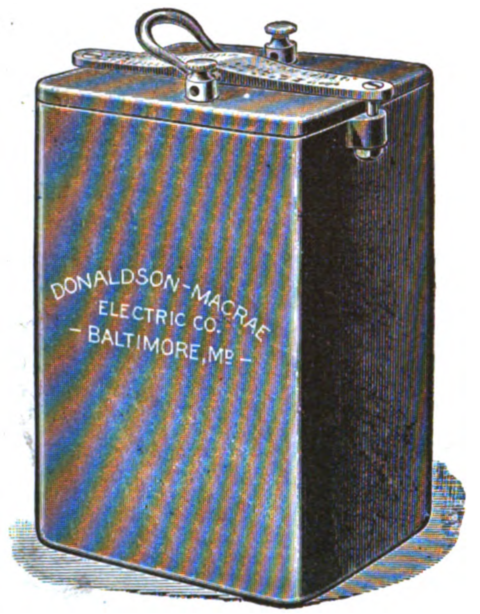

FIG. 4.—DONALDSON-MACRAE PORTABLE STORAGE CELL.

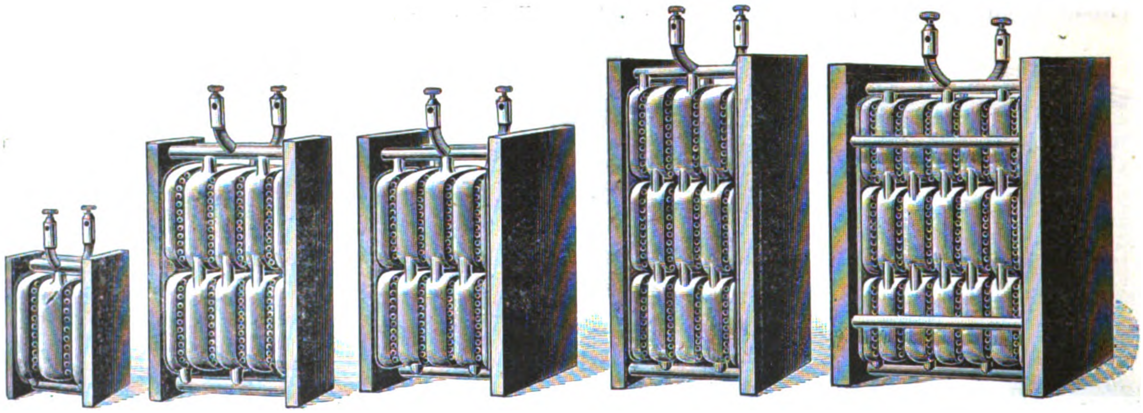

FIG. 3.—VARIOUS SIZES AND TYPES OF DONALDSON-MACRAE STORAGE CELLS.

In the latter part of 1889, Mr. Donaldson, who was then the agent for the Consolidated Electric Storage Co., started the first station for distributing storage batteries for phonographs, sewing machines, etc., the batteries being charged by the Donaldson-Macrae bipolar dynamo shown in Fig. 1 of the accompanying illustrations. This has grown until now there are over 500 cells of the Julien type in use in Baltimore and Washington, of which Mr. Donaldson has charge. Stations were afterward established in Cincinnati and Cleveland, and in January of this year the Storage Battery Supply Co., after consulting with Mr. Donaldson, started such a system in New York and Brooklyn.

Mr. Macrae has always kept abreast with the developments of storage work, and with Mr. Donaldson, incorporated in 1891 the Donaldson-Macrae Electric Co., of Baltimore. They have now perfected a battery plate which differs from all of the well-known types, being one inch in thickness and built up in sections. This type of cell has been in practical use since last August, one, according to the Columbia Phonograph Co., having run a phonograph for 100 consecutive hours. The elements of this cell weighed 33 pounds. These are now used in the Senate and House of Representatives, and also by Johns Hopkins and Washington and Lee Universities and the University of Nebraska, where Prof. Owens has 50 cells in use.

The cell is constructed by taking a standard section made by punching trays of sheet lead and filling them with active material, with holes extending from the surface up to the separation of sheet lead which is placed between two filled trays. The whole is then burned or welded together, and any number of sections are joined in one. The mode of support and clamping is most novel and a little rubber button is used to separate the plates.

The following table gives the special types of cells with their capacities and weights and the purposes for which they are especially adapted:

Type.	Cap'y. in Amp. hours.	Weight of Elements. Lbs.	Uses.
3 A	35	3	*Portable lighting.*
5 B	140	12	*Medical and telegraph.*
5 D	280	24	*Fan and sewing machine work and railroad lighting.*
5 F	420	36	*Phonograph and dental work.*
7 I	945	81	*Central station lighting and motor work.*

Fig. 2 shows the five successive stages in the manufacture of the Donaldson-Macrae cells. Here 1 is a piece of sheet lead punched and ready for filling; 2 shows a half section filled and trimmed; 3 is a view of two sections, showing the solid centre-piece in position ready for burning; 4 shows an electrode of type *E* consisting of four sections joined together, while 5 is an air-tight rubber case used for phonographic work.

Fig. 3 shows the relative sizes of the various plates, and Fig. 4 the type of portable rubber cell box adopted by the company, while Fig. 5 shows a diamond saw a rock specimen grinder operated by a motor driven by a single cell of this type.

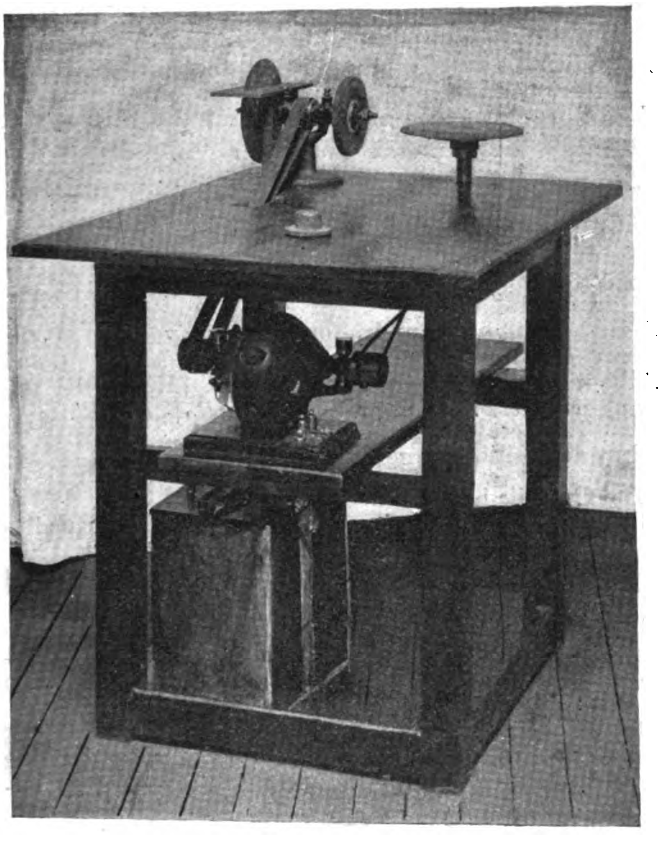

FIG. 5.—LABORATORY APPARATUS DRIVEN BY DONALDSON-MACRAE MOTOR AND STORAGE BATTERY

THE CONSUMPTION OF ZINC IN BATTERIES.

BY

F. W. Jones

IN THE ELECTRICAL ENGINEER of April 6, the answer given by Mr. Franklin L. Pope to my query in the previous number, "If 100 cells of battery in a circuit of 1,000 ohms separated as much zinc chemically as the same battery would do in a circuit of 2,000 ohms in which was included another battery of 100 cells," merely reaffirms the fact without carrying with it that elucidation so necessary to lower the conclusions of mathematicians to the plane of every-day workers in the telegraphic field. With the intention of making the subject a little clearer, I subjoin some tabulated calculations in which the cells are assumed to be one volt each, and the electro-chemical equivalent of zinc as 0.0003367 gramme, which is the weight deposited by one coulomb, that is, an ampere for one second.

By this table it will be seen that the quantity of current (amperes) in each case is in direct proportion to the number of cells in circuit. The energy (watts) is in proportion to the square of the number of cells, as is also the consumption or chemical separation of the zinc. By inspecting the table it will be seen that if one cell is working alone in a circuit of 1,000 ohms it will expend double the energy and produce twice the current and consume twice the quantity of zinc that a similar cell would do in a circuit of 2,000 ohms. In a circuit of 1,000 ohms, 100 cells will give *one hundred times* stronger current than is given by one cell *alone* in the circuit, expending 10,000 times more energy and consuming 10,000 times more zinc. Each cell working in the series of 100 will consume *one hundred times* more zinc than if it were unassisted by the other 99 cells. Yet its individual current as determined by $C = \frac{E}{R}$ is the same in either case.

The table also shows that 100 cells consume as much zinc *per cell* in a circuit of 1,000 ohms, as 200 cells consume *per cell* in a circuit of double the resistance, and that in a circuit of 2,000 ohms, 200 cells will consume 40,000 times as much zinc as one cell working alone and furnish only 200 times the quantity of current; but as the 200 cells carry into the circuit 200 times more electromotive force, as well as current $\left(C = \frac{E}{R}\right)$ therefore the product of the volts by the amperes becomes a measure both of the energy and of the necessary consumption of zinc to produce it.

A POINT OR TWO ON PRIMARY BATTERIES.

BY

Walter A. Crowdus

IN a recent article in THE ELECTRICAL ENGINEER upon the much-abused primary battery, I was pleased to see Mr. A. E. Kennelly touch upon the true basis of economy in the chemical generation of electricity, namely, *internal resistance.* The output from any cell, whether in volts, amperes or watts, as well as—if I may term it such—the "currency efficiency," are all dependent upon this one factor. In keeping with other queer things, peculiar only to the primary battery, the smaller this factor R becomes, the greater benefactor it becomes.

Not wishing to shield behind the modern maxim that nothing is impossible, or to aim a blow at superior intellects because of early incredulity, it is nevertheless a lamentable fact that the slow progress towards the commercial development of the primary battery is directly due to the subject having been taken up by electricians instead of chemists, and having been chiefly studied from an electrical standpoint, without regard to, and in many cases without an elementary knowledge of, its chemical reactions—primary to the secondary effect of volts and amperes. Is it then becoming to the electrician to condemn Nature's most powerful and wonderful secret chamber because he does not find upon its threshold the object of his search?

The primary battery thus becomes a chemical problem; but allied with it and of no less importance is a thorough knowledge of electro-chemistry; but ere we have progressed far, a third important factor, which may be said to be wholly mechanical, appears. Then we have in the most perfect battery, three subjects which must be met and disposed of to obtain true results, and our problem becomes one of no mean proportions and deserving more attention than has been allotted to it in modern times. I shall endeavor to partially illustrate how these three distinct factors influence in one way the efficiency of a two fluid cell by their direct relation to its internal resistance. The electrical books treating of primary batteries give us no light upon these points and beyond the common idea of increasing plates to increase current, nothing has been embodied in the commercial cells.

Every battery has three internal resistances, *i. e.*, three separate factors, which go to make up the internal resistance proper. I mean the chemical, mechanical and electrical resistances.

The chemical resistance is that resistance opposing the osmotic action or affinity of the separated solutions, and is represented by the pores, or holes in the separating diaphragm. A high chemical resistance has always been considered to entail a high electrical resistance; this I have discovered is not necessarily so.

The mechanical resistance is the solid particles of the separating diaphragm. A high mechanical resistance necessarily gives a high chemical resistance, and has in all existing batteries effected a high electrical resistance. This last, I have proved, is not necessary.

The electrical resistance is the combined resistance of the excitant and depolarizer interposed between the positive and negative elements; hence the larger the elements, the lower the resistance of the liquid; or the closer the elements, the lower will be the liquid resistance. (A small electrical resistance may exist in the elements themselves.)

As a deduction from the above, the most perfect battery would be one having the highest possible mechanical and chemical resistance and the lowest possible electrical resistance; the results would be, no local action, no waste on open circuit and a very small R, while the output of any existing cell would be increased fivefold, with a like increase in its "currency efficiency." In short, internal resistance in a battery is the same as friction in moving machinery, and though the statement may seem incredible to some, it is true that of two cells performing equal work in any external circuit, and having, respectively, an internal resistance of one and four ohms, the latter will dissolve four times as much from its positive electrode as the former, will require four times the quantity of excitant to oxidize it and demand four times the quantity of oxygen to take care of the liberated hydrogen. The one is spending its force exterior to itself; the other is consuming three-fourths of its energy before reaching the external circuit. I might add that a certain open circuit battery upon the market owes its merited success largely to its low internal resistance. Hence, the efficiency of a battery is expressed by dividing the resistance of the external circuit R' by the sum of the internal R and external resistance, *i. e.*, efficiency $= \frac{R'}{R + R'}$.

This should also disprove the popular idea that the resistance of the external circuit should be the same as the internal. A trial will show the battery would then be working at an efficiency of only 50 per cent. by the above rule, and, introducing heat loss, it becomes even less. Such practice is not followed in any other applied science. This R, generally regarded of no moment, is the most expensive luxury when we pay for the chemicals it consumes. Accompanying the neglects I have cited, I have found that users of primary batteries have been wholly without laws, rules, or formulæ by which they could intelligently gauge the size or number of cells suited to a given circuit; and fairly good batteries have brought sorrow to the purchaser and discouragement to the poor inventor because of faults exterior to the cell. Like the mule, the primary battery has been abused on general principles. With a hope that I may benefit some, I give below some simple equations based on Ohm's law, which can be used to eliminate all errors and guessing, and, if correctly applied, cannot fail to bring about good results.

The difference between the gross E. M. F. of a battery and the difference of potential it can maintain in any exterior circuit is strictly proportional to the resistance of the several portions.

Let E represent the gross E. M F. of the battery; C, current through its own resistance; R, its internal resistance. By Ohm's law $C = \frac{E}{R}$, and $R = \frac{E}{C}$. This same law applies to the external circuit. Hence we get the second equation, $C' = \frac{E'}{R'}$; whence, $R' = \frac{E'}{C'}$; in which E' is the fall of potential, or available voltage in the external circuit; C', the current in the external circuit, and R' the resistance of the external circuit. Hence the following proposition holds good, $E : E' :: R + R' : R'$.

By transposition we get $E' = \frac{E \times R'}{R + R}$.

The first rule is written thus:

RULE 1: The available voltage of a battery is equal to the product of its electromotive force and external resistance divided by the sum of the external and internal resistances.

In the above equation it is necessary to know the resistance of the external circuit. If this is not known the current in the external circuit can be taken and the equation written: $E' = (R \times C') - E$.

To find the value of R' we have:

RULE 2: The external resistance is obtained by dividing the electromotive force by the current in the external circuit and subtracting the internal resistance: $R' = \frac{E}{C'} - R$.

To find the value of C' we write:

RULE 3: The current in the external circuit is equal to the electromotive force divided by the sum of the external and internal resistances: $C' = \frac{E}{R + R}$.

Thus, knowing any two factors of a given cell we can calculate the values of any number of cells for any circuit without the use of voltmeter or ammeter.

PHOTOGRAPHING BULLETS.

In a lecture on this subject, delivered recently at the South Kensington Museum, Prof. C. V. Boys explained his apparatus for the purpose. It consists of a box lined with black cloth, in which the photographic plate is exposed; of a condenser formed of a plate of glass about a foot square; of a smaller condenser in the form of a bottle, to act as a starter of the spark; and of a system of wire circuits and knobs to give the spark which throws the shadow of the bullet on the plate, and thus takes the photograph. The bullet enters and leaves the box by two holes, covered with paper to exclude the light; and in passing the plate the bullet touches the terminals of two wires, composed of thin lead wire, thus partly completing the circuit; a small flash passes from the smaller condenser, causing a larger flash to pass between the knobs of the plate condenser inside the box; and this flash lasting less than one-millionth of a second, takes the photograph of the bullet, no lens being employed. A wet string in the circuit of the small condenser is used to damp the electrical oscillations. Mr. Boys was able to infer from his experiments with a rifle that the bullet must have received some three per cent. of its velocity after leaving the muzzle, at which point the turning effort of the rifle must have necessarily ceased.

"KOBOLDS" IN ELECTRO-DYNAMICS.

BY

Fred A. Schaffler

THE mechanical or electrical experts who read this article will become aware that the writer's purpose is not to advance whys and wherefores with a view to promulgate a new term for applied electro-dynamics, although the word should be applied to the *investigation* of such science, and it behooves me to show cause for such a statement. To those who are uninitiated I will explain that a "kobold" is any mysterious occurrence which takes place when you least expect it. For better comprehension one example will suffice. When you are in a desperate hurry to finish dressing, you lose your collar button, and as this invariably happens at exactly the wrong time, and you hunt, not high, but low for it, under the bed, dresser, in your slipper, and every place but the right one, you are much vexed thereat. That's a "kobold;" and they permeate everything, and anything, but seem to be more prevalent in electrical investigations, experiments, etc., than in any other branch of science or manufacturing business, according to one person's experience at least.

There are two kinds of kobolds; good ones and bad ones; but more particularly do they assume characters which are extremely bad. Occasionally you will meet a little fellow cropping out through some experiment which leads you to become effusive over the recent discovery. Further and prolonged investigation only tends towards showing you how egotistical you are, and how with much nursing the promising kobold develops into a veritable demon of improper proportions and of disappearing qualities and quantities. There is only one family of kobolds in electro-dynamics, but they are known by many names, such as short-circuits, open circuits, grounds, "niggers," improper armature and field windings, disproportion of armature core to field, swinging ground, sparking and flashing at commutator, loose connections, etc.

Sometimes the more promising young kobold proves himself to be of first-class character, and your investigation, invention, theory, or whatever it may be that you are at work upon really develops into a result which is most practical and useful.

It is more than certain that the most obnoxious and expensive kobolds (there is always more or less expense attached to the "funeral" of any kobold) have and do make their appearance in storage batteries. Sometimes in this part of electrical affairs two years elapse before they become fully developed, but from the time the battery or cell is finally constructed they are there in embryo.

Armatures, converters and street car motors seem to be more particularly afflicted with abominable kobolds, when in daily use, than, perhaps, any other apparatus of applied electro-dynamics. In street car motors the unsophisticated driver, or "motorneer," as he is sometimes called, can in twenty seconds by a simple twist of the wrist produce the most frightful kind of a kobold. I do not mean to say that the development occurs before the driver returns to the car shed, but rather afterwards, when he explains how he is not responsible, and that everything happened when the car was running so nicely, etc.

It is exceedingly strange that some, if not all, of our most prominent electricians can and have produced very discreditable kobolds, and the cost of rectifying the same would, if properly accounted for, furnish a first-class endowment for a university where the practical application of the science of how not to do it could be taught to great advantage. We would all very much enjoy reading an account of the experience with kobolds of some of our prominent electricians—men who have had much acquaintance in matters of both theoretical and practical nature. Such a recital would do us all good, and would surely give us something wherewith to whet our solicitude for all matters of an electrical nature, and create within us a new desire to live down any disconsolate feelings we may have, for we would then have in black and white statements which show that others who have more knowledge of the science have also been blessed with obstinate and surprising kobolds.

Prof. Sweet, of Syracuse, some time ago presented a paper to the American Society of Mechanical Engineers, entitled, "The Unexpected which Always Happens," and it was the writer's original intention to give this article the same title, but also to add "No. 2." The word "kobold" is much shorter, and when you grasp its actual meaning is fully as comprehensive as the more lengthy expression above mentioned.[1]

Sometimes these kobolds will persistently follow all attempts to attain certain ends, and this usually occurs when the ends sought after are required for immediate use, or not at all. I will instance a series of delays and misfortunes which occurred to a prominent electric company last fall when preparations were being made with a view of presenting a fine exhibition at the Convention of the Street Railway Association at Pittsburgh, and in which the prince of kobolds himself gave personal attention to the preparations, with a very evident intention of preventing such an exhibition being given, at any cost. Arrangements for this representation were begun fully six weeks previous to the opening day, and this time would have been ample under ordinary circumstances. The principal apparatus to be exhibited consisted of three machines, a new waterproof single-reduction motor, the great and only gearless motor (which for the first time was to be shown in all its glory to street railway magnates promiscuously, and placed in daily operation for open-handed and fearless investigation) and a new, latest improved 200 h. p. generator. The first of these was an entirely new type of motor, and the entire machine had to be built from beginning (patterns, etc.,) to end, in the time allotted, six weeks. Work progressed finely until one week before the convention was to be opened. Then the first kobold made his appearance. He was only a little fellow compared with his relatives whose acquaintances were made that week, in which there were only the usual six working days, *and nights.* The motor was at last finished, except the testing, and every one interested felt lighter hearted. Current was delivered to the motor and the test began. Didn't the machine run beautifully? Weren't all competitors to take a back seat when the prize "S. R. G." was exhibited? Fizz ! !! !!! !!!! The armature still revolves, but the commutator will soon be "burnt up" if the current is not open-circuited. An examination shows that owing to the haste made by an armature winder, a defect in insulation had caused several bobbins to be short-circuited, and a burn-out occurred. It will require one day and one night to kill that kobold and complete the armature for test again. This test was made, and only four days remained before the exhibition was to be opened. Two more changes were required, then the motor would be completed at last. Nothing further occurred to interfere and the motor was sent on its way to play a prominent part in the railway exhibition.

---

[1] An article, which the writer came across entitled "Kobolds; there are such things," from the *London Globe* in *Current Literature*, was the first intimation I had of their existence, but the subject was especially applied to their relation to humanity. The specific origin is, of course, the little imp in Norse literature, corresponding, I presume, to the "Brownie" in ours

In the meantime work was progressing on the gearless motors and generator. To cut a long story short, after many more interferences from outside and unseen enemies, the gearless motors were completed. Each kobold delayed making its appearance during the six weeks until three or four days preceding the latest possible time for shipment of the apparatus. The generator proved to be proof against any kobold attacks of an electrical nature, but the prince above referred to made his presence known just at the time of shipment. The party who had the contract for loading the generator had previously handled eight machines of the same size without any accident whatever. Why should anything happen to this particular one, especially when there lacked only three days before convention time? The only explanation is that kobolds sometimes get into a man's head, where they can do as much damage as they can in a more in animate object. Suffice it to say that the "boss" had concealed in his pocket a bottle of Jersey lightning, and although he was perfectly sober when he came to the works to haul and load the generator, he in due time became, by long and frequent draughts of the liquor, so intoxicated that his assistants played give and take with him in language more expressive and emphatic than gentlemanly. By this time the generator was ready to be hauled off the rear of the truck on to the end of the car, and the switch engine was waiting to pull the car out. Through careless placing of the rollers under the generator, as soon as the tackle was made taut, the big box, containing 20,000 pounds, fell off the truck and came to rest in a good many pieces, with the generator upside down on the sidewalk; and it was half past six at night! The machine fell in such a position that it was impossible to pull out the car containing the exhibition motors and truck, as one corner of it obstructed the track. The services of the drunken teamster and his outfit of assistants were immediately abandoned, and by using "jacks" and the help of many hands the generator was moved sufficiently to permit the car to be pulled out. All that night a force of men were at work placing the machine right side up and returning it to the shop for repairs. Here, upon investigation, another surprise occurred. Every one interested fully expected to find that expensive injuries had been sustained, considering the fact that the generator had fallen five feet, but beyond bending a few trimmings and jamming of magnet heads and smashing the packing box, nothing was damaged! The machine was again packed and shipped the evening following the accident, and arrived at the exhibition in time to demonstrate that certain kinds of dynamos can be almost as roughly handled as a portable boiler in the oil regions.

The imp of a kobold followed that generator to Pittsburgh, however, where it fell off the truck twice while being conveyed from the freight depot to the never-to-be-forgotten exhibition barge, and many eyes watched it with misgiving, fully expecting that the final roundup of adventures would be the dumping of the generator into the Monongahela River.

These kobolds, after all, have their mission, and serve only to make us become more watchful and to more carefully consider the pros and cons of our design or work, or whatsoever we may be engaged in. Experience is a faithful teacher, but we do not like to get it so frequently in the shape of a *cave canem* manner.

In a recent report to the Counseil Municipal of Paris, M. Paul Brosse gives some statistics with regard to the relative positions of gas and electricity in that city. The consumption of gas continues to grow, although the rate of increase is somewhat less than it was. The Paris central stations have at the present moment a plant capable of developing 17,500 h. p.; when complete this figure will become 32,000. During 1891 the gas consumed in Paris amounted to 10⅓ million thousand cubic feet. Out of 85,000 houses only 20,000 are fitted with gas.

ON THE MEASUREMENT OF THE POWER GIVEN BY ANY CURRENT TO ANY CIRCUIT.

BY

Norman Whichello.

Most electricians have, no doubt, seen an account of Prof. Ayrton's 3-voltmeter and 3-ammeter method of measuring the power given by *any* current to *any* circuit. To those familiar with calculations dealing with alternating currents, such a method would at first sight seem an impossibility in the case of an alternating current which is not a sine wave but some unknown function of the time, and still more so in the case of a more complex current such as an intermitting current. Although I have frequently seen the results stated, I have never been able to get hold of a proof, and have accordingly investigated it myself, and find that the proof is very simple when once on the right track. As many of the readers of The Electrical Engineer may be similarly situated, I think the proofs given below may be of interest.

The whole principle of the proof depends on one leading fact. We are all familiar with the fact that the product of the mean values of two variables, is not the same as the mean value of their products. If it were, we should simply have to multiply ammeter and voltmeter readings together to get the watts given by an alternating current to an inductive circuit. It *is* true, however, that the sum of the mean values of two variables is equal to the mean value of their sums.

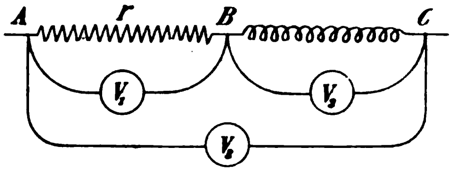

Fig. 1.

An example may make this clearer. Let x and y be two variables, and let them assume the values given below. The values of x are 1, 5, 6, and the simultaneous values of y, are 2, 3, 1.

The mean value of x is evidently 4 $\left[i.\ e., \frac{1+5+6}{3} = 4\right]$

and the mean value of y is evidently 2 $\left[i.\ e, \frac{2+3+1}{3} = 2\right]$

∴ the sum of the mean values of x and y is 6 [*i. e.*, $4 + 2 = 6$]. Now the separate sums of x and y are 3, 8, 7 [*i. e.*, $1 + 2 = 3$, $5 + 3 = 8$, $6 + 1 = 7$]. And the mean of these is 6 $\left[i.\ e., \frac{3 + 8 + 7}{3} = 6\right]$. Therefore the sum of the mean values of two variables *is* equal to the mean value of the separate sums - - - - - - - - - (1)

And the reader can easily see by trial that the same is true of the difference, *i. e.*, the difference of the mean values of two variables is equal to the mean value of their differences - - - - - - - - - - - (2)

The results (1) and (2) follow immediately from the fact that $(x + y)\ dt = x\ dt + y\ dt$. Now consider the products. The mean values are as before 4 and 2 and their product is 8. Their separate products are 2, 15, 6 [*i. e.*, $1 \times 2 = 2$; $5 \times 3 = 15$; $6 \times 1 = 6$], and the mean of these is $7\frac{2}{3}$ $\left[i.\ e., \frac{2 + 15 + 6}{3} = 7\frac{2}{3}\right]$.

Hence the product of the mean values of two variables is *not* equal to the mean value of their products - (3)

The same is true if we read ratio for product - - (4)
The results (3) and (4) follow from the fact that $(x\,y)\,dt$ is not equal to $x\,dt \times y\,dt$.

We can now deduce the expression for the power. The circuits are joined up as indicated in Fig. 1. Here B C is the circuit, the power given to which we wish to measure. A B is a truly non-inductive resistance of r ohms $V_1\ V_2\ V_3$ are the readings of three Cardew or other suitable voltmeters. $V'\ V''\ V'''$ are the corresponding instantaneous values of the P. D's. Now $V' + V'' = V'''$, although of course $V_1 + V_2$ is not equal to V_3. Also V_1^2, V_2^2, V_3^2 are the mean values of $V'^2\ V''^2\ V'''^2$ respectively, assuming, of course that the alternations are rapid enough to prevent the needles from oscillating with the P. D. And this will be true however complex the wave of P. D. may be.

The power being supplied at any moment to B C is $C\,V''$, C being the instantaneous value of the current. This is the product of two variables, and (4) tells us that its mean value is not $V_2 \times$ the effective current. If, however, we can throw this expression into the form of sums or differences, or both, instead of a product, then we can use (1) and (2) at once. This, fortunately, is easy.

$$C = \frac{V'}{r} \text{ since A B is non-inductive.}$$

$$\text{Therefore } C\,V'' = \frac{2\,V'}{2\,r}\,V''$$

$$= \frac{1}{2\,r}\left[V'''^2 - (V'' + V')^2 + 2\,V'\,V''\right].$$

$$\text{since } V''' = V'' + V'$$

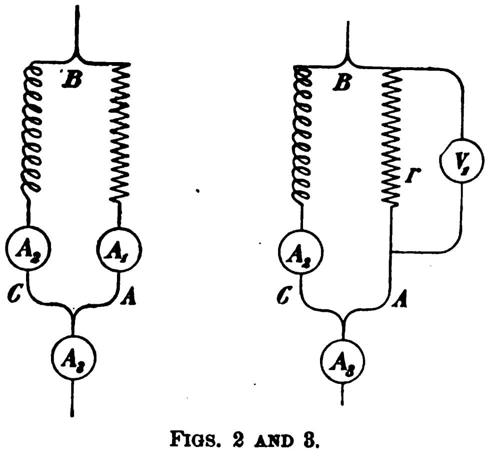
$$\text{reducing} \qquad C\,V'' = \frac{1}{2\,r}\left[V'''^2 - (V''^2 + V'^2)\right]$$

and this *is* in the derived form of sums and differences. Therefore the mean value of the power given to B C is $\frac{1}{2\,r}\left[V_3^2 - (V_2^2 + V_1^2)\right]$ which is the expression given by Prof. Ayrton.

The three ammeter method may be proved in exactly the same way. In Fig. 2, B C is the circuit the power given to which we wish to measure. A B is the non-inductive resistance of r ohms. $A_1\ A_2\ A_3$ are the three ammeter readings.

It is very easy to see that the mean value of the power given to B C is $\frac{r}{2}\left[A_3^2 - (A_2^2 + A_1^2)\right]$.

If it be objected that A B cannot be truly non-inductive because the ammeter A_1 must necessarily have self-induction, we may replace A_1 by a voltmeter, as shown in Fig. 3. $\frac{V_1}{r}$ of course takes the place of A_1 in the formula.



FIGS. 2 AND 3.

The second method is superior to the first in that it does does not require the dynamo to give a higher P. D. than the P. D. on B C which makes the method convenient for testing the efficiency of a converter in situ, B C being the primary side of the converter; it is inferior to the first in that it requires three instruments, whereas in the first case a simple arrangement of keys or mercury cups enables one voltmeter to give all three readings.

While on the subject of measurement of the power it might be well to speak of the electrometer method, as this also can be shown by the aid of (1) and (2) to measure the power given by *any* current to *any* circuit.

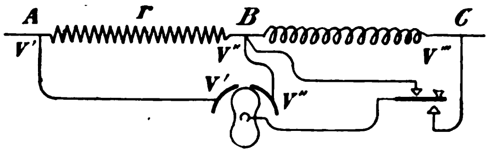


FIG. 4.

The circuit is joined up as shown in Fig. 4, r being the non-inductive resistance in series with the circuit the power given to which we wish to measure. The pairs of quadrants [one member only of each pair is shown in the sketch] are connected as indicated. The needle can be connected to either end of the inductive resistance by a key. $V'\ V''\ V'''$ are the instantaneous potentials of the points indicated. $D_1\ D_2$ are the deflections of the electrometer when the key is depressed and raised respectively. $D'\ D''$ are the instantaneous deflections which we should have if the electrometer were dead beat enough to follow the alternations.

The law of the electrometer is

$$D = k\,(V' - V'')\left(V - \frac{V' + V''}{2}\right)$$

where V is the potential of the needle and k the constant of the instrument. If we depress the key, $V = V'''$

$$\text{and } D' = k\,(V' - V'')\left(V''' - \frac{V' + V''}{2}\right).$$

If we raise the key, $V = V''$

$$\text{and } D'' = k\,(V' - V'')\left(\frac{V' - V''}{2}\right)$$

$$= \frac{k}{2}\,(V' - V'')^2;$$

$$D' - D'' = k\,(V' - V'')\,(V''' - V'')$$

Now if C is the instantaneous current $V' - V'' = C\,r$ since r is non-inductive.

$$\therefore \frac{D' - D''}{r\,k} = C\,(V''' - V'') = \text{instantaneous power given}$$

to inductive circuit.

$\therefore$ The mean value of the power given to the inductive circuit is the mean value of $\frac{1}{r\,k}\,(D' - D'')$ and this is in the form of a difference; hence we may apply and say simply the mean value of the power given to the inductive circuit is $\frac{1}{r\,k}\,(D_1 - D_2)$.

So far as I know these are the only satisfactory methods yet suggested for the measurement of the watts developed by an actual alternator as built to-day.

UNDERGROUND MAINS IN PARIS.

ACCORDING to *L'Industrie Electrique*, the Compagnie Continentale Edison has had difficulties with its underground mains. The type of conduit originally adopted was very similar to the Crompton system, but want of space precluded its universal use. The company, therefore, looked out for a system which, while occupying less space, should still allow of bare copper conductors being run everywhere. At this juncture Jacob Frères, of Pouilly-sur-Saône, suggested rectangular earthenware troughs. These were used in places, and at first gave good results. After a time, however, the insulation fell, owing to infiltration and chemical action, and the Edison Company has now reverted to its first plan.

THEORETICAL ELEMENTS OF ELECTRO-DYNAMIC MACHINERY.[1]—I.

BY

A. E. Kennelly

MAGNETISM is the science that deals with a series of phenomena whose ultimate nature is unknown, but which result from, or are at least accompanied by, a particular kind of stress. This stress may reside in matter or in the air-pump vacuum. The magnetic metals, iron, nickel, and cobalt, when submitted to this stress, not only intensify it in their own substances, but are strained in such a manner as to sustain the stress independently to a greater or less degree after the existing cause has been withdrawn. In other words they become magnetic and remain magnetized.

The only known sources of magnetic action are three, viz., electric currents, electrical charges in translatory motion, and magnets.

Any magnetized space, or region pervaded by magnetic stress is a "magnetic field," but the term is commonly applied to the space which separates the poles of an electromagnet. The existence of stress in the field is evidenced in several ways:

1. By the magnetic attraction or repulsion of magnetized substances introduced within the field.
2. By the influence exerted on the molecular structure or molecular motion of a number of transparent substances whereby the plane of propagation of luminous waves is rotated in traversing them.
3. By the electromagnetic energy which is found to be absorbed by the medium during the establishment of a magnetic field, stored there while the field is maintained, and released at its subsidence.
4. By the electromotive forces that are found to be generated in matter moved through the field.

These experimental evidences point to the action of magnetic stress pervading the magnetized medium. Moreover the stress never terminates at an intersecting boundary, but follows closed paths. A line of stress is a closed loop like an endless chain. If a small compass-needle were introduced into a magnetic field, and kept advancing from point to point in the direction it assumed at each instant, it would finally return to the position from which it started. This can only be shown in the case of fields established by electric currents in wires, or coils of wire, as the needle could not complete its circuit through the mass of an iron magnet. The circuital distribution of the stress indicates its appurtenance to the category of fluxes. That is to say, in any magnet, or magnetized region, there is a distribution of influence analogous to the flow of current in an electric circuit, or the flow of water in a closed pipe or re-entering channel. The marked distinction, however, between the flow of magnetism, and the flow of electricity or of fluid material, lies in the fact that no work is done and no energy exchanged in the passage of the magnetic current. The electric current and the moving liquid encounter resistance and develop heat in moving against that resistance, but the magnetic flux acts as electrical currents or material currents might act if unchecked by resistance but regulated in quantity by other limitations; and if water were itself frictionless and were set circulating in a closed frictionless pipe, it would necessarily continue in perpetual motion. It of course by no means follows that any circulating motion of matter or of ether actually takes place in a magnetic circuit. That there is a possibility of such motion is a consideration left to the theory of the ultimate and fundamental nature and origin of magnetism. All that is essential to the conception of a magnetic flux is a continuous stress acting along a closed path or circuit, such that a single magnetic pole (if such could exist alone, or let us say as the nearest representation in fact, one pole of a long bar magnet) were introduced into this path it would be continually urged round the circuit.

Flux in a magnetic circuit, just as in a hydrostatic, or electric circuit, possesses at each point intensity as well as direction, and can therefore be completely specified by a vector. According to the conventions etablished in the absolute C. G. S. system, a field of unit intensity will exert unit pull or one dyne, upon an isolated unit magnetic pole introduced therein. The intensity of the earth's magnetic flux is approximately 0.6 unit in the open country around New York, and consequently, a single north-seeking or unit pole suspended in that neighborhood would be drawn downwards in the direction of the dipping needle with a force of 0.6 dyne, which would represent the weight of nearly 0.6 milligramme (a dyne being about 2 per cent. greater than the earth's gravitation pull on a milligramme of matter). Practically it is impossible to obtain an isolated unit pole, but it is quite possible to measure the pull exerted by a magnetic field upon some definite system of electric currents or magnets, and to deduce what the corresponding pull would be on a unit magnetic pole. This would be the numerical intensity of the flux in the neighborhood of the point considered. Flux intensity is denoted by the symbol B, and is, strictly speaking, a vector denoting direction as well as magnitude.

The direction of a magnetic flux is the direction in which it would move or tend to move a free north-seeking pole. The north or blue end of a small compass needle points in the direction of the field surrounding it. According to this convention it follows that the earth's flux is from the geographical south towards the geographical north pole. Also, to follow the direction of a flux, is to move along it in a positive direction, while to oppose it is to move negatively.

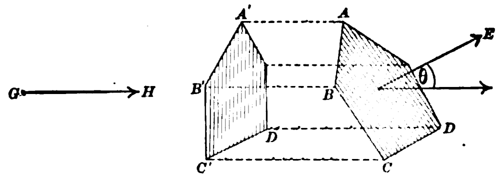

FIG. 1.

The total quantity of flux that will pass through a given normal plane area, is the product of that area and the intensity when the latter is uniform. For example, a plane area of say 150 sq. cms. held near New York perpendicularly to the direction of the dipping needle will contain 150 x 0.6, or 90 units of flux. In ordinary language it will contain 90 lines of force or of induction. The word induction, however, from frequent misapplication is apt to be so ambiguous that it is advantageous to dispense with it in this sense.

If the intensity varies from point to point, the total flux will be the average intensity over the surface multiplied into the area. If the plane area does not intersect the flux at right angles the flux enclosed will be the average intensity multiplied by the area of the boundary as projected on a plane intersecting perpendicularly, which might be termed the equivalent normal area. This is shown in Fig. 1 where ABCD represents an arbitrary boundary drawn on a plane surface whose normal E makes an angle θ with the vector GH, and this vector represents the uniform flux intensity in direction and magnitude. The total flux enclosed by ABCD will be the product of the length GH into the area A' B' C' D' which is the projection of ABCD on a plane normal to GH. Calling the area ABCD a, φ the total flux, and B the intensity, it is evident that

$$\varphi = a\, B \cos \theta$$

Finally if B, instead of being uniform throughout the space covered by the area, varies from point to point, the total flux could be found by dividing the areas into a sufficiently large number of small portions, determining the values of θ and B for each. By taking the area small enough, θ and B would be more and more nearly uniform within the limits of each, and the flux through each could then be determined separately. The sum of these fluxes would be the total flux enclosed by the whole boundary area. In other words the total flux would be the surface integral of the normal intensity all over the area as expressed by the equation

---

[1] *Copyrighted* 1892 *by A. E. Kennelly.*

$$\varphi = -\int S.\ Bn\ ds.$$

This general result is independent of the form of the surface round which the boundary is described. This surface may be plane, warped, or convoluted.

As an example, consider the spherical surface represented in Fig. 2. Let this surface be definitely located in any permanent field—in a flux that does not vary with time—but which may be quite irregular in intensity. We may assume that the vector B is known or can be determined for every point. Draw any closed line CDEG round the sphere. Then if this sphere does not enclose any source of magnetism—current or magnet—we may follow out the plan above indicated and take the surface integral of flux: (1) over the lesser spherical area CDEGH; (2) over the greater spherical area CDEGK; (3) over a surface stretched tightly across the boundary; or (4) over any conceivable surface into which the diaphragm CDEG could be expanded. The result will in each case be the same total flux, if due precaution be taken to attach + signs to emerging + flux, and — to an entering + flux. Any element of flux not passing through the boundary must then cut the surface an even number of times half in entrances and half in emergences, and the summation of these elements having opposite signs will cancel out from the result in pairs.

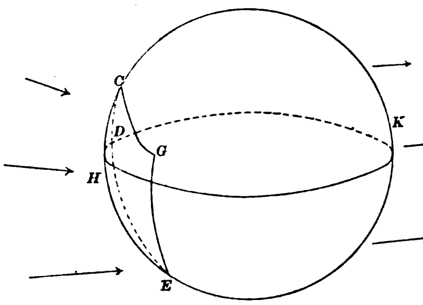

FIG. 2.

This proposition, capable of indirect experimental verification, is tantamount to the statement that magnetic flux neither expands nor condenses in its passage through bodies, however its direction or intensity may vary. Because the flux which is steady in regard to time must be entering into and emerging from any portion of space at the same rate, unless at that moment, expansion, condensation, generation, or annihilation be taking place within the confines. In the above instance of Fig. 2, it is evident that the flux which enters the area CDEG in the direction of the arrows must be issuing from the volume CDEGK at the same rate if accumulation or dissipation is not at work within, and the quantity which in any given time issues from the spherical surface without having also entered there must have come in through the boundary CDEG. In this respect magnetic flux behaves like the flow of an incompressible fluid.

"CANNOT AFFORD TO MISS ONE."

A SUPERINTENDENT of construction for one of the parent companies, who happens to be at work just now in Pennsylvania, writes us to give his address, and says: "I have not received last week's copy of your paper. It is so valuable to me I cannot afford to lose even one."

THE ELECTRIC MOTOR IN AGRICULTURAL WORK.

BY

A. A. Denton

IN a previous communication,[1] the writer pointed out the great desirability of employing electricity as a general motive power in agricultural work, and showed how, by the use of the electric motor larger crops could be sowed and harvested than are now attempted and with a reduction in cost to the farmer. Since then an experimental trial of a 5 h. p. motor has been made here, simply to learn the points of the motor, and to learn the difficulties which may be met in adapting it to field work.

When the experiment with the electric motor was begun here, it was supposed that the difficulty of a movable wire connection of the motor with the dynamo would be formidable. It is believed that this difficulty can easily be met; the motor, as it moves over the field, easily moves the trolley line. The difficulty of traction, or adhesion of the driving wheel of the motor car, is greater, for a 25 h. p. motor weighs no more than one good horse, and exerts far greater pull. It is obviously not desirable to add dead weight to increase traction, but whenever a difficulty is clearly recognized and measured, ways are found to obviate it; this is the history of all progress.

There is now very great interest in the matter of utilizing mechanical power in cultivating the great prairies of the West. Several steam plows are now being set up in this State, and it is hoped that accurate data in regard to the use of direct traction steam plows may be had this season. So far as I am able to learn, indicator cards of the engine and dynamometer tests of the plow-gang have never been taken to show the proportion of useful effect to the power developed in the steam plow.

Senator Peffer, of this State, has introduced a bill to provide for the establishment of an agricultural power experiment station by the Government, in which an effort may be made to determine the relative values of the different motors on the great grain-growing farms of the plains. It seems that the Department of Agriculture may, by employing expert skill and sufficient means, determine points of value to the country. Senator Peffer's bill has been referred to the Committee on Agriculture and Forestry, and will soon be considered by that committee.

The Senator would be pleased to have the points of the electric motor, with reference to its supposed fitness for agricultural work, to use in argument before the committee. The experience of your readers and their knowledge of power machines, of the comparative efficiency of animal power and of the electric motor in street railway work, may materially aid the Senator in securing the establishment of an agricultural experiment power station. Let THE ELECTRICAL ENGINEER aid in this matter, and oblige the hundreds of thousands who are interested in the solution of the problem of power on the farm. James Watt said to the King of England, "I have what every subject of your majesty wants—power."

Western agriculture requires power by which one man may accomplish as much as many men in the old way—power to cut wider and deeper and swifter furrows at less cost than in the old way. Manufactures and commerce and mining have the advantage of ample and cheap power; agriculture alone is limited to animal power. If the motor may be be adapted to farm work, Western agriculture will enter a new era. The great plains appear to have been planned for cultivation of the soil on a large scale.

DEPARTMENT OF AGRICULTURE, STERLING, KAN.

"MY OPINION OF YOUR PAPER."

A READER in Baltimore writes us: "I would state that I *take* several electrical papers including yours; I *read* the ENGINEER."

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, APRIL 20, 1892. NO. 207.

The history of progress is full of examples of able men following a wrong road from ascribing effects to that which in the end has proved not to be the cause.—Coleman Sellers.

WIRING INSPECTION BY MUNICIPAL AUTHORITIES.

THE passage of a bill [Assembly Bill, No. 778,] in the New York State Legislature creating a Bureau of Fire-Alarm, Telegraph and Electric Appliances for the city of New York deserves more than passing notice. The scope of this bill will be best understood by the following abstract relating to the powers and duties of those in charge of the Bureau:

> Said Bureau shall have charge of the construction, care and management of the fire-alarm and telegraph system of said department. Said Bureau is also charged with the duty of enforcing all the provisions of this title, and all rules, regulations, orders and requirements made thereunder. In regard to electrical wires or currents for furnishing light, heat or power for any building in this city, and in regard to the arrangements and use of said light, heat and power, the Board of Fire Commissioners is hereby authorized, and required, to make rules and regulations in regard to electric wires and appliances and currents for furnishing light, heat or power, which may be introduced into or placed in any building in the said city. * * * Before any such wires, currents or appliances are used or operated for any purpose, such compliance shall be duly certified, in writing, by the superintendent of fire-alarm, telegraph and electrical appliances.

Any violation of this law is punishable with a fine of $50, and if the violation be continued a penalty of $250 is imposed.

The legislation embodied in this bill is the first, in this country, which has imposed upon a municipal bureau the obligation of inspecting and passing upon the interior wiring of buildings. Up to the present time such inspection and approval has been left to the various boards of fire underwriters throughout the country, and the inauguration of this new order of things, in this city at least, may bring about a state of affairs requiring the serious attention of all engaged in electric lighting and the distribution of electric energy generally. The rules which the new bureau is called upon to frame will evidently have to be fashioned much after those already in vogue among the fire underwriters, and with few modifications such will serve excellently. It is evident, however, that the Board of Fire Underwriters will maintain their own inspections unless they are thoroughly satisfied that the work of the municipal bureau is of such a character as to be beyond reproach. In any event, the person placed in charge by the municipal bureau ought to possess the highest ability and integrity, and enjoy the confidence, not only of his own chief, but of the Board of Fire Underwriters as well. Without a cordial understanding between these two bodies, much confusion and not little hardship is bound to follow upon the inauguration of the city electrical bureau of inspection. It is greatly to be desired that the selection of the proper official be made with this object in view and "party politics" be completely put aside. As it is more than likely that the course pursued in New York will be followed in other cities, it is doubly desirable to have this matter successfully inaugurated. Properly conducted, such a bureau ought to be of the greatest benefit, but in incompetent hands it would be a curse to the industry.

Another point to be determined is the scope of the duties of the bureau. We have always been under the impression that the Board of Electrical Control, which has just renewed its lease of office for another year, has claimed and exercised some sort of supervision over central station plants and circuits.

A FAILURE WITH A LESSON IN IT.

THROUGH excess of zeal accompanied by lack of discretion, a hunter once upon a time found himself in the position of having an exceedingly lively tiger by the tail, and was thereupon confronted with the awful conundrum, as to whether he would do worse to hold on or to let go. This appears to be substantially the situation which now confronts the London Electric Supply Corporation, organized four years ago to produce and distribute electricity on a colossal scale, as if, like the brewing and sale of beer, it was simply a question of a sufficiency of working capital. Placing themselves unreservedly in the hands of a single adviser—a young man possessing a degree of ability which cannot be questioned, but without that experience which tends to sober the judgment and to chasten undue self-confidence, and who was forthwith installed in the diverse, not to say conflicting positions, of engineer, inventor, patentee and contractor—the shareholders launched forth into one of the most colossal undertakings of the century, regardless alike of the teachings of experience and of the predictions of conservative electrical engineers. As the chairman at the recent annual meeting of the company expressed it, "The board had relied on the scientists, who had been clever enough to satisfy some very hard-headed men of business to adopt their views and to find money to carry them out." The scheme thus attempted to be carried out is familiar to most of our readers, and need not be described in detail. Two gigantic dynamos, having armatures 45 feet in diameter, driven by 10,000 h. p. engines, were to transmit current at a pressure of 10,000 volts, several miles into the heart of London, to supply over 2,000,000 16 candle incandescent lamps. On this extraordinary undertaking nearly $4,000,000 has thus far been expended, and although the company began to supply current over three years ago, the output to-day has reached only 36,000 lamps. The results of operations of the past year show receipts in round numbers of $77,000, and expenses of $112,000, a net deficit of $35,000. By way of comment, on this exhibit, as the Irish judge said, "The only thing requisite is silence, and as little of that as possible." One cannot however but admire the true Anglo-Saxon pluck with which the shareholders of this ill-starred undertaking have stood by their colors, and still stand by them, inasmuch as they now propose to mortgage the plant for $250,000 more, and as one director remarked, "try the experiment to the bitter end." Having abandoned the enormous dynamos referred to which are still incomplete, it is proposed to enlarge the plant as soon as possible to 90,000 lamps, using the 1,250 h. p. dynamos now in service. One cannot but hope that the undertaking may be attended with at least a reasonable degree of success. Such splendid courage deserves a happier issue than has so far attended the venture.

WHO DID THIS?

THE Legislature and Governor who passed and approved the recent bill for setting up a trotting-course in Central Park (just now repealed in reluctant obedience to the indignant demand of the people of this city) may attempt almost any imaginable enormity of legislation. Scarcely anything thus far attempted has been worse than the act "To authorize the East River Gas Company of Long Island City to supply gas and electricity in the city of New York," introduced by Assemblyman Byrne March 15, and which has been passed by both houses of the Legislature and now awaits the action of the amiable but plastic gentleman who sits in the Governor's chair.

Below is the first section of the bill:

> SEC. 1. The East River Gas Company of Long Island City shall have the right, and it is hereby empowered, to supply gas and electricity in the city of New York, and for that purpose is hereby authorized, without other or further authority of law or ordinance, to lay and maintain requisite conductors, mains and pipes through and under any streets, avenues or public places of such city. For the purpose aforesaid such corporation shall have the right, and it is hereby empowered, to lay and maintain such conductors, mains and pipes under and across the East River and across any intervening land belonging to the city of New York, or to private persons, at such places as it may determine: Provided, however, that such conductors, mains or pipes shall be so laid and maintained as not to obstruct or impair navigation, commerce or anchorage of any navigable waters without the consent of the Secretary of War. And such corporation shall have the right, and it is hereby empowered, to acquire by condemnation or purchase such real property, public or private, or right, interest or easement therein, for the laying and maintaining of its mains, pipes and conductors, as may be necessary in the exercise of the powers hereby conferred. Such property when so acquired, shall be deemed to have been acquired and held as and for a public use.

The remaining sections provide for the condemnation of property and authorize the leasing by the Long Island Gas Co. of other companies or properties; thus preparing the way to the formation of a huge monopoly.

The reputation of Long Island City is somewhat unsavory in the nostrils of most people within some miles of it. It is both physically and politically malodorous. There is a distinct effluvium of spoils in the scheme under notice. But we take leave to doubt whether so considerable and comprehensive a plan for plundering the city of New York generally, and existing electric lighting companies in particular, was concocted on the borders of Newtown Creek. "The voice is the voice of Jacob but the hand is the hand of Esau." Tammany, directly or indirectly, is more than likely to be the instigator and participant of the business.

It is quite unnecessary to point out in detail the menace to the public, to the existing subway company and to electric lighting companies now serving public and private consumers.

LIGHTING THE WORLD'S FAIR.

THE course of events in regard to the award of contracts for lighting the World's Fair, as well as for the power plant, has been somewhat extraordinary, and on the whole the situation is one to be regretted. In the first place, the management of the Fair appear to have had little idea as to the cost of electrical plant, and hence were talking about thousands of horse power and hundreds of thousands of lamps in a way that was utterly absurd. But when it came to bidding on the smaller figures dictated by prudent advisers of the management, another development not less strange was seen. The price for the use and maintenance of 5,000 or 6,000 arc lamps was cut from $38.50 down to $20 per lamp, and now the price of incandescents has been cut from $18.50 to $5.95. This latter reduction on a total of 93,044 lamps, makes a saving of $1,200,000 out of a proposed $1,720,000, to which might be added a saving of about $100,000 on the arc lighting!

We note some very vigorous comments in the Chicago newspapers on these figures, and must admit that a most unfortunate showing has been made. Such an enormous reduction can only be interpreted by the public to mean either that a tremendous profit was sought for in the first instance or else that the work has now been taken at a terrible loss to keep out competitors. Both aspects of the case give a bad impression.

The same criticism is more or less pertinent as to the power plant, where, it is said, equally inflated estimates were in contemplation. As we understand it, a large part of the contract for use of generators, etc., has been allotted at $2.50, a figure far below what was asked by some parties. It is absolutely certain that the company taking the work at $2.50 per horse power can make no profit. Probably all that it hopes for, or wanted, is a return in the advertising it will secure, and such a return no one can grudge it.

It seems to us a very great pity that at the outset the Fair management were led to believe that electric light and power cost nothing, or that even if they did involve expense they would be furnished on a "free lunch" basis.

Mutual Action of Vacuum Discharge Streamers.

WE print elsewhere the research undertaken by Dr. M. I. Pupin on the action of vacuum discharge streamers upon each other. It is worthy of attentive study on account of the light which it may throw on the actions that determine the formation of the solar corona. The effects obtained resemble in many respects, though on a small scale, the repulsive actions which some authorities ascribe to the streamers in the sun's corona; but Dr. Pupin does not accept without reserve the explanation, hitherto given, of the repulsion as due to electrostatic action.

THE WOOD INCANDESCENT DYNAMO.

One of the first to enter the field of arc lighting was Mr. James J. Wood whose arc machine still maintains a prominent position among the successful arc dynamos, and who has succeeded in operating more lamps from one machine than have been attained probably by any other designer.

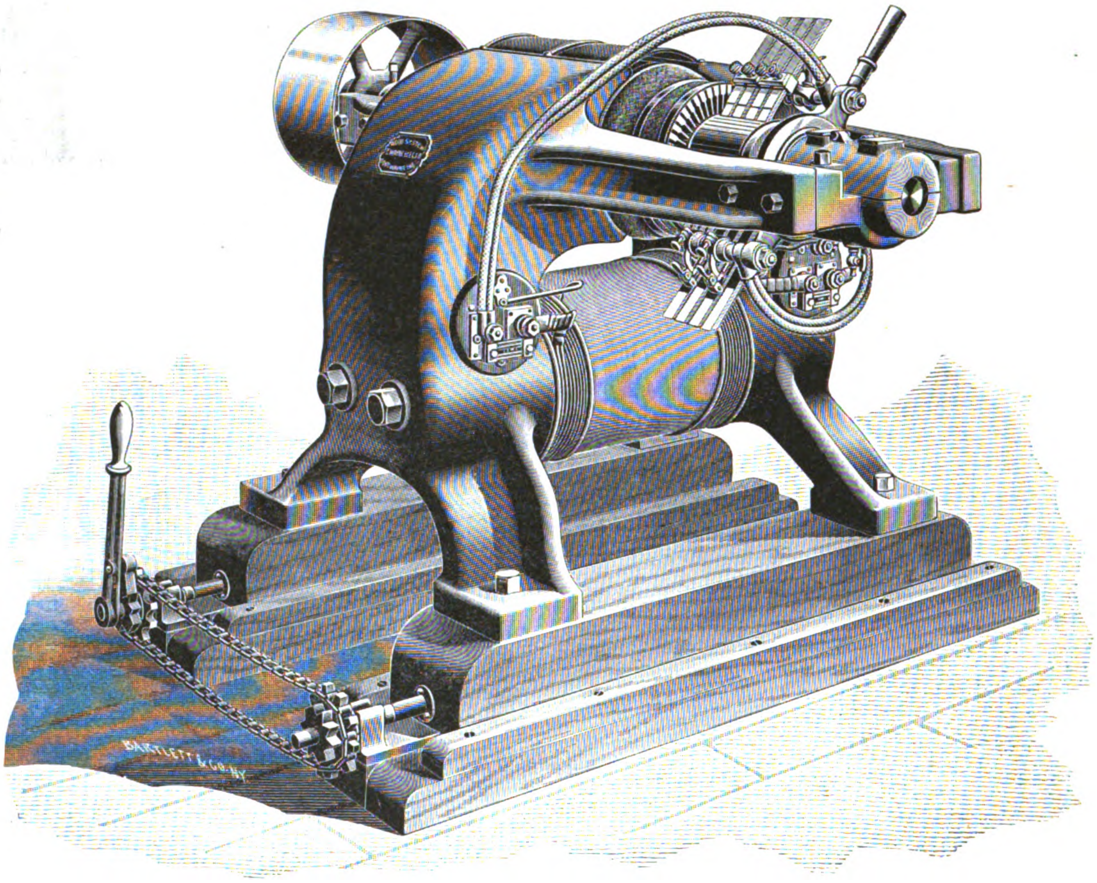
More recently Mr. Wood has devoted his attention to the designing of an incandescent machine, which is built by the Fort Wayne Electric Company, and is illustrated in the accompanying engraving. The magnetic frame involves but a single circuit with only two joints, the exciting coils being wound on a wrought-iron core. The machine is compound wound for constant potential and regulates perfectly at all loads with a high efficiency.

The weight of the Wood dynamo for its output is exceedingly low, as will be evident from the following data which refers to a 500-light machine :

Weight of wire on armature	58	pounds.
" " field	133	"
Total weight of machine	3,600	"

This gives a weight of only 191 pounds of copper for a machine having a capacity of over 30,000 watts, and a weight of only .12 pound total per watt of output.

The machine is provided with self-contained multiple fuses for each end of the circuit and also with an equalizing connection. The latter is intended for connecting several machines in multiple, and is so placed in the circuit that one machine will tend to equalize the potential of its neighbors; or, in other words, keep all the machines working at the same potential, independent of the load. In order to facilitate the running of the machine it is mounted on a patent anti-friction, insulating and sliding base, which is so arranged that the motion is positive in either direction whether the belt be tightened or slackened. The workmanship of the machine throughout is of the usual excellence found in the machines designed by Mr. Wood, all parts being made to gauge and interchangeable.



The Wood Incandescent Dynamo.

VARYING PROPERTIES OF OIL AS AN INSULATOR.

The experiments on high-tension discharges of high frequencies described in The Electrical Engineer, by Prof. Elihu Thomson, besides illustrating the simple methods required to obtain brilliant discharge effects seemed to point to some remarkable properties of oil as an insulator, and Professor Thomson has referred to the great future which the application of oil insulation opened up in the field of high-tension transmission. Continued experiment, however, has developed facts which have led Prof. Thomson to modify his views somewhat on the subject of oil insulation, and in reply to a letter on this subject he writes us as follows :

"It is more than probable that I shall have to make a revision of my views as stated in relation to oil as an insulator. In conducting my experiments I have been testing the striking distance in oil with varying periodicities and with varying forms of discharge electrodes, and I find that the results would seem to indicate that with an oil such as we have been using for the insulation of the high-period discharges at enormously high voltages, there is a much less resistance to discharges of the ordinary alternating character at low rates, such as 125 periods, or 250 alternations.

"I find that considerable distances in oil are punctured. In fact, the distances in some cases are quite comparable with the distance which the discharge leaps in air. I find, also, that with high-period currents, such as I get from my high-period alternating machine giving from 3,000 to 5,000 or more alternations per second, different effects are obtained; though the experiments are not yet complete.

"One of the most curious things noticed in the conduct of the experiments has been the time which it takes to break down the oil. For example, for a short contact of a half second or so, oil even in fairly thin layers seems to insulate, but if the contact be continued over some seconds, or even to half a minute or more, the discharge may break through the insulating layer. The time taken seems to increase with the distance of the electrodes apart under the oil. I have given these preliminary results hoping to investigate the subject pretty thoroughly and to really understand something about oil as an insulator before we get through."

ON THE ACTION OF VACUUM DISCHARGE STREAMERS UPON EACH OTHER.[1]

BY M. I. PUPIN, PH. D., COLUMBIA COLLEGE.

VARIOUS phenomena which I observed in the course of an investigation on the coronal effects produced by electrical discharges through rarefied gases, led me to the belief that under certain conditions two electric current filaments in a rarefied gas may act upon each other oppositely to the direction of their mutual electro-dynamic action, and that this additional action may sometimes be far predominant over the electro-dynamic action; that is to say, we have a strong repulsion where electro-dynamic action would produce an attraction. A brief account of these investigations was given on Feb. 8, before the Astronomical Section of the New York Academy of Sciences. The following paper is limited to the description of the experiments by means of which the existence of the above-mentioned action was definitely proved.

Fig. 1 represents the apparatus first employed. Four glass bulbs, A, B, C, D, each having a capacity of about a litre, are connected by four glass tubes of small bore to a glass reservoir E. A stop-cock F serves to connect the apparatus to a mercury pump. The reservoir has a diameter of 10 cm. and a length of 22 cm. The mouths *e*, *f*, *g*, *h*, of the four narrow-bore tubes form a square whose side is 10 cm. long. The bulbs are covered with tinfoil and the tinfoil is then well coated with paraffine. Each tinfoil covering has a well-insulated copper wire attached to it.

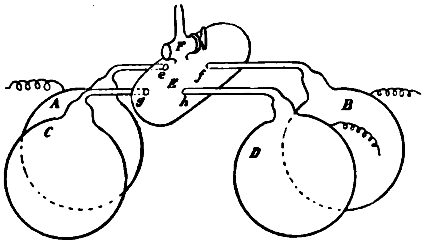


FIG. 1.

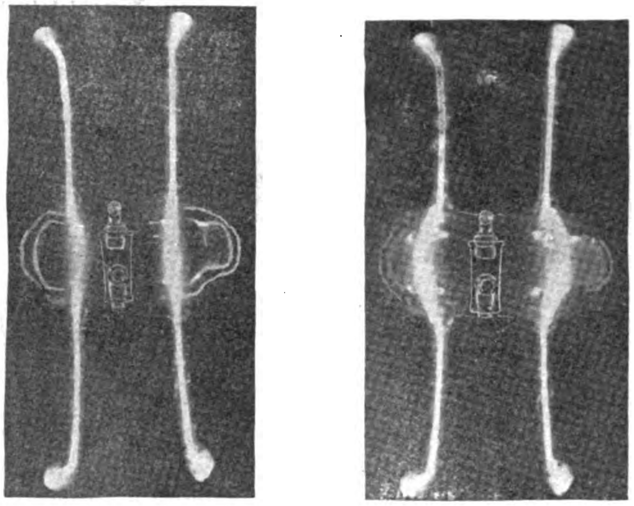
After producing a 2 mm. vacuum in the apparatus the bulbs A and B were connected to the secondary poles of a small Ritchie induction coil, whose primary was fed by an alternating current of 125 periods per second. The electromotive force in the secondary coil was varied by varying the current in the primary; this was done by means of a resistance box in the primary circuit. The electric flow between the bulbs is, of course, due to the condenser effect between the tinfoils and the vacuum.

At the pressure of 2 mm. the discharge was easy, steady and very diffuse along its path through the reservoir. Disconnecting AB and connecting CD to the induction coil the discharge was the same in character as before. Connecting both pairs of bulbs in parallel to the induction coil, that is, the bulbs A and C to one pole and B and D to the other pole, the two discharges, going on simultaneously, were the same in character as before, except that they were somewhat convex towards each other.

The pressure was then increased by turning the stop-cock once around and allowing some air to get in. The discharges were less diffuse but more luminous, and less convex toward each other. With the increase of pressure the discharges became less and less diffuse and their convexity towards each other diminished until, when a certain gas pressure was reached, it disappeared. At this point the discharges were very little diffuse and when allowed to pass through the reservoir simultaneously they remained rectilinear, but somewhat unsteady, oscillating quite appreciably about their rectilinear paths through the reservoir, but the oscillations were always in the plane common to their rectilinear paths.

The pressure was still increased by turning the stop-cock once around and allowing some more air to get in. The discharges became still less diffuse along their path through the reservoir and when allowed to pass one at a time they were quite steady and rectilinear. Both being allowed to pass through the reservoir simultaneously they were appreciably concave toward each other, but the concave arcs were in the plane passing through their shortest path in the reservoir. There was evidently a repulsive force acting between the discharges. This repulsive force increased continually with the increase of pressure in the vacuum, but with the increase of the force the steadiness of the discharges along their paths through the reservoir when they were both passing simultaneously gradually diminished. Fig. 3 is a photograph of the discharges when taking place simultaneously in a vacuum in which the repulsive force just described was moderate. Fig 2 is a photograph of the same discharges, but when taking place one at a time. Fig. 2 indicates that there is a repulsion between the discharge and the nearest wall of the reservoir, but this repulsion is very small in comparison to the repulsion acting between the streamers, when they take place simultaneously, as Fig. 3 indicates. The photographs were taken by very short (1 to 1½ second) exposure, so strong is the luminosity of these discharges. They were taken when the repulsion was moderate, because when the repulsion is very strong the discharges oscillate very rapidly, so that they could not be well photographed with the apparatus employed. When the repulsion was so strong as to cause the streamers to curve way out and from time to time strike the nearest wall of the reservoir, the vibrations became very violent every time the streamers struck against the walls. They rebounded against the walls just as if they were luminous vibrating strings.



FIGS. 2 AND 3.

At this pressure in the vacuum it was very difficult to start the discharge and I had to strain the alternating machine and the induction coil to their utmost to make the start.[1] But when once started the discharge continues without any interruption even if the potential at the tinfoils is lowered 15 to 20 per cent.

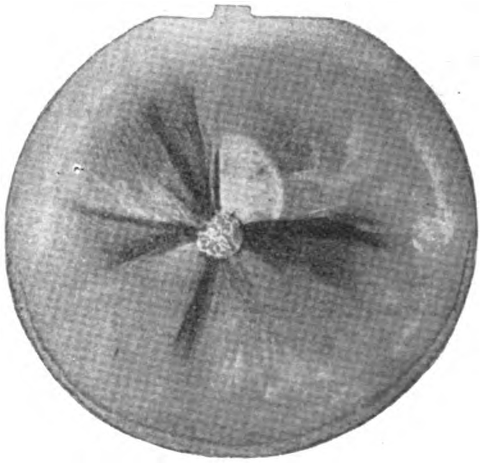


FIG. 4.

---

[1] From the *American Journal of Science*, Vol. XLIII, April, 1892.

[1] A gentle touch of the apparatus with a conductor will sometimes start the discharge at once when all other means of making this start fail.

The rate at which the temperature of these discharges increased with the increase of pressure in the vacuum seems to be much more rapid than the increase of the pressure; (the impressed E. M. F., of course has to be increased with the pressure) and with the increase of the temperature the luminosity of the discharge increased also. With the increase of luminosity the color of the discharge changed from the pink color, which is the characteristic color of the ordinary Geissler tube discharges through rarefied air, to a color which inclined more and more toward the white. With the increase of the pressure the diffuseness of the discharge disappeared, but instead of the diffuse pink color there appeared a beautiful green phosphorescent light which filled the whole reservoir. This phosphorescent light is so strong, that even an almost instantaneous exposure is sufficient to give it time to act upon the sensitive plate, as appears from the photographs in Figs. 2 and 3. At some future date I shall describe experiments which seem to be a strong proof that phosphorescence produced by electrical discharges depends on the temperature and only in so far on quantity of the discharge and on the vacuum, as the temperature of the discharge depends on them. The investigations of Crookes, Goldstein, and others lead to the conclusion that a high vacuum with its cathode rays is most favorable if not indispensable to the development of strong phosphorescence. In my experiments a good vacuum (of about 2mm.) gave no phosphorescence whatever, whereas a poor vacuum (even with as high a pressure as 100 mm.) gave very strong phosphorescence, and that, too, not only in places where the discharge struck the walls of the vessel, but also in places which were far away from the discharge. Presently I shall describe an experiment which shows that the gas as well as the glass becomes strongly phosphorescent. My observations cannot, therefore, be well reconciled to those of Crookes, Goldstein, etc., unless the cathode rays be supposed to be very thin and very hot discharge filaments. I have several experimental facts which speak in favor of this hypothesis, but a discussion of them would lead me beyond the limits of this paper.

I find that some astrophysicists assume the existence of a repulsive force acting between the streamers of the solar corona; it was the peculiar behavior of the corona-like vacuum discharges which, in addition to other phenomena that came under my observation, forced me to assume that repulsive forces must be active between the filaments of these discharges, although at that time I was perfectly ignorant of the details of the various electrical theories of the solar corona. The streamers of these discharges are very unsteady and very much split up when the vacuum is poor. A photograph of a discharge of this kind is given, Fig. 4.[1] As the vacuum improves, the corona-like discharges become a great deal steadier, less torn up and quite diffuse, but never uniformly distributed over the whole spherical electrode. Fig. 5 represents the photograph of a discharge in the vacuum of about 20 mm. pressure. These photographs belong to my collection of photographs of corona-like vacuum discharges, an account of which I expect to give at some future time.

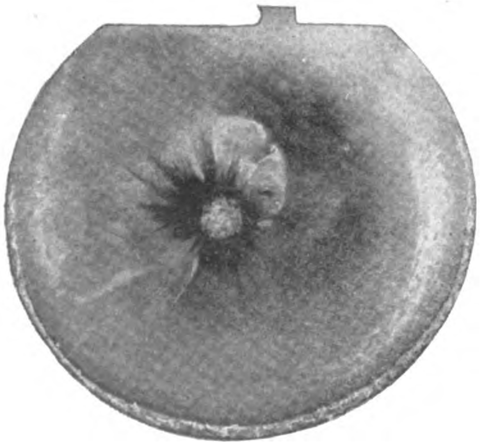

FIG. 5.

The question arose then, naturally, what is the cause of this repulsion? Electrostatic action suggested itself first, of course. But various observations which I made during my investigations on vacuum discharges made me favor another view, the view, namely, that the repulsive force between vacuum discharge streamers is due to a strain in the vacuum produced by the peculiar distribution of the gas pressure resulting from the peculiar distribution of temperature. If this view is correct then there should be no action between two vacuum streamers passing in two separated vacua. This suggested the following experiment:

Investigate the action of two discharge streamers upon each other when two separate discharge reservoirs are employed. Fig. 6 represents the apparatus (with its dimensions in cm. marked), containing one of the reservoirs, two of which were placed side by side in the experiment. The bore of the capillary tubes *e*, *c*, *d*, *f*, was about 1.5 mm. The bulbs AB were coated with tinfoil, and the whole arrangement was the same as in the experiments with the apparatus given in Fig. 1. The two apparatuses communicated with each other by means of a stop-cock, so that the pressure was the same in each. The discharge in one apparatus did not influence the discharge in the other, no matter what the pressure was, up to the limit at which I could still obtain a discharge; which was about 60 mm. From this I conclude that the repulsion which I observed in the previous experiments was probably not due to electrostatic action. The probability of the correctness of the other view is therefore considerably strengthened.

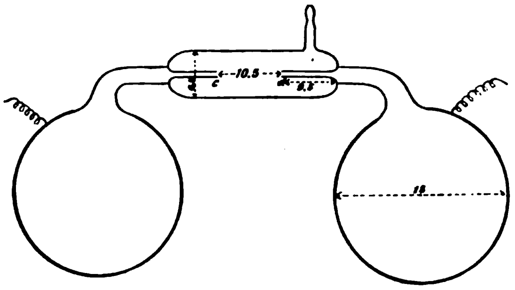

FIG. 6.

The apparatus for this experiment was constructed with two other objects in view, which ought to be mentioned here.

1st. To locate the phosphorescence. In this I was quite successful. It surrounded the hottest parts of the discharge, and therefore it was most intense in the narrow parts of the apparatus. Within the reservoir it extended from *c* to *d* in form of something like an ellipsoid of revolution, with the extremities of its longest axis at *c* and *d*, and at times this ellipsoid did not fill out the reservoir at all, which proves that the phosphorescent light in this part of the apparatus is due to the phosphorescence of the rarefied air and not to the phosphorescence of the glass, although in the narrower parts of the apparatus where the hot discharge was very near the glass the glass was also phosphorescent.

2d. To study what I call the ramification of the discharge. As soon as the pressure reached a certain limit, the luminosity in the bulbs (which at low pressures was more or less uniformly diffused throughout the bulbs) become streaked, and at still higher pressures the whole discharge in its path through the bulbs divided itself into a number of distinct streamers, the number of streamers diminishing with the increase of pressure; given pressures produced invariably the same number of streamers. In this experiment I did not succeed in reducing the number of these streamers to less than two. The streamers rotated more or less uniformly in one direction or the other. The angular velocity of rotation seemed to increase considerably with the current of the discharge.

An exhausted glass bulb without electrodes when brought into the vicinity of these discharges emits a faint yellowish light which looks very much like the light of some forms of the aurora borealis. The bulb seems to remain perfectly cool. Lack of time and facilities have prevented me from determining the spectrum of this cold glow.

My thanks are due to Professors W. P. Trowbridge and J. K. Rees for the interest which they took in my work; also to Mr. Mann, of the Astronomical Observatory, for the very valuable service which he rendered to me in photographing these discharges. I hope to continue this work with improved facilities as soon as time will permit.

Columbia College, February, 1892, Department of Electrical Engineering.

ELECTRICAL METHODS OF ANALYSIS.[1]

ELECTROLYTICAL methods of analysis have long been in use for certain restricted purposes by the generality of chemists, and have been adopted as a kind of cult by a few enthusiasts in Germany and America, but until quite lately electrical methods pure and simple have been almost unknown. We recorded an attempt of the kind a short time ago which was based on the alteration in conductivity of milk caused by the addition of water, and pointed out that the analyst using this process would be dependent upon the courtesy of the milk dealer to inform him of the source whence the water was derived and to provide a sample for examination. A more feasible plan, resting on the same principle, is now suggested for determining the extent to which glass is attacked by water. According to popular belief glass is entirely unaffected by "chemicals" of all kinds, and still less is water supposed to have any action upon it. So far from this being true, it is very appreciably acted upon by the most diverse solutions, and notably by water itself, and it is frequently a matter of importance to determine the degree of vigor of this action, and to discover which composition is best suited for a glass intended to resist it as far as possible. It was found that the increase of conductivity of water contained in a glass vessel was in direct proportion to the corrosion of the glass, and the net results of the experiments served to confirm the observation previously made by other methods that the extent to which the glass was attacked increased with the temperature, and was greater with a new vessel than with one that had been used before. That the method is accurate appears probable from the fact that the deductions drawn by its means agree with those obtained by the very delicate process of titration devised by Mylius and Forster. The method of determining the chemical compositions of solutions by the observation of their physical properties has already done good service, and has led to the devising of such instruments as the refractometer and the polarimeter, and the time may yet come when the resistance box and the Wheatstone bridge may equally be of specific if not of general utility.

DEWEY'S INDUCTION ELECTRIC RAILWAY SYSTEM.

There is no evidence that existing methods of street railway practice will be abandoned, especially those employing the overhead construction, as it will always have a place on account of its simplicity even after the most revolutionary invention appears. But it has its disadvantages when used upon the principal streets of cities and towns. The question, then, is: What kind of an electric system is waited for and required for cities and what will be its advantages. One answer would seem to be: First, a system that will receive its power directly from a power station without the use of exposed or bare line conductors; second, a system without a slotted conduit; third, a system that will allow a high voltage to be used without danger; fourth, a system that will not require batteries on the cars.

An electric system claimed to have the desired advantages has been devised by Mr. M. W. Dewey, of Syracuse, N. Y., and will now be briefly but clearly described. The principle upon which this system is founded is that of induction, that is, the current used on the car to propel it can be induced by, and be entirely separate from the current generated at the power station and transmitted along the line of travel by the line conductor. In applying this method of induction, use is made of the fact that the presence of a complete or nearly complete magnetic circuit in or around the primary and secondary electric circuits greatly increases the inductive effects of the primary current. The means by which this method may be carried out consist in constructing the elements of a magnetic circuit or each of a number of such circuits in two parts, one of which is stationary, and embedded in the roadway, the other being carried by the car, Fig. 1. The stationary part is energized by a pulsatory or alternating current and the induced current is generated in one or more coils surrounding the movable part of the magnetic circuit. The movable part of the transformer on the car is continually in inductive relation to one or more of the stationary parts of the transformer.

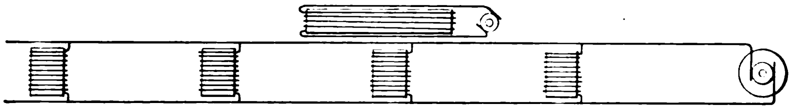

Fig. 1.

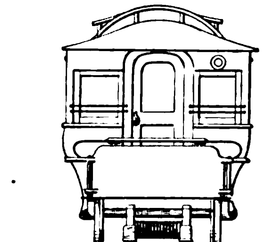

Fig. 3.

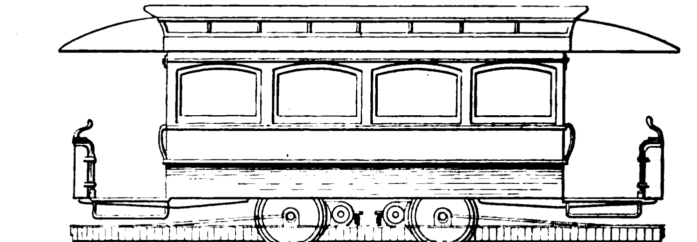

Fig. 2.

Figs. 1, 2 and 3.—Dewey's Induction Railway System.

The plan is to place coils upon U-shaped iron cores about the length of a car apart, in the roadbed between the rails, the ends of the core on a level with the pavement or slightly above it, and protected by roughened iron wearing plates, Figs. 2 and 3. The conductor extending to the coils is laid underground along the railway. The several cores and coils in the roadbed form one-half of the transformer apparatus, the other half of which is carried on the cars. Each motor has an inverted iron core upon which the secondary coils are wound. The ends of the vehicle core come above, and in proximity to, the ends of the roadbed cores. If a complete magnetic circuit is to be maintained by the cores, the vehicle core is made somewhat longer than the distances between the roadbed cores, and iron brushes or wheels are secured to the ends of the vehicle core to make contact with the stationary cores.

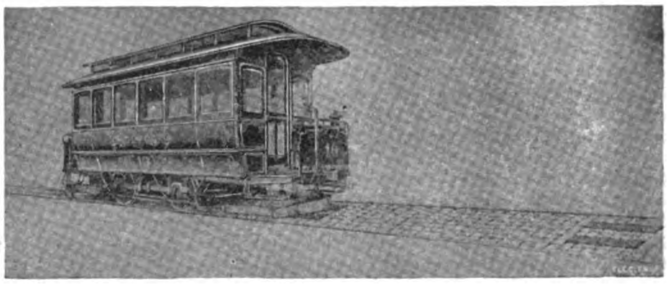

Fig. 4.—Dewey's Induction Railway System.

The first cost of construction of this system would be somewhat greater than that of the overhead, but is claimed by the inventor to be much less than a cable or slotted conduit road, and far less expensive to keep in working order. The entire road need not be equipped with this system unless desired, but only the part passing through the principal streets, the rest being equipped with the overhead construction which can be made to work well and in harmony with the proposed system, of which the accompanying illustration Fig. 4 will insure a clear understanding.

ALUMINUM LIGHT.

Finely divided aluminum has previously been suggested as a substitute for magnesium as an actinic light for photographic purposes. Now that it is cheaper than magnesium, the following formula for a mixture, which is recommended by a French contemporary as giving a powerful flash, may be of use to those interested in photography—100 parts aluminum powder, 25 parts lycopodium, 5 parts ammonium nitrate. This powder can be used for flashing in an ordinary spirit lamp, but gives a brighter and more powerful light if the powder be flashed into the flame by means of a jet of oxygen gas.

The Cleveland, Ohio, Electric Club is in a thriving condition. It meets on the first and third Wednesdays of each month, and has already fifty members.

CARBON ACCUMULATORS.

BY

Jas. A. Lounsbury.

In an article published in a recent number of The Electrical Engineer, Prof. W. M. Stines gives the results of some experiments with accumulators having carbon electrodes, in which the secondary current was produced by the reunion of oxygen and hydrogen gases previously formed by the decomposition of water. A few words in this connection regarding some facts which came under the writer's notice about three years ago, may be of interest. The experiments were not very complete and the data obtained is of little value except in a general way, as facilities for making accurate measurements were lacking.

While using, in the regulating circuit of an arc dynamo, a resistance composed of two arc lamp carbons immersed in a weak solution of sulphuric acid, the writer found that the positive electrode was badly corroded after a current of about five amperes had been passed through the solution for a short time, and that the negative carbon had increased in size. This increase however, was not equal to the decrease in size of the positive electrode, for a considerable amount of carbon remained in suspension in the liquid.

Thinking that where there was an action of this character, a reaction might be looked for, and the wires from the dynamo were disconnected and the carbons connected together through a galvanometer. A large deflection of the needle resulted. Afterward a large cell was made with plates composed of a number of lamp carbons, this being the only form of carbon available at the time. In this battery the total area of the plates was about 400 square inches. After charging with a current of twelve amperes for about an hour, the cell was short-circuited through an amperemeter, and a secondary current of about nine amperes was obtained. This rate of discharge was maintained only for a few minutes, however, the current gradually dropping to about four amperes, where it remained fairly constant for a while, and then dropped slowly to zero. As a low reading voltmeter was not at hand, no tests to ascertain the voltage developed were made. It is probable that the gas generated by a charge of twelve amperes for an hour, was considerably in excess of the storage capacity of the plates, and that as large an output would have been obtained with a smaller charge.

In the first cell carbon was transferred from the positive to the negative electrode, but in the larger cell this deposition of carbon was not noticeable, though the positive plates showed signs of corrosion, and considerable carbon remained in suspension in the liquid, as before. The reason that this transfer of carbon was not as noticeable in the second case, was probably due to the fact that while the charging current was doubled, the surface area of the plates had been increased about 30 times. It is probable that for a given area of electrode surface, the amount of carbon deposited would increase, and the amount held in suspension decrease with the *rate* of charge. The same instability of charge mentioned by Prof. Stines was noted; a full charge disappearing completely in ten or twelve hours with battery on open circuit. This was supposed to be owing to the escape of the gases into the air. This escape of gas might have been prevented in a large degree, by the use of an electrolyte in the nature of a paste. One peculiar feature noticed was that after short-circuiting the battery until the voltage had fallen to about one-half the original, if the short-circuit was broken and the cell allowed to stand for a short time, it would regain its original strength, acting in this respect similar to an over worked primary battery.

This subject of carbon secondary batteries is a fascinating one, and could they be made practicable, the storage battery would again return to the high position in the regard of the public which it has occupied periodically for the past eight years. Accumulators of this kind would be very cheap to manufacture and maintain. The absence of all active material, so called, would be a great advance over the present method of manufacture. The efficiency is very good, though it is doubtful if the *weight* efficiency is much higher than that of the lead type.

Prof. Stines' form of cell has the great advantage over that employed by the writer in that he obtained a very large storage capacity for the gases by the use of finely divided carbon, with a great reduction in bulk. The reversibility of a carbon accumulator would be a great point in its favor. In charging, the negative plate which had "grown" could be made the positive, and so become the one subject to disintegration and the plate, positive in the previous charge, and therefore corroded, would be built up. It is probable that the number of times this reversal could be made would be limited, as the amount of carbon taken from the positive plate each time would not be deposited on the negative, a portion being added to that already in suspension in the liquid.

THE FIVE-WIRE ELECTRIC LIGHT STATION AT TRIENT, AUSTRIA.

As most of the electric light stations in the United States which are operated by water-power are so planned that the generators are located near the water-power, the following abstract of a recent lecture before the Austrian Society of Engineers and Architects, by Herr Hugo Koestler, will prove interesting, as it describes a plant in which the dynamo station is located near the town and the water is carried to it under considerable pressure for quite a long distance from the dam. The town of Trient, in Southern Tyrol, population about 23,000, has always been subjected to more or less danger from a neighboring stream, which threatened during high water to flood the adjoining land. Several dams were built from time to time to regulate this stream and finally, in 1884, the municipal authorities built a dam about a mile away from the town, which afforded a fine water-power.

This power they determined to use for generating electricity, but instead of locating their station at this point, where a fall of some 170 feet was available, they constructed a canal, principally in tunnel, 0.47 mile long, 3.28 feet wide and 2.95 feet high. Unfortunately the speaker did not state how this tunnel was driven, which was a serious omission, since the cross-section is so small that the engineering details of the work would be interesting. This canal empties into a reservoir, containing about 90,000 gallons, which serves as a regulator to maintain a fairly uniform pressure at the turbines, about 2,000 feet distant and 289 feet lower. The reservoir and turbines are connected by two cast-iron mains 25.6 inches in diameter, uniting at the power station into a single main 35.43 inches in diameter.

The generating station is about 3,400 feet from the centre of the town and contains 6 Girard turbines; each furnishing 140 actual horse power at 265 revolutions. Six direct-coupled dynamos are used, each giving 160 amperes at 550 volts, so that the station has a maximum capacity of 960 amperes. The distributing system is arranged on the five-wire plan, and is underground except in the outskirts of the town. The "outer" conductors have a difference of potential of 440 volts, which is divided by the three "inner" conductors into fields of 110 volts each. Two arc lights are used in one field or group, four on alternate conductors or eight when the outside wires are connected. The incandescent lamps are wired in small groups with an E. M. F. of 110 volts, while the connections of the electric motors are made to give 110, 330 or 440 volts as desired.

A secondary battery has been set up in the generating station and is charged during the hours of highest consumption. Its capacity is such that in case of accident to the water mains or driving machinery, it could supply nearly the maximum current required for public and private purposes for about an hour. The plant was designed by Chief Engineer Appollonio and his assistant, Herr Foyorelli, the latter being in charge of the station at present. The turbines were furnished by the Machinery Works at Vevey, Switzerland, and the electrical apparatus by the Vienna branch of Siemens & Halske.

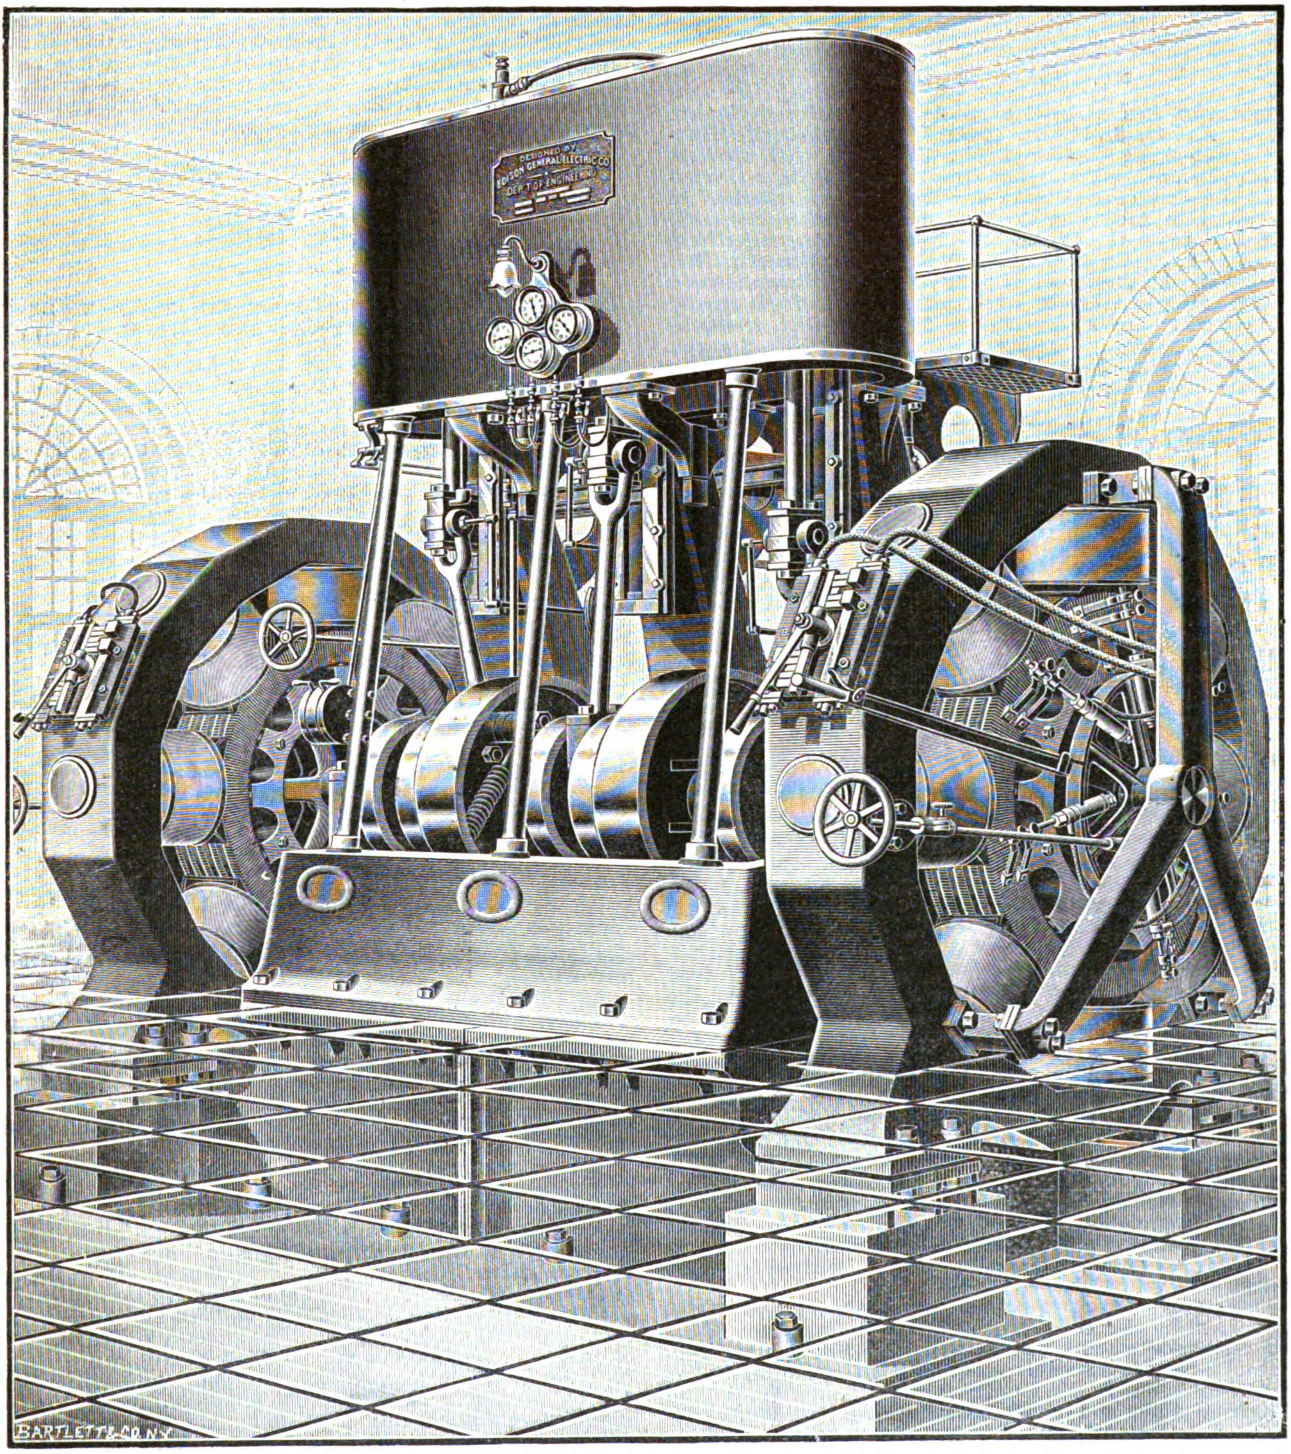
The entire plant, including land damages, canal, mains, buildings, turbines, electrical apparatus, wiring and lamps, but exclusive of the dam, which was not built for power purposes originally, cost about $233,400. The public lights supplied from the station embrace 560 incandescent lamps of from 16 to 35 c. p. and 28 9 ampere arc lamps. The private consumers had about 6,000 incandescent and 30 arc lamps in use at the beginning of the current year, and also took something over 200 h. p. for motors of from $\frac{1}{16}$ to 50 effective horse power.

NOTE ON ROTARY CURRENTS.

At a recent meeting of the London Physical Society, says our London correspondent, a note was presented on the above subject. Alternate currents could be obtained from an ordinary direct-current dynamo by making contact with two points in the armature, say by connecting these points to insulated rings on the shafts, and using extra brushes. A direct-current motor, similarly treated, transforms direct currents into alternating currents, or into mechanical power. If two pairs of points in the armature be selected, situated at opposite ends of two perpendicular diameters, then two alternating currents, differing in phase by 90 degrees can be obtained; and by choosing suitable points in the armature, two, three or more currents differing in phase by any desired angles can be produced. In ordinary motors the connections for doing this would be troublesome, but the Ayrton and Perry form, which has a stationary armature, lends itself readily to this purpose, for contact can be made with any part of the armature with great facility. A motor of this kind was exhibited, in which contact was made with four equidistant points on the armature. On connecting opposite points through fine platinum wires, and running the motor slowly, the wires glowed alternately, one being bright, while the other was dark, and *vice versa*, thus demonstrating the existence of two currents in quadrature. When the four points on the armature were joined to the four corners of a square of platinum wire, the wires became incandescent in succession, the glow appearing to travel round the square, and suggesting the idea of the rotary currents.

EDISON MULTIPOLAR GENERATORS AND TRIPLE-EXPANSION ENGINES.

In our issue of January 17, we illustrated and described the Edison multipolar generators, geared directly to the shaft of a triple-expansion engine. The cut illustrates further details of construction, and shows the condensing box and foundation of the engine. The engine is of the triple compound three-crank inverted cylinder, automatic condensing type, well proportioned throughout, having large wearing surfaces which can be easily adjusted. The bedplate to which the main bearing boxes of the crank shaft are cast is strong and is firmly bolted to a massive foundation box which also carries the dynamo frames—thus perfect rigidity between engine and generators is ensured. The crank shaft is of forged steel, fitted with cast-iron balance discs to which the crank pins are fitted. There are two bearings to each crank and an additional large bearing on each end of the shaft to carry the armature. On the shaft are three eccentrics, each operated by its own independent governor, so that the point of cut-off in each cylinder is changed equally with the load, thus doing away with any tendency to race, in case the total load is at any time thrown off or any accident happen. Strong cast-iron columns carry the cylinders which are bolted together, and the engine is strong, compact and well arranged; indeed, these engines are almost fac-similes of the latest and most improved types at present in use on the finest ocean steamships, with necessary additions to render them as highly efficient for electric generating purposes as their prototypes are for marine work. They are calculated for the maximum efficiency point at about 12½ per cent. below the normal maximum capacity of the generator, and have a range to a maximum capacity of 20 per cent. above the normal maximum output of the generator at 160 pounds initial



Edison Multipolar Generator and Triple-Expansion Engine.

pressure and a vacuum of 24 inches, thus allowing each engine, in case of accident to the condensing apparatus, to operate the generator satisfactorily non-condensing. In addition to the many advantages already mentioned these engines when connected to a suitable condenser, will, it is claimed, reduce the consumption of fuel considerably. This is an item of importance in electric light stations, increasing their storage, boiler and engine capacity.

Obituary.

MR. ANDREW B. ULINE.

INFORMATION has arrived here of the death at Nassau, N. P., of Andrew B. Uline, general manager of the Hudson River Telephone Company. Mr. Uline was born in West Sand Lake, Rensselaer County, on July 17, 1836. He was educated at the district school and then went to Indianapolis. In 1868 he went to Albany as agent for the Merchants' Despatch. In 1878 he formed the Commercial Telephone Co., which was subsequently merged with the Hudson River Telephone Co. Mr. Uline was a Democrat and had held the place of Fire Commissioner since 1886. He was a man of warm friendships, and was greatly liked in electrical circles, especially in New York City, where he was a frequent visitor. We understand that Mr. W. D. Sargent, vice-president of the New York and New Jersey Telephone Co., was in Nassau with Mr. Uline.

MR. ANDREW IRVINE.

WE regret to announce the death of Mr. Andrew Irvine, a Western agent of the National Electric Co. of Eau Claire, Wis. We are in receipt of a copy of the special resolutions on his death, adopted by the City of Pekin Electric Light and Power Co. of Pekin, Ill., in which they speak in the highest terms of his ability and character, as evinced in his recent business relations with them,

Literature.

Electric Light Cables and the Distribution of Electricity. By Stuart A. Russell. *New York:* Macmillan & Co., 1892. 311 pp. 5 x 7½ inches. Price, $2.25.

As the title indicates, the subject treated of in this volume is limited to that branch of electrical engineering which relates directly to the properties of conductors and their effective adaptation to the requirements of the various systems of distributing electrical energy for various purposes. That this portion of the applied science has now become of such magnitude and importance as to merit specialization can hardly be disputed, and indeed the French seem to have found it necessary to distinguish by the word *canalization*, that part of a system of distribution that relates only to those trunk conductors, which transmit the energy produced by the generating plant to the extremities of the network of conductors embodying the translating devices.

The book discusses the relative advantages of various conductors and the results most favorable to copper. The important question of the most economical employment of this costly but necessary element of distribution is deduced from the law which was pointed out by Lord Kelvin, and the results of Prof. Forbes' practical experiments. Then follows an inquiry into the effect of rise of temperature on copper conductors, based on the excellent data on the heating of bare and insulated copper wires under different conditions of exposure and protection, derived from Mr. Kennelly's very valuable experiments.

The difference of the resistance of conductors carrying alternating currents is also considered, and the determination of the *virtual* resistance of such conductors exemplified by the convenient table of virtual resistances of different conductors calculated some time since by Mr. Mordey from the figures supplied by Lord Kelvin. Rules and calculations relating to loss of pressure, heating, etc., in their relation to the size of the conductor derived from these modern conceptions and experimental evidence of underlying principles, are presented and on the whole provide a comprehensive résumé of the subject.

Various systems of distribution are critically examined in a manner to be commended,—series, parallel, feeder and multiple systems, besides accumulator, motor-generator transformer and periodic current transformer systems being described. The offsets and disadvantages of multiple systems of more than three wires, and the limitations of accumulator-motor-generator transformer systems like the Chelsea central and sub-station supply, and of series systems like Bernstein's transformer system, are unhesitatingly exposed.

As would naturally be expected, the book describes and illustrates many industrial types of wires for aerial lines and interior installation, cables and conduits for aerial, underground and under-water mains, among them interesting systems in actual use, including the Ferranti mains and Edison tubes. Much practical matter has been incorporated relating to the construction of overhead and underground lines, including detail apparatus, protector instruments, together with data relating to strains on aerial cables supported by bearer wires.

Mr. Russell wisely insists on the importance of systematically testing the conductors of electrical distributing systems, and besides useful hints regarding the same gives methods of making mechanical and electrical tests, including the testing of cables during laying and jointing. On the whole the volume may be credited with embracing the subjects indicated by its unassuming title in a satisfactory manner, and the book will undoubtedly prove useful to constructing engineers.

G. B. P., JR.

Legal Notes.

LANE-FOX vs. KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHT CO.—ON STORAGE BATTERY CENTRAL STATIONS.

A VERY elaborate judgment was delivered on March 20 by Mr. Justice A. L. Smith in Chancery Court in the suit of Lane-Fox *vs.* Kensington and Knightsbridge Electric Light Co. for infringement of patent issued in 1878 to the former. On the part of the defendants it was claimed that the patent was void, owing to the discrepancy between the complete and provisional specifications; further, that the patent was not drawn up in such a way that it was intelligible to an ordinary mechanic without further instructions.

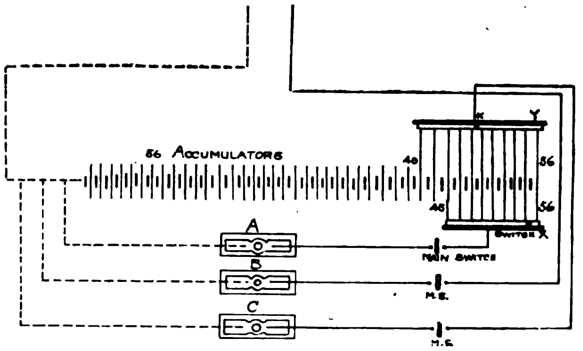


DIAGRAM IN THE LANE-FOX LITIGATION.

In Lane-Fox's final specification it was claimed that "the secondary batteries were to act as reservoir batteries to keep the potential in the mains constant," and for this a means of regulation was specified in the provisional, but omitted in the final specification. Mr. Lane-Fox had come to the conclusion that the special means of regulation was not necessary, as the batteries themselves acted as regulators. This discrepancy was fatal to the suit and the patent was declared invalid.

It need hardly be stated here that secondary batteries require very elaborate regulating switches. Expert opinion was called by both sides, among the witnesses for the plaintiff being Professors S. P. Thompson, John Perry and George Forbes, while for the defendants, among others, Sir Fred. Bramwell, R. E. Crompton, Dr. John Hopkinson and J. Swinburne were called. One of the claims of Lane-Fox, the use of the earth return, was early disallowed in the case, as the Judge had become fully convinced that its use was not practicable. The evidence upon the definition of what was implied was very conflicting; only two cases could be cited in which storage batteries were used and where no further regulating switches were employed. Further, in each case the installation was only small. On this point, too, the Judge decided that regulating switches or devices were necessary for the practical operation of the batteries.

For the defense a model was produced showing the various combinations which could be accomplished by means of the regulating switches at present installed by the defendant company in their two stations situated in Kensington Court and Knightsbridge. A diagram is here given which will readily explain itself. As evidence of the necessity of using regulating devices, the first plan which was installed in the Royal Courts of Justice was instanced. In this case the batteries were ordered to be removed from the building, owing to the lack of regulation, within a few days of being installed. Curves of charge and discharge were freely referred to, showing the rapid rise in potential of the cell just before the boiling point is reached, and much stress was also laid on the rapid fall of potential at the commencement of the discharge with the subsequent prolonged gradual decrease which takes place, until a point is reached, just before the almost total discharge of the cell, where the potential takes another sudden and rapid drop.

It is worthy of mention that, so far as can be recalled, no mention was made by any witness of the use of an automatic break switch. No installation would be complete without one for cutting out the batteries from the charging circuit in case of accidental shutting down of dynamos or other cause. Apart from the discrepancy in the provisional and complete specification the patent was declared not to be sufficiently explicit to allow of an ordinary workman being able to use it without further instructions.

Very eminent counsel were engaged on each side; for the plaintiff, the Attorney General (Sir Richard Webster), Mr. J. Fletcher-Moulton, Q. C., and Mr. Wallace; while for the defendant company, Sir Horace Davy, Q. C., Mr. Finlay and a junior appeared.

JUDGE COXE'S DECISION ON THE PERFORATED STORAGE BATTERY PLATE.

WE are in receipt of the following communication from Mr. Wm. Bracken, president of the Consolidated Electric Storage Co. the exclusive licensees of the Brush storage battery patents:

The newspapers have in the last few days been made the vehicle for conveying to the public the idea that Judge Coxe of the United States Circuit Court for the Southern District of New York had in the case of the Accumulator Company against the New York and Harlem Railroad Company, awarded to one J. W. Swan, and his assignees, the sole and exclusive right to a perforated support plate for storage batteries; that without such a plate as Swan claims no practical storage battery had ever been made, and that this decision postpones indefinitely the use of storage battery cars and the like. We cannot better show how misleading these statements are than to quote from the decision itself. Judge Coxe says:

"The original patent, No. 312,599, dated February 17, 1885, was considered by this court in the case of the Accumulator Co. *vs.* Julien Co., 38 Fed. Rep., 117. The original was held invalid (page 140–142) for the reason that it described and claimed a plate the outer surface of which might be covered by the active material. This construction, in view of the work done by Prof. Eaton was held to be anticipated.

"The theory of the reissue is that the valuable feature contributed by Swan consists in confining the active material in the holes without permitting it to extend beyond them to the surface of the plate. That portion of the original which refers to the coating of the outer surface of the plate has been omitted in the reissue. In other respects the description is unchanged.

The claim is as follows:

> A perforated or cellular plate for secondary batteries, having the perforations or cells extending through the plate and the active material or material to become active packed in the said perforations or cells only, substantially as described.

"This is the claim of the original, except that the word, only, has been added.

"The patent cannot be criticised as a reissue. The claim instead of being broadened is greatly restricted. The application was filed within a reasonable time after the inventor was informed of the facts which made a narrower claim necessary. The facts bring the case within the provisions of section 4,919 of the Revised Statutes.

"The field of invention is, conceded, a narrow one. The counsel for the defendant correctly states that Swan's improvement consists wholly in the idea of putting on the surface of a perforated plate secondary battery, no active material beyond the contents of the perforations; everything except this is conceded to be old."

The date, *de jure*, of Swan's invention is January 18, 1882. Prior to that time Prof. Eaton had filled the perforations, but he had covered both sides of his plate as well. Mr. Brush had rammed or pressed absorptive substances, in the form of dry powder, into grooves or receptacles without covering the surface of the plate. No one had packed active material into holes extending through the plate, confining it entirely to these holes. The combination was original with Swan. Swan was not the inventor of the perforated plate. On the contrary, Judge Coxe took that claim away from him, in the case of the Electrical Accumulator Company *vs.* The Brush Electric Company. Neither has Swan the right to put the active material in the perforations or apply it in any way to a perforated plate, for that has been awarded to Brush.

Swan's claim is the narrow one of putting the active material in the perforations only. His claim does not cover the method of putting the active material in the perforations and at the same time spreading it over the surface of the plate. Neither does it cover the putting of the active material in any manner in grooves, receptacles or perforations that do not extend wholly through the plate. In fact the claim is as narrow as it is of doubtful utility. The progress of the storage battery industry will not be retarded one hour by the decision.

THE ACCUMULATOR COMPANY vs. N. Y. & HARLEM R. R. CO.—A DECISION ON STORAGE BATTERY GRIDS.

THE following is an abstract of the opinion of Judge Coxe in the case of the *Accumulator Company* vs. *N. Y. & Harlem R. R. Co.*, of April 9, 1892, referred to in these columns last week:

This in an action alleging infringement of patent No. 11047, reissued to complainant as assignee of Joseph Wilson Swan. The invention consists in forming the electrodes of secondary batteries with perforations extending through the plates, in which the active material is packed. The original patent was held invalid by this court in the case of *Electrical Accumulator Company* vs. *Julien Company.* (The decision rendered by Judge Coxe, March 18, 1891), upon the ground of having described and claimed plates, the outer surfaces of which were covered with active material, which in view of work previously done by Prof. Eaton, was held to have been anticipated. The theory of the reissued patent is that the valuable feature of Swan's invention consists in confining the active material to the holes, not permitting it to extend to the surface of the plate. The claim of the reissued patent is as follows:

> A perforated or cellular plate for secondary batteries, having the perforations or cells extending through the plate, and the active material or material to become active packed in said perforations or cells only, substantially as described.

The reissue has not broadened, but on the contrary has greatly restricted the claim, and the application was filed within a reasonable time after the inventor had become aware that such restriction was necessary. Swan's date, *de jure*, is January 18, 1882. Prior to this, Eaton had filled perforations and covered both sides of the plate with active material, and Brush had pressed the absorptive material into grooves. No one had packed it into holes extending through the plate, and confined it entirely to the holes. Did it involve invention to do this? It is necessary to remember that we are dealing with a new and abstruse art, where most important results may follow from changes apparently of the most unimportant character. In holding that there is a sufficiency of invention to support the patent, the court has been influenced by the consideration that Swan's electrode is today the electrode of commerce, having largely supplanted all others and being in almost universal use. The advantage of having the active material in small disconnected masses, packed in holes extending through the plate, seems unquestionable. The electrolyte is permitted to reach and act upon both sides of the small masses instead of one side only. Defects which produce buckling and short-circuiting and other disastrous results are entirely remedied by Swan's construction. The step from the electrode of Eaton and Brush to that of Swan seems very short, but standing where these men did, and looking forward to the ideal electrode, avoiding all the difficulties then existing, the steps undoubtedly seemed many and long. If Eaton had scraped the active material from his plates, leaving the holes full, he would have had the invention, but he did not. If Brush had punched out the bottom of his receptacles and had then rammed them full of active material, he would have made a successful structure, but he did not.

As to the infringement, there can be no doubt. The question as to the effect of the expiration of the Danish patent has not been argued, but casual examination has led to the conclusion that it is not for the same invention as Swan's reissued patent. Decree for complainant.

Letters to the Editor.

INSURANCE OF CENTRAL STATIONS.

I AM much interested in your editorial on page 356, of your issue of April 6, concerning insurance of central stations, and the tactics adopted by one central station manager to get his rate reduced, as stated in his communication to you. His method is not new at all; in fact it was tried and worked successfully in hundreds of cases during the two years' life of the Electric Mutual. If it had not been resorted to so generally, and on the other hand, if the insurance of central stations had been given to the Electric Mutual at its low rates instead of using it to beat down the rates of local boards with, the Mutual would have been a strong institution in existence to-day. I fear that although the plan worked so well in the case mentioned, it will not generally work, because the New England mutuals are almost entirely withdrawing from central station risks since the retirement of the Electric Mutual, in which they placed their faith for the selection and care of the risks; and insurance boards are generally "onto" the fact that the mutuals have stopped. In the Southeastern States rates have been advanced, and a movement is on foot for a similar advance in New England, the home of the mutuals, which were used so successfully to pull the chestnuts out.

I hope I am mistaken, but I fear that the great mistake was that the central station men did not fully appreciate the value to them of the Electric Mutual and its allies Time will tell.

I must take exception to the inference that may be drawn from your correspondent's statement that he ran any risk with the mutual companies he had. They were among the best and as solvent and sound as any companies doing business. Since the expiration of their policies on the station in question, the dividends earned have doubtless been paid and after deducting them from the 80-cent rate paid, I wonder if the present rate is "even better." I make the above comments because it is the first time I have seen in print an acknowledgment of the real uses to which the Electric Mutual was so frequently put. It may prove another case of the goose and the golden egg, and if the signs of the times are right it may demonstrate afresh that one cannot have his cake and eat it too.

Only three months ago the Mutual stopped. A great many central station men regret it already.

STEPHEN E. BARTON.

NEW YORK, April 12, 1892.

POTENTIALS AT 500,000 VOLTS.

IN common with many others I have read with much interest Prof. Elihu Thomson's paper on "Dynamic Induction at High Potential and Frequencies" in your issue of March 30, 1892, and as further demonstrating the high insulating qualities of oil and as making us familiar with a very convenient and easily constructed apparatus for obtaining high potentials the paper is of very great interest—but the paper also contains what I believe to be a serious error. Prof. Thomson says he easily obtained sparks of over 31 inches and "so far as can be estimated from available data these sparks were due to potentials of not less than half a million volts."

This of course is a cautious statement, and yet must convey the idea that he thinks such potentials are possible in air at ordinary distances; but in view of the experiments of Mascart and others on striking distances it would seem that it were simply an impossibility to obtain such potentials as 500,000 volts in air, as probably any length of air at ordinary temperature and pressure would break down under a much less electrical stress than 500,000 volts. Referring to the table of results given by Mascart in his second volume of his "Traité d' Electricité Statique," it is seen that for distances not exceeding about 2 cm., between balls 22 mm. in diam. the difference of potential is approximately proportional to the striking distances—and beyond that point the difference of potential increases slowly; at 10 cm., the difference of potential is 119,100 volts while at 15 cm., or 50 per cent. greater, the difference of potential is only 127,800 volts—that is, with an increase in sparking distance of 50 per cent., the voltage necessary is only about 7 per cent. greater. Plotting from Mascart's results a curve whose ordinates are potential differences and whose abcissæ are striking distances, we have a curve which might be called the electric strain diagram of air and shows that the difference of potential in air tends to a limit probably not greater than 150,000 volts and this potential would be capable of sparking any distance, from several inches to possibly many miles.

It may be argued that as Mascart only used a maximum striking distance of 15 cm., nothing can be inferred from his results, as to the potential differences at greater sparking distances, but I think the shape of the curve as far as plotted and our general knowledge of the nature of electrical stresses will allow us to infer with accuracy the shape of the curve up to several feet at least, when it is seen that Prof. Thomson was using probably not over one-third the voltage he suggested. In the light of these experiments of Mascart and others, it is evidently absurd to talk of transmitting electrical energy at two or three million volts on bare wire in air, as such pressures would probably be sufficiently great to spark quite around the earth, but higher pressures than can be used in air might however be used by surrounding the conductor by a material such as oil, having a greater dielectric power than air, as suggested by Prof. Thomson in THE ELECTRICAL ENGINEER of March 23. R. B. OWENS.

DEPARTMENT OF ELECTRICITY,
UNIVERSITY OF NEBRASKA,
April 12, 1892.

Society and Club Notes.

THE BRITISH INSTITUTION OF ELECTRICAL ENGINEERS.

THE wonderful development of the electrical industries during the last decade is nowhere better illustrated than in the gratifying growth and prosperity of the Institution of Electrical Engineers of Great Britain. Founded in 1871, as the Society of Telegraph Engineers, with a membership of 110, its first meeting was held on February 28, 1872, under the presidency of the late Sir Charles W. Siemens. In his inaugural address, the president said that London, being the principal centre of the telegraphic enterprise of the world, was unquestionably the proper seat of such a society, observing at the same time, that the manufacture of submarine cables was almost entirely confined to the banks of the Thames, a circumstance which still remains true after the lapse of 20 years. Mr. Latimer Clark made the following prophetic remarks:

> I feel assured that this society will grow and increase, and that it will ultimately become a large and important institution. If you read the scientific works and periodicals of the day, you cannot fail to perceive that electricity, magnetism and electric telegraphy occupy a large and increasing share of public interest and attention. I hope, therefore, that this society will develop into something more than a mere telegraph society, and that it will gather into the compass of its proceedings a large share of the many valuable and interesting papers which we now see read before other societies, and scattered among other scientific publications. When that time arrives, and not till then, I shall feel that the Society of Telegraph Engineers has assumed its proper function and position in the scientific world.

Within 10 years from the date of organization of the society the prediction of Mr. Clark had been more than fulfilled. The field of the society's labors had not only immensely broadened in its scope, but had extended itself into many new and hitherto unexplored regions of science. In 1889 the name of the society was changed to that of "The Institution of Electrical Engineers," a somewhat unfortunate choice, by reason of its almost exact identity with that of the distinctive title of the sister society in the United States, which was organized in 1884.

The Institution now numbers 535 full members, 1,079 associate, 2 honorary, and 177 foreign members, besides 183 students; a total of 1,976. The list of foreign members in the United States numbers 36, the senior member being Franklin L. Pope, who was elected in 1872. Among the distinguished men who have occupied the presidential chair of the society may be found such names as Sir Frederick Abel, Latimer Clark, Prof. William Crookes, Dr. John Hopkinson, Prof. David E. Hughes, Lord Kelvin, better known as Sir William Thomson, William H. Preece, Sir Charles Siemens, Cromwell F. Varley and many others. The transactions of the society have been issued regularly since 1872, and now number 21 volumes, while the membership extends to almost every country on the globe.

CHICAGO ELECTRICAL ASSOCIATION.

PROF. C. S. COOK, of Evanston, favored the Chicago Electrical Association at its regular meeting April 12th, with a review of Dr. Hertz's researches on electromagnetic waves. These experiments are now familiar to electrical students, and their bearing on both theory and practice is coming to be better understood. Prof. Cook showed how Hertz's work was the fulfilment of Maxwell's speculative theory and how it revealed the close relations between the forms of radiant energy known as light and magnetism.

Following the order in which Dr. Hertz made his varied experiments, from the earlier ones on determining the length of electromagnetic wave lengths to the more recent ones which tend to show the depth to which alternating currents penetrate conductors, the lecturer showed the bearing of these points on our present ideas regarding the transmission of electrical energy. A brief discussion closed the evening's progamme. At the next meeting, April 26th, Mr. F. R. McBerty will read a paper on the "Sparking of Dynamos."

Personal.

MR. J. DOUGLAS DALLAS has established himself as an electrical engineer and electrician at room 511, Mansion House Chambers, London, England. He is well known in this country, where he spent five years in professional work. He was at one time with the Edison General Co. at Schenectady and later with the Railway Department of the Thomson-Houston Co. as an expert. He also had considerable experience with storage batteries.

MR. A. HYDE, who a few months since was placed in charge of the underground cables of the Minneapolis Brush Electric Co., has now been appointed superintendent of the company. The company's plant is now in excellent condition, most of the circuits being underground and working well.

MR. JOHN W. CHERRY, who has been the manager of the Toledo telephone exchange, is removing to Indianapolis to assume his duties as general manager of the exchange in the latter city.

MR. HUNT MAY EARN HIS LIVING.

JUDGE TRUAX, in the N. Y. Supreme Court has dissolved the injunction obtained by default by the W. J. Johnston Co. against W. T. Hunt and the Electrical Age Publishing Co.

This was an action brought by the W. J. Johnston Co. to restrain W. T. Hunt from soliciting advertising for the *Electrical Age*, and the Electrical Age Publishing Co. from employing Hunt.

This case has attracted considerable attention in electrical circles throughout the country.

TRADE NOTES AND NOVELTIES

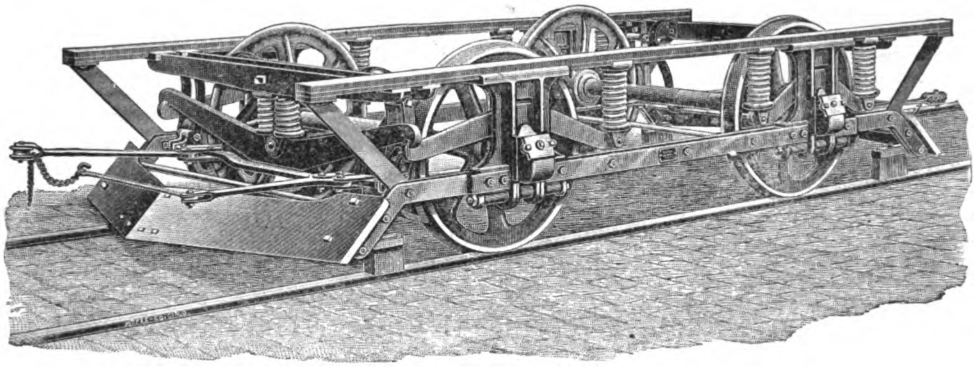
AND MECHANICAL DEPARTMENT.

Know your public, and let the public know you.

THREE RIVERS NEW EQUALIZING MOTOR TRUCK.

In no portion of electric street railway work have greater improvements been made than in the trucks, which, with the advent of the electric motor, demanded many material changes in construction. The latest development in this line is the new equalizing truck for electrical work, manufactured by the Sheffield Velocipede Car Co., of Three Rivers, Mich., which, on account of its novel features and improvements, is attracting considerable attention in street railway circles. The accompanying illustration shows very clearly the principal features of the device, the leading one of which is the simple and effective mechanism for equalization of strains. This principle is considered by street railway men to be of the greatest importance and has been very cleverly carried out by the Sheffield Velocipede Car Co. who enjoy a high reputation for their other specialties in steam railroading and other lines.

One end of the car is carried upon side equalizing bars, long coiled springs being introduced between the truck and the car body, giving exceptionally easy results in riding. The other end of the truck is carried by means of similar side equalizing bars, one end of these bars being cushioned against the main side sill of the car, the other end engaging with a cross-equalizer, attached similarly to the other side, and being cushioned against suitable carrying bars in the centre. The result of this is, as claimed by the manufacturers, a practical three-point suspension for the car body on one end of the truck, the car being supported over each of the wheels, whereas the support on the other end, by means of the cross-equalizer, is carried to the centre of the car. By this means all twisting strains are avoided, and the shocks and jars incident to rapid speed and severe service are very largely absorbed and neutralized.



Three Rivers Equalizing Motor Truck.

The construction is such that the two ends of the truck play freely in a vertical plane without imparting disagreeable oscillation to the car body, and also give greater ease in the matter of curves and uneven track. The wheels of these trucks are ground to an exact match in circumference, after being pressed on the axles, thus insuring not only the perfect pairing of the wheels, but that they shall run with absolute truth with reference to each other.

The bearings, which are all of heavy gun metal, are carefully milled to fit the axles. The boxes are made self-oiling, and will run for a long time without attention. The brakes are arranged in an entirely new plan, giving very much greater power than has heretofore been secured for this purpose and applying it equally to each wheel. The brake shoes are of an improved form, and can be replaced when worn by the removal of a single key, with but the loss of a moment's time. The removal of wheels when worn is accomplished by the taking out of a single heavy bolt on either side, a point that will commend itself to many.

Another feature which should not be overlooked, lies in the fact that the whole framework of the truck, being carried by springs, which are also introduced between the main frame and the motor support, greatly increased elasticity is secured for these parts over that afforded by other devices for this purpose. This very materially assists in relieving strain and lessening breakage of gears and other wearing parts.

The truck is so constructed that the centre is left entirely open for the attachment of the motor, which is very easily gotten at in case attention is necessary, as there is no complicated mechanism in the way. The truck is furnished, properly arranged, for any of the well-known systems of propulsion, and is in use on a number of prominent roads, results showing even more forcibly than had been expected, the great desirability of the special features of the device. A sample truck recently furnished to a large electrical street railway corporation resulted in an order for 20 more.

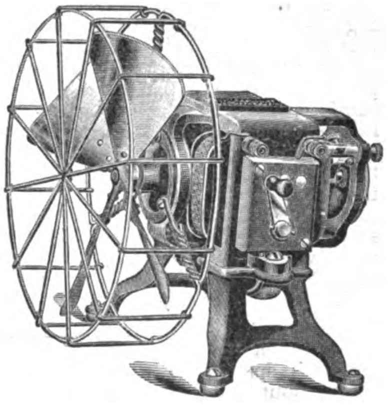
By the use of this truck it is claimed that not only are the electrical repairs very greatly reduced, but greater ease is secured to the passenger, and the life of the whole apparatus, as well as the permanent way, is greatly increased.

INTERNATIONAL TRADING AND ELECTRIC CO.

The International Trading and Electric Co., of the *Times* Building, this city is engaged actively in spite of political troubles in the South American Republics in pushing their goods in these markets. From all accounts their incandescent lamp, the "International," is making an excellent record. It is guaranteed for an average life of 1,000 lamp hours. The company act as agents for export for the Bishop Gutta-Percha Insulated Wire Co., the McCreary Electrical Mfg. Co., Queen & Co., and other high class manufacturers. The officers of the company are: Henry F. Herkner, president; U. T. Fackenthall, treasurer; and W. H. Fleming, who is well known among the electrical fraternity, is general manager.

THE RANDOLPH DAISY FAN MOTOR.

"The greatest economy in consumption of electric energy," is one of the claims of Mr. Randolph, of 425 The Rookery, Chicago, for his fan motor, the "Daisy," shown in the accompanying illustration. This little motor is wound for 110 volts and requires the same amount of current as one 16 c. p. lamp. It has three speeds, 900, 1,200 and 1,800 revolutions per minute. The bearings are very long, are made of lignum vitæ and require but little oil. The motor runs noiselessly and is attractive in appearance. Mr. Randolph is anxious to secure agents in every city to introduce the device.



Randolph Daisy Fan Motor.

NEW CONTRACTS FOR THE SHORT RAILWAY SYSTEM.

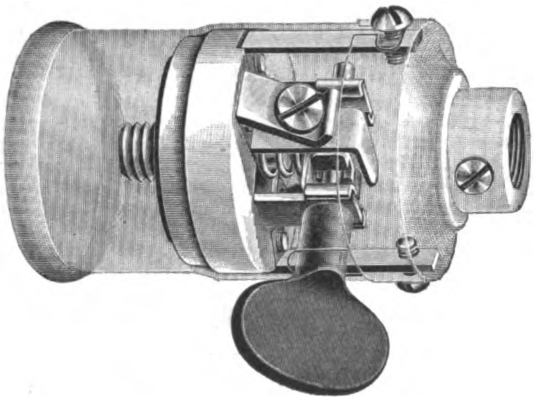
Mr. Edward J. Wessels, the special agent for the Short Electric Railway Co., has just returned from New England, where he has been very successful, his contracts being, we believe, the first secured by the company in New England. It is a very vigorous start, as the orders represent no fewer than 52 motors. The Norwich Street Railway Co. has given Mr. Wessels an order for fifteen 25 h. p. single-reduction motors, to be put into service as soon as possible, the entire road being changed to electricity. The line construction has already been done, and the road will take its power from the plant at Taftville. Mr. E. P. Shaw, Jr., is superintendent.

Mr. Wessels has also carried off the prize at New Haven, where he has sold nineteen single equipments of 25 h. p. single-reduction motors and seven double equipments of the same type, to the New Haven and West Haven Horse Railway Co. The order for the engines and generators has been placed with Westinghouse, Church, Kerr & Co., who will supply three of their large sized direct-connected engine and dynamo units. A third contract is with the Natick, Mass., Street Railway Co., who have decided to add to their rolling stock four 25 h. p. single-reduction Short motors as soon as possible.

The Hygeia Hotel, Old Point Comfort, is just installing a 60 h. p. Ball engine, this being the third furnished this hotel by the Ball Engine Co., Erie, Pa.

THE PERKINS ELECTRIC SWITCH MFG. CO.'S SOCKET.

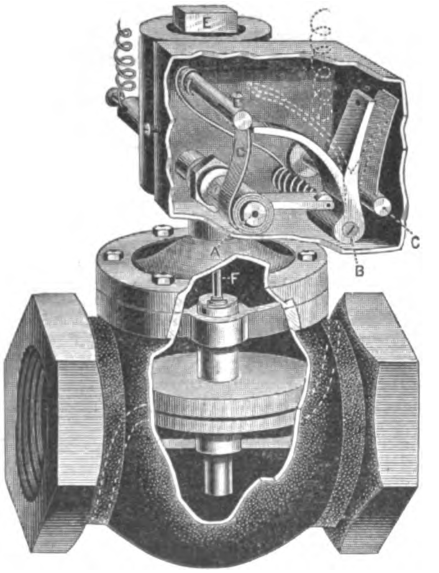
WE illustrate in the accompanying engraving a new socket manufactured by the Perkins Electric Switch Company, of Hartford, Conn. It will readily be seen that this socket possesses a number of novel features and admits of not a few important advantages. Differing from any other socket, there is only one porcelain, which is guided into the shell by two upright brass legs, which are thoroughly insulated from the contact pieces, the screws in the end of which hold the mechanism in the proper position in the shell. The cap is fitted on in the usual way, having a bayonet lock for the screw heads. As will be seen, the contact is made in a novel manner, by means of a parallel brass slide on two upright pieces of sheet brass, which form part of the one pole of the socket. This slide is always kept pressing up against tumbler by means of a small phosphor bronze spring, so that there is good contact at all times, the connection being made by means of the tumbler, when in a vertical position, between the slide and the L-shaped piece of brass shown in the engraving. It is claimed that this socket possesses all the best features of the existing sockets and is the result of careful development. The binding screws are well back from the shell. It is extremely easy to wire, and owing to there being only one porcelain admits of a large knot being made in the wire, for the purpose of hanging the socket, so that the strain is taken off the binding screws.



PERKINS ELECTRIC SWITCH MFG. CO.'S SOCKET.

NEU'S ELECTRIC LEAK AND FLOW DETECTOR.

WE illustrate on this page an extremely novel device intended to protect buildings from damage by water. It is especially applicable to any of the automatic sprinkler systems which are being so generally adopted in large warehouses, factories, etc. A short description is given herewith explanatory of its simplicity. A is a small spindle provided with a cam, not shown, which is actuated by a stem F, moving in a cylinder filled with oil and closed by plug E. The spindle A, carries one arm upon which is a friction roller actuating the contact segment, B. The slightest flow of water or other fluid passing through the valve raises the disc and by means of the stem F, cam and lever moves the contact points B, G and C, thus closing the circuit and at once giving an alarm as well as showing on an annunciator just where the trouble is located. Immediately the cause of the trouble has been removed and the flow stopped, the contacts open and drop to their normal position automatically. There is no impediment to the moving of the valve upward, it being so delicate that drawing a pint of water from a six-inch main will give an alarm. Very little current is required to operate the detector, one cell of primary battery being sufficient under ordinary circumstances.

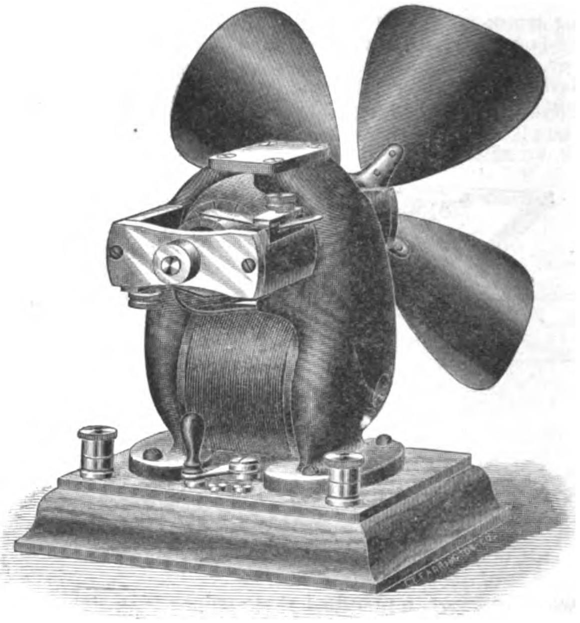


NEU'S ELECTRIC LEAK AND FLOW DETECTOR.

G. S. Neu, of 110 Centre street, New York City, is the inventor and manufacturer of the device.

THE BERNSTEIN FAN MOTOR.

THE accompanying illustration shows a novel and compact form of fan motor recently introduced by the Bernstein Electric Company, of 620 Atlantic avenue, Boston, who claim that it is the smallest and most efficient high-volt motor yet produced. The iron portion is highly enameled and the brass-work finely finished, producing a workmanlike appearance. It is said that the motor runs smoothly without sparking and that the brushes cannot possibly get out of adjustment. Two types are made as shown in the following table:



BERNSTEIN FAN MOTOR.

Type.	H. P.	Speed.	Floor space.	Height without fan.
"I"	1/15	1,700 or 2,000	6 x 6½ in.	7 in.
"G"	1/8	1,600	7½ x 8 in.	9 in.

Several other sizes are made upon the same general lines, intended for heavier work. Agents are wanted everywhere.

QUEEN & CO.'S INSTRUMENTS.

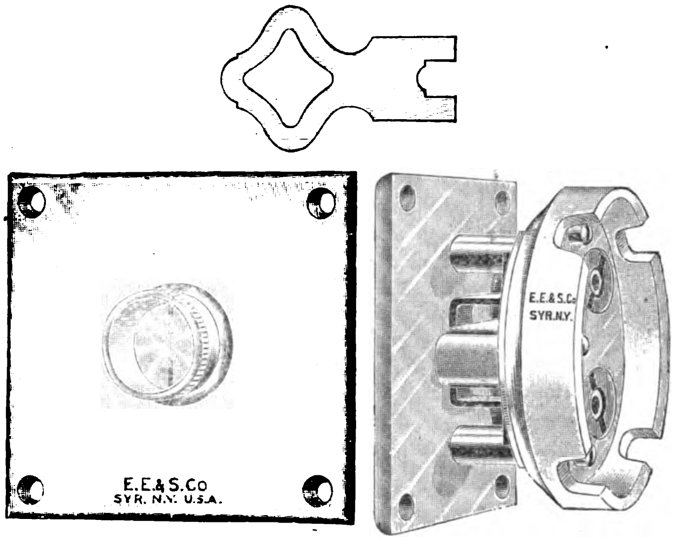
WE are informed by Queen & Co. that they have recently received an order for more than 200 magnetic vane volt and ampere meters from a large manufacturing concern, which instruments are to be installed with the light and power plants put up by this company. The transaction is especially satisfactory to the makers, as a sort of competitive examination was instituted and the magnetic vane type was adopted after careful comparison with other types, as being most suitable in this instance.

APPARATUS WANTED AT PLATTEVILLE, WIS.

MR. W. LOCKWOOD, the superintendent of the Platteville, Wis., Electric Co., writes us that they are in the market for an addition to their plant of a 1,650 incandescent light dynamo, and a power generator, of size not yet determined. They are also in the market for a 1,125 h. p. Corliss engine, to be placed at once.

FLUSH LOCK SWITCH FOR INTERIOR CIRCUITS.

A **very** important feature of electric lighting in residences and fine public buildings is apparatus and equipment that will be attractive and neat. The Electric Engineering & Supply Co., of Syracuse, N. Y., have invented a flush lock switch, illustrations of which are shown below, which is specially adapted to answer this purpose. The working mechanism of this switch is very simple, as shown in the cut, and all parts are warranted by the manufacturers. There is a brass cover which protects all the working parts from any foreign matter when inserted in a plastered wall. All of the switch being entirely concealed, nothing is left to view but the highly finished plate, flush with the wall. This plate can be nickeled, oxidized, engraved or made to match any finish. The striking peculiarity of this switch is its great adaptability for all public buildings, especially for insane asylums and orphanages, where but one person should control the lights. The current can be turned on or off by inserting the key in its receptacle and turning either way, as with the ordinary handle.



Figs. 1, 2 and 3.—Flush Lock Switch.

Upon withdrawing the key, it is impossible for any one to interfere with the lights controlled by the switch. Where it is necessary to place a switch within the reach of children, this device is especially desirable on grounds of safety.

Not only has it these advantages, but it also does away with the unsightly bumps on the walls often seen in the case of the ordinary switch. This company are having repeated calls for these goods, and are at present manufacturing them in large quantities for the trade.

AN ELECTRIC RAILROAD FOR STATEN ISLAND.

Mr. F. R. Chinnock has just sold to a syndicate the franchise for the Prohibition Park Railway, to be operated by a company of that name. The road will run across Staten Island from Port Richmond to Prohibition Park and South Beach, and will be about three and half miles in length. The road will have an Edison equipment of 12 cars, single-reduction gear, and two 100 K. W. generators. The company is now in the market for its steam plant. The syndicate purchasing the franchise, etc., are Royal C. Vilas, president of the New York Air Brake Co.; C. A. Starbuck, and J. C. Thompson, president, of the Eames Vacuum Brake Co. Some of these gentlemen are also interested in the Watertown, N. Y., electric railway. The franchise, which was secured by Mr. Chinnock on February 11, is held to be one that has very great prospective value, although a few months ago it hardly seemed worth getting except to one or two far-sighted men. It is interesting to note that the road will use about 1,100 feet of the Belt Line track. This it does under an order of the court which requires it in return to keep that portion of the road in repair and to allow the Belt Line people use of its terminal facilities. The road will be put in operation as soon as possible in order to get the benefit of this summer's business. The Prohibition Park is a high-class addition to the attractions of beautiful Staten Island.

BARTON & BROWN.

The above firm of attorneys and counselors, Chicago, will remove their patent law offices on May 1, to rooms 1428--1430 Monadnock Building.

UNIVERSAL RADIAL DRILL COMPANY.

The Universal Radial Drill Company, of Cincinnati, Ohio, have issued their calendar for the month of April in their usual style. This time they show their 20-inch swing engine lathe, with the good points of it mentioned on the back of the card.

RAILWAY EQUIPMENT COMPANY.

We publish below the preliminary announcement made by a new company with the above name. Special interest and importance is given to this departure by the fact that it is begun under the direct personal management of Mr. W. R. Mason, who, as is so well known, has made the electric railway field his chosen study, with no small degree of success. We have not yet received any details as to the personnel of the company, but it is understood that it will be fully organized during the current week.

Railway Equipment Company.

Temporary Offices, 617–619 Pullman Building, Chicago.

We beg to call your attention to the above company which has been organized for the purpose of manufacturing and dealing in electric railway supplies for use on all systems. Having had a long and practical experience in all branches of the business, we feel confident of our ability to successfully meet the wants of this branch of the trade. We shall carry in stock large quantities of material needed for the complete equipment and maintenance of electric roads. Prompt shipments can be relied on at all times. We have lately perfected several new line devices which we believe have enough merit to claim the attention of parties about to build or make extensions.

We shall be pleased to advise parties as to the best manner of building and operating such roads. We have no affiliation whatever with any company or individual which will interfere with the exact and impartial conduct of our business. At the earliest possible moment we shall issue a very complete catalogue fully illustrating and describing material of our manufacture and containing valuable data for parties interested in the building or operating of electric roads. In the meantime, we beg to assure the trade that any orders which may be sent to us will be filled promptly and at the lowest market prices.

The writer desires to express to the trade generally his thanks and appreciation of favors granted to him during his connection with a former company, and begs to assure the trade that sincere regard will be paid to their wants and suggestions. Trusting that the conduct of our business may be such as to merit a share of your patronage, we are

Very truly yours,

Railway Equipment Co.,
W. R. Mason.

ORDERS FOR "IDEAL" ENGINES.

The following are among the recent orders received by the Harrisburg Foundry and Machine Works, of Harrisburg, Pa.: Two 10 and 17 x 14 tandem compound Ideal engines, for St. Paul, Minn.; one 18 x 12 plain Ideal engine for St. Paul; three 125 h. p. Ideal engines with corresponding steel return tubular boilers, also pump, heater, piping, etc., for Wilkesbarre and Wyoming Valley Traction Co.; two 18½ x 18 plain Ideal engines for New York City; one 13 x 18 standard Ide engine for Boston; one 125 h. p. standard Ideal engine, steel return tubular boiler, heater, piping, etc., for Georgetown and Tenallytown Electric Railway, Washington; two steel return tubular boilers, for the Allentown Electric Light Company; one 60 h. p. standard Ide engine and steel return tubular boiler for manufacturing purposes, Newville, Pa.; one 25 h. p. Ideal engine and one 50 h. p. Ideal engine for U. S. Naval Observatory, Washington, D. C.; one 50 h. p. engine and steel return tubular boiler for manufacturing purposes, at Newport, Pa. Besides these, they have a number of small Ideal engines ordered for New York City.

HIGH INSULATION RESISTANCE OF RAILWAY INSULATORS.

In a recent issue we mentioned some tests made of the electric railway insulators of Albert & J. M. Anderson, of Boston, and stated that their insulation was found to be 156,000 ohms. We now learn that they were tested up to the very high figure of 156,000 megohms. The tests were made by the Massachusetts Electrical Engineering Co., who say: "The resistance of these insulators was obtained by the direct deflection or substitution method largely used at present for the measurement of high resistances. The voltage used was about 1,100, and a constant sufficiently large to measure to 300,000 megohms was easily obtained. One-minute electrification of the insulator was allowed in each case."

Trenton, N. J.—The People's Electric Light Co. will install at once a 50 K. W. generator to operate motor circuits of 250 volts. This company has taken the matter of handling live wires during a fire into their own hands. At the central station is kept a "St. Louis trimmer's cart" filled with all emergency tools. Both horse and harness are always ready for an alarm of fire, and are generally on the ground ahead of the fire department. The company says this arrangement has proved a paying institution. The Field Engineering Co. are pushing the electric railway rapidly. An unfavorable decree was recently given in court in regard to the State street trolley line, but elsewhere there will be no difficulty.

NEW YORK NOTES.

Doubleday, Mitchell & Co. have secured very desirable quarters in the Electrical Exchange Building, where they will continue to handle the well-known Columbia incandescent lamp, and the specialties of the Consolidated Electric Manufacturing Co. They have just completed arrangements for the representation of the products of the American Circular Loom Company of Boston. They will supply these goods to buyers in New York, New Jersey and Pensylvania.

The Short Electric Railway Co. have removed from the *World* Building to the Mills Building, 35 Wall street. The change has been made imperative by the increase of business and the need for more room. The company will have in their new office a fine display of Short railway apparatus, and every convenience for the transaction of business. Mr. Edward J. Wessels, the special agent, will have his headquarters there.

Search Lights.—Unprecedented success in the introduction of the excellent search light manufactured by the Electric Construction and Supply Co. has had the effect of bringing in such a large number of orders from steamship and transportation companies generally that the manufacturers of these lamps are compelled to work their large force of employees well-nigh on to the "wee sma hours."

The Roy Valve Company, 15 Cortlandt street, are sending out a nicely illustrated catalogue and price list. The little book also contains valuable testimonials as to the very desirable work done by their valves under severe tests. Although but a short time on the market, the "Roy" valve has proven a "winner."

Stanley & Patterson, manufacturers of electrical house furnishings, are about ready to place on the market several specialties of interest to the supply trade. They are sending out a very neat pocket price list and catalogue containing some illustrations of their novelties.

Mr. Ralph L. Shainwald, of the Standard Paint Co., makers of the famous P. & B. compound, has just returned from a flying visit to Chicago and Detroit. The run was a most successful one, several handsome contracts making the return trip with Mr. Shainwald.

Dr J. Graham Scott died at his home, No. 17 East Twenty-first street, last week of acute rheumatism. He was born in Philadelphia on September 10, 1849, and was educated at Jefferson College. He practiced his profession for a time in San Francisco and then came to New York, where he organized the Scott Electrical Manufacturing Company, of which he was president and general manager. He contributed many articles on medical and electrical subjects to various journals and periodicals.

WESTERN NOTES.

The Electric Appliance Company have closed arrangements to represent the Security Insulator Company in the West, and will carry a large stock of their specialty. The Security insulator is one of the most notable of the recent improvements in the direction of a higher grade of material for construction. It combines the desirable features of both insulator and cleat. By its use the wire is held firmly by the insulator without the use of tie wires or other fasteners. The greater the strain on the wire, the tighter it is held by the insulator, but without in any way injuring the insulation. Another point in its favor is that its contact with the wire has the smallest possible surface, thus increasing the insulation resistance of the line.

The Franklin Electric Company, of 535 Delaware street, Kansas City, has secured the contract for wiring the Capital Building at Topeka, Kan. It is also putting in a 500-light Edison plant at Rockport, Mo., and has been retained as constructing engineer for Pierce City, Mo. All this work has come in during the past week.

The Western Electric Co. has just begun wiring the new German Opera House at Chicago and will use Simplex wire throughout. No wonder George Cutter is wearing a Sunday-go-to-meeting smile on week days!

Gladstone, Mich.—Edwin J. Tice has secured a 24-year franchise and has contracted with the Edison General Electric Co. for a 1,000-light plant. A full company has not yet been formed.

The United States Electric Light Company has been awarded the contract for two 800-light dynamos for the Jackson county court house, Kansas City.

CANADIAN NOTES.

The Toronto Construction and Electrical Supply Co., office and salesrooms 63, 65, 67 and 69 Front street, west, Toronto, has issued its first catalogue. It is a very handsome and interesting production of quarto size, well printed and solidly bound. It enumerates a large variety of apparatus and supplies, with prices, etc., and shows every sign of enterprise and business acumen.

NEW ENGLAND NOTES.

O. S. Platt.—The factory of O. S. Platt, Bridgeport, Conn., manufacturer of the well-known New England switch, has been taxed to its utmost capacity for some months past turning out these excellent switches. There is no doubt that with improvements recently made in this switch it is one of the best on the market. The contact bar is now arranged so as to slide up and down a standard instead of moving in a saddle as heretofore. This leaves a nice space inside with plenty of room for making connections, leaving little chance for short-circuits, etc. Another improvement is the placing of a fibre collar on the outside of the shell. This collar is supplied with an inner thread, which when screwed up prevents the loosening and dropping down of the shell, which is a disagreeable feature in a great many switches. A very handsome flush switch, also manufactured by Mr. Platt, has been in great demand for several months. He also makes a specialty of the manufacture of dynamo gas igniters.

The Berlin Iron Bridge Co, of East Berlin, Conn., have taken the contract to build a producer building for the Solvay Process Co., of Syracuse, N. Y. The building will be 30 feet wide, by 100 feet long and three stories high built entirely of iron, even the floors being made of plate iron in order that there may be no woodwork about the building to take fire.

HUDSON RIVER NOTES.

Cohoes, N. Y.—The directors of the Troy and Lansingburgh Railroad have been endeavoring to secure the consent of property owners on Remsen and Main streets for a new road to be operated by electricity from the stone bridge, North Mohawk street, to Remsen, to White, to Main, to Saratoga street and thence to Troy via the White line. If the company is successful in securing the consent asked for, the Mohawk street branch from Ontario to the junction of Main and Saratoga streets will probably be abandoned, and the White line cars will then run over the new route.

Troy, N. Y.—The Troy City Railroad Company has secured a site for the power station, by a purchase from the Marshall estate. Consideration $2,000. The station is to be of brick, 100 x 90 feet, with high-truss iron roof. Plans have already been prepared by Architect McIntyre, of New York City, and the work of construction will begin as soon as the weather permits. It is the intention of the management to hasten the electrical equipment of the road, and the promise has already been made of electric cars running by June 1, next.

Newburgh, N. Y.—The Edison Illuminating Company are to add at once 200 h. p. of dynamos to their plant. These will be set up temporarily until a new station can be built. The Newburgh Electric Light and Power Company will also rebuild at once. Their plant is at present overloaded, although a 65-light arc and a 650-light alternator have just been started.

West Troy, N. Y.—The dynamo for the additional lighting recently contracted for by the village trustees, has at last arrived, and is now being placed in position. The additional lights ordered have been located and wires strung, so that it is expected the power will be supplied in a very few days.

West Troy, N. Y.—The works of J. M. Jones & Son, at West Troy, present a very lively appearance. A number of large orders have been lately received including one for 150 double trucks for the West End Street Railway, Boston. The company has a well-established reputation for the highest class of work.

Poughkeepsie, N. Y.—The Poughkeepsie Electric Light and Power Company will at once enlarge and remodel their station. It is intended to replace all the high-speed engines with low-speed. Probably the electric railway will also be built soon.

PHILADELPHIA NOTES.

The "King" Annunciator made by Partrick & Carter Co., of Philadelphia, is one of the most successful specialties ever introduced by that house. It fills all the requirements of a low-priced and perfect working annunciator, and is just the thing for contract work where the finely finished instruments are not demanded.

At a recent election of the Indianapolis Brush Electric Light and Power Company, Indianapolis, Ind., John Caven, Indianapolis, was elected president; J. Potter, Cleveland, Ohio, treasurer; S. M. Hamill, Cleveland, Ohio, secretary; John Caven, J. Potter, S. M. Hamill, directors.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XIII. APRIL 27, 1892. No. 208.

A PHOTOGRAPHIC STUDY OF NON-ARCING METALS.

BY

Alexander Jay Wurts.

MR. R. G. FESSENDEN, in his article[1], has described some very interesting experiments which he has performed in his investigation of the causes for the suppression of the arc, and the results of these experiments seem to have inclined him to the theory that a pure vapor of the metal is formed between the electrodes, rather than a vapor consisting of the oxide of the metal.

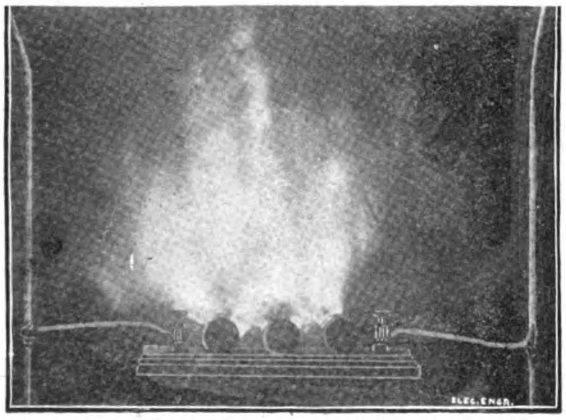


FIG. 1.

In connection with my original experiments, the question naturally occurred to me as to what was the real constitution of the vapor which appeared to be formed, and while I felt that it might be a pure metal vapor, I have always been somewhat inclined to the theory that there is an oxide present. I did, however, at one time test the non-arcing property of metals with electrodes immersed in a hydrocarbon oil, and found that under these circumstances I was unable to maintain a thousand-volt short-circuit across two air-gaps of $\frac{1}{32}$ of an inch each.

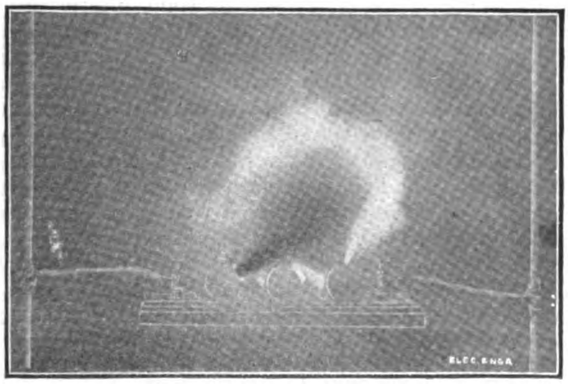

FIG. 2.

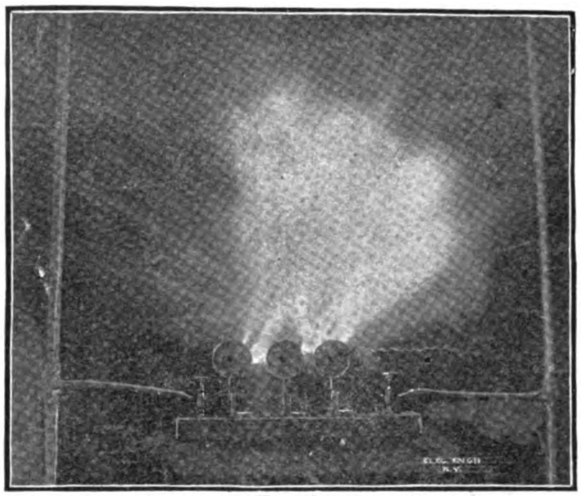

FIG. 3.

This result seems to indicate that the vapor contained no oxygen, because none could be present within the oil, and yet there are other considerations which favor the idea that the vapor is usually wholly, or at least in part, an oxide. Thus, each of the pure non-arcing metals under the conditions of a short-circuit deposits on the surfaces of the electrodes an oxide which in each case possesses the characteristics of some oxide of the particular metal used. Possibly, however, the pure-metal vapor theory is the correct one, and I am pleased to see it discussed.

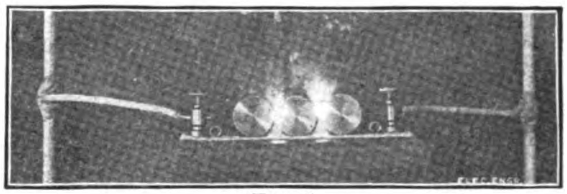

FIG. 4.

It is interesting in this connection to notice that all of the non-arcing metals thus far pointed out are notably diamagnetic. This may be only a coincidence, or there may be in reality some relation between the diamagnetic and the non-arcing properties of metals. Thus, bismuth, antimony, zinc, cadmium and mercury are all peculiarly diamagnetic. Lead also is a diamagnetic metal, and I have made some interesting and satisfactory experiments with it. Although lead has been notorious for its arcing powers when used as a fuse, yet it must be remembered that in order to obtain the non-arcing effects with high potential currents, the air-gap must be exceedingly small.

I therefore made a set of three lead electrodes or dischargers, giving two air-gaps of $\frac{1}{32}$ of an inch each, and, on testing, found that at the instant the short-circuit was established, the arc seemed to hesitate, but the lead quickly reaching its melting point, the small air-gaps were destroyed, and the arc then assumed large proportions. I then repeated the test, this time taking precautions to avoid, if possible, the melting of the lead. For this purpose I made a set of three dischargers, as before, consisting of 50 per cent. copper and 50 per cent. lead, upon the theory that if lead is a non-arcing metal there would be a sufficient quantity of that metal present to suppress the arc, just as in the zinc-brass electrodes there is a sufficient quantity of zinc to interrupt the short-circuit while the copper adds toughness to the electrodes. My tests with the lead-copper electrodes were singularly successful, and upon examining the electrodes after three consecutive tests I found that each short-circuit had formed a small smooth spot upon the surfaces of the electrodes, and that a globule of lead seemed to have been drawn to the surface at these points.

---

[1] THE ELECTRICAL ENGINEER, April 6, 1892.

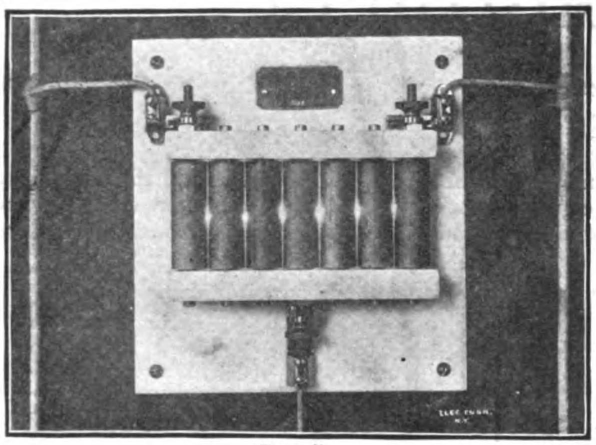

FIG. 5.

The diamagnetic properties of tin are well known, and it is therefore interesting to note that this metal seems to be entirely devoid of non-arcing properties; even a mixture of tin and copper, forming a tin brass, possesses none of the qualities which are so manifest in the case of zinc brass.

I have recently taken some photographs of the arcs between electrodes of non-arcing metals for the purpose of studying the results and gaining further information upon this interesting subject. The different results obtained by the use of small and large air-gaps are especially noticeable in these photographs.

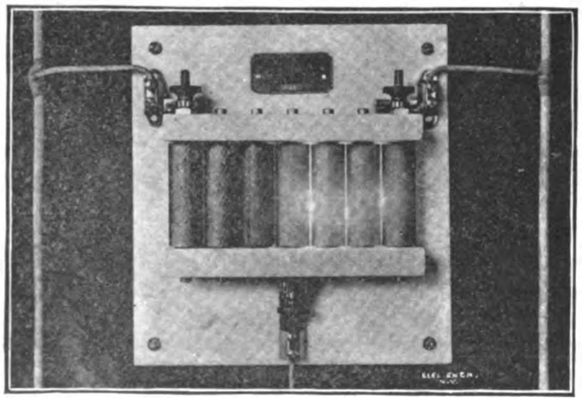

FIG. 6.

Fig. 1 illustrates a 1,000-volt short-circuit across two air-gaps of $\frac{5}{8}$-inch each and between non-arcing metal electrodes.

Fig. 2 is a view of a similar short-circuit across the same air-gaps.

Fig. 3 represents a 1,000-volt short-circuit across two $\frac{1}{2}$-inch air-gaps.

Fig. 4 is a similar short-circuit across two $\frac{1}{16}$-inch air-gaps. In this case the arc was mostly due to the fusing of the tinfoil used in starting the arc, for the circuit was instantly interrupted without injury to the electrodes.

Fig. 5 represents a non-arcing metal lightning arrester suitable for 1,000-volt incandescent alternators and alternating current and pulsating current arc machines. The air-gaps are $\frac{1}{32}$ inch and the arcs shown are due to the short-circuit of a 1,000-volt incandescent alternator. With $\frac{1}{32}$-inch air-gaps the interruption of the short-circuit is instantaneous and merely causes an almost imperceptible flicker in the voltmeter.

Fig. 6 represents the short-circuit across three air-gaps of the same arrester, which in actual practice would be from line to ground. After repeated short-circuiting these non-arcing metal cylinders are not roughened or burred sufficiently to be preceptible to the touch. The short-circuit, however, leaves a small bright spot surrounded by a black deposit, the latter being presumably caused by the fumes of the tinfoil used for starting the arc.

Fig. 7 illustrates a 1,000-volt short-circuit across two $\frac{1}{16}$-inch air-gaps between carbon electrodes.

There are two curious features to be noticed in connection with these figures: First, the reduction of the arc with the reduction of the air-gap; second, the apparently violent repulsion of the arc between non-arcing metal electrodes as compared with the evenly diffused arc between the carbon electrodes. In connection with diamagnetism, these repelling arcs are very suggestive.

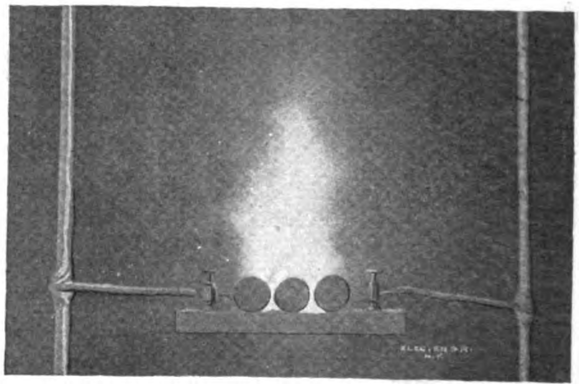

FIG. 7.

SELF-DISCHARGE OF ACCUMULATORS.

DR. KRÜGEL, of Berlin, gives an account in the *Elektrotechnische Zeitschrift* of the result of some interesting and important observations upon the discharge of the negative plates of secondary cells on open circuit. The observations were carried out upon Tudor cells. In an installation it had been remarked that the capacity of a battery was much less than that guaranteed, and that the battery, left by itself, became discharged in a few hours. A careful examination showed that the negative plates only were discharged, the metallic lead becoming oxidized with much disengagement of hydrogen. Other negative plates were put in their place after a strong charge, and the battery now acted well. Numerous tests and analyses showed that the cause was due to the presence of foreign metals dissolved in the electrolyte, which were deposited during charge on the negative plates, where they form couples with the reduced lead. In particular, in the acids giving this effect were found copper, arsenic, antimony, molybdenum, and platinum, the latter having a decided effect even if only in quantities of one-millionth. The manufacturers now only use the acid after having precipitated the metals by sulphhydric acid.

SCIENTIFIC ELECTRO-MEDICAL APPARATUS.

BY

James Bowstead Williams M.D.

The accompanying illustration is reproduced from a photograph of electro-medical and surgical apparatus, invented and made by the writer for his own use while a practitioner of medicine in San Francisco, Cal.

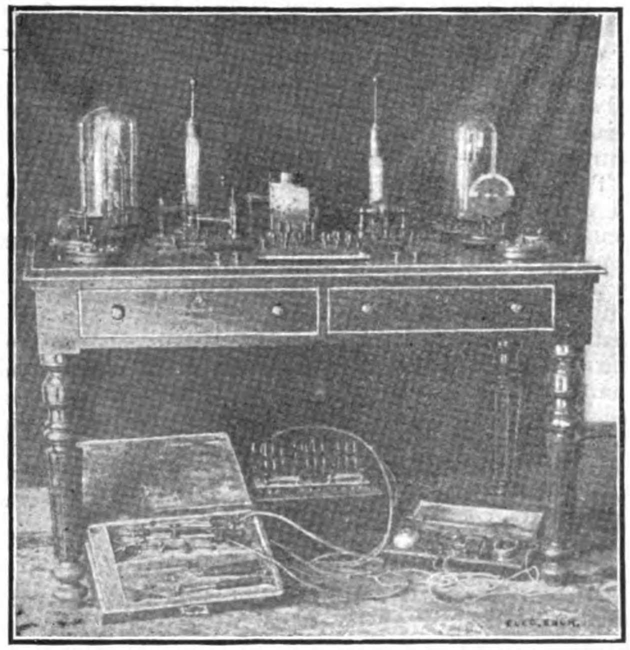
The electro-medical apparatus, shown upon the table was considered to be the first complete apparatus of its kind ever made. It was first illustrated and described in the *Mining and Scientific Press*, of March 12, 1881, published in San Francisco, and the description was subsequently copied into other journals. This apparatus complete consisted of the following named instruments: 1. A battery of 60 gravity cells. 2. Two circular switches, for selecting the current from any number of cells without interrupting it while being increased or diminished. 3. A cylindrical commutator, for reversing the current from the battery. 4. A combined commutator and interrupter, driven by a belt and pulleys, for rapidly reversing or interrupting the galvanic current. 5. A six-lever switch, for switching the battery current, without interruptions, into and out of the principal parts of the apparatus. 6. An upright galvanometer, for testing the current from the battery, and, when used with the switches above named, to indicate the position of breaks or crosses, whether in the battery, the various instruments, or the connections of the apparatus. 7. An astatic galvanometer, for indicating the strength of the galvanic current while passing through the human body, or parts thereof. 8. A faradic rheotome, capable of being adjusted to a wide range of vibrations per second. 9. An induction coil containing two primary and six secondary helices, enclosing a bundle of annealed iron wires. The electromagnets of the rheotome and the primaries of the coil were so wound that the two instruments could be operated by *any* number of cells of the battery. 10. A rheotome, driven by clockwork, for interrupting the galvanic current (the faradic also, if desired) 1, 2, 4, 8, 12, and 16 times per second. 11. Two upright water rheostats, used as shunts for regulating the strength of the Faradic and galvanic currents. 12. A condenser for use with the induction coil, when severe shocks were to be administered. 13. Plug and lever switches, for controlling the action of the different parts of the induction coil, rheotomes, etc.

These instruments were suitably joined together and to the battery by insulated wires secured to the under surface of the table, and they could be used singly or in combinations by means of the various switches, according to their functions. After passing through the instruments, the faradic and galvanic currents were conducted to two pairs of binding posts, and from these, through conducting cords, to the electrodes, for application to all portions of the human body.

The surgical apparatus—that shown underneath the table—consisted of a galvano-cautery with a complete set of electrodes, and a bullet explorer. The generator of the galvano-cautery consisted of nine zinc and twelve perforated carbon plates, each six inches square, placed in three prepared wooden cells which contained the exciting solution. All of the plates were permanently secured to the cover of the cells. By means of switches, the three cells could be used in series, or in multiple arc. Each zinc was connected with a compound switch, by means of which it could be instantly joined electrically with *any* other zinc, or disconnected from it, by simply raising or lowering a lever, no matter how many of the cells were being used, or how they were joined up. As the plates were large, and the battery fluid strong, abundant, and very constant in strength, the current from three zincs, (and their accompanying carbons), whether belonging to the same cell or to different cells, was sufficient to heat all the electrodes, except those which contained a considerable length of platinum wire. This being the case, the value of the compound switch will readily be appreciated, since when one set of plates became polarized, another set could be instantly substituted for the first, by the mere raising and lowering of levers.

This cautery, completed in 1882, was first described in the *Mining and Scientific Press*, and afterwards favorably noticed on the editorial page of the *Electrical World*, of October 11, 1884. All of the electrodes of the cautery were contained in one case—that shown in the centre—and were of original and special design.

The bullet explorer consisted of three parts: The electrodes, flexible conducting cords, and a case containing battery, indicators, and switches. Each electrode consisted of a vulcanized rubber tube, about 13 inches long, containing two fine insulated copper wires. Each wire terminated at one end in a binding-screw, and at the other, in a small ball of pure gold. The gold balls were fastened in conical pieces of hard rubber of various sizes and shapes, and were so arranged that both would make contact with either flat, convex, or concave surfaces. The electrodes were of various degrees of flexibility, so that they could follow the paths made by bullets, whether the paths were straight or crooked.



THE WILLIAMS ELECTRO-MEDICAL APPARATUS.

The indicators consisted of a vibrating bell, and an upright detector, either of which could be used by means of switches. They were operated by one or two bichloride of mercury cells. The conducting cords were about eight feet long, and, with the electrodes, could be packed in the case.

The operation of the explorer was quite simple. The apparatus being properly arranged, as soon as the balls on the electrode or probe came in contact with a piece of metal, a circuit was established through the metal, electrode, conducting cords, etc., and the bell would ring, or the needle of the detector be raised from a normal horizontal position, according as the bell or the indicator had been connected by means of the switches.

This explorer was completed in 1885, and was described in an editorial in the *Mining and Scientific Press*, and noticed in other papers.

THE PRACTICAL MANAGEMENT OF DYNAMOS AND MOTORS.—IX.

BY

Francis B. Crocker and S. S. Wheeler.

CHAP. VII.

DIRECTIONS FOR TESTING DYNAMOS AND MOTORS.

THE matter of testing dynamos and motors is of special importance since it is only by a thorough test that either the manufacturer or the user can determine whether a certain machine is up to the standard. Nevertheless it is difficult, if not impossible, to find in books or journals anything like a complete system of testing methods applicable to dynamos or motors. Each electrical manufacturer or engineer has collected by experience certain methods, but these usually apply to particular forms of machine or testing apparatus and moreover are often guarded as trade secrets.

The following methods cover the various facts about a dynamo or motor which one is likely to want to test. Under each heading exact methods are given which should, of course, always be preferred; but wherever possible we have also given simple, rough methods for emergencies or other cases in which a dynamo or motor may have to be tested without the accurate and expensive instruments required for the more refined methods.

This subject differs from our chapter on "Locating and Remedying Troubles in Dynamos or Motors," in the fact that the other relates to actual faults which are already apparent, whereas testing applies to any machine whether in perfect working condition or containing some latent fault which a test brings out and anticipates. The testing methods here given can also be used as supplementary to the methods for locating troubles in cases where a more complete investigation may be desirable. In testing any machine it is well to follow as nearly as possible the directions given by its maker and try it under the conditions for which it is intended, in regard to voltage, current, speed, etc. Tests of dynamos and motors may cover any or all of the following points:

1. ***Adjustment*** and fit of parts.

2. ***Mechanical Strength*** of parts against breaking or displacement.

3. ***Friction*** of bearings and brushes.

4. ***Balance*** of armature and pulley.

5. ***Noise.***

6. ***Electrical Resistance*** of conductors and insulation.

7. ***Voltage,*** E. M. F., "drop" or fall of potential, etc.

8. ***Current*** in field, armature free and loaded.

9. ***Speed*** of armature, free and loaded.

10. ***Torque or Pull,*** standing or running.

11. ***Power,*** electrical and mechanical.

12. ***Efficiciency,*** electrical and commercial.

13. ***Heating*** of armature, field magnet, bearings, etc.

14. ***Sparking*** at commutator.

15. ***Magnetism,*** total flux, intensity, leakage and distribution.

16. ***Line or Circuit*** testing for resistance, insulation, faults, etc.

1. ***Adjustment*** and the other points which depend merely upon mechanical construction are hardly capable of being investigated by a regular quantitative test, but they can and should be determined by thorough inspection. In fact a very careful examination of all parts of a machine should always precede any test of it. This should be done for two reasons, first, to get the machine into proper condition for a fair test, and second, to determine whether the materials and workmanship are of first-class quality and satisfactory in every respect. A loose screw or connection might interfere with a good test, and a poorly fitted bearing, brush holder, etc., might show that the machine is badly made.

If it is necessary to take the machine apart for cleaning or inspection the greatest care should be exercised in marking, numbering and placing the parts in order to be sure to get them together in exactly the same position as before. In taking apart or putting together a machine, only the minimum force should be used. Much force usually means that something wrong is being done or in a wrong way. A wooden mallet is preferable to an iron hammer, since it does not mar or strain the parts so much. Usually screws, nuts and other parts should be set up fairly tight but not tight enough to run any risk of breaking or straining anything. Shaking or feeling each screw or other part will almost always show that some one or more of them are too loose or too tight, or otherwise out of adjustment.

2. ***Mechanical Strength*** of a dynamo or motor is best specified by stating that it should be above question. The base, bearings, shaft, armature, field magnets and other main parts of the machine should not spring even one one-hundredth of an inch with any reasonable force that may be applied to them. There has long existed a craze for very light dynamos and motors, as a result of which, strength, rigidity, durability and satisfactory qualities in general have been sacrificed to reduce weight. There is certainly no sense in this. For stationary machines and even for ship dynamos or railway motors good solid frames, bearings, etc., are much better than light ones.

The magnetic attraction between the field and armature is often very great, and may amount to hundreds, or even thousands, of pounds. This tends to draw the pole-pieces against the armature, or spring the armature shaft if the armature is even slightly nearer one polepiece than the other. It is well to magnetize the field by putting the proper current through its coils and see if it produces any reduction of the clearance or other displacement that is appreciable to the eye or even to any ordinary measurement. The effect of the maximum pull of the belt or any other legitimate stress may be tested in the same way.

In addition to this all the parts of the machine should be scrutinized to see if they are of adequate size and proper proportion.

3. ***Friction.***—The friction of the bearings and brushes can be tested roughly by merely revolving the armature by hand and noting if it requires more than the normal amount of force. Excessive friction is quite easily distinguished even by inexperienced persons. Another method is to cause the armature to revolve by hand or otherwise and see if it continues to revolve by itself freely for some time. A well-made machine in good condition will continue to run for one or more minutes after the turning force is removed.

A method for actually measuring the friction consists in attaching a lever (a bar of wood, for example) to the shaft or pulley at right angles to the former. The force required to overcome the friction and turn the armature without current is then determined by known weights or, more conveniently, by an ordinary spring balance. The friction of the bearings alone, that is, the pull required to turn the armature when the brushes are lifted off the commutator and there is no current or magnetism in the field, should not exceed 1 per cent. of the total torque or turning force of the machine at full load. When the brushes are in contact with the commutator with the usual pressure, the friction should then not exceed 2 per cent., that is, the brushes themselves should not consume more than 1 per cent. of the total turning force. When the field magnetism is at full strength, and the brushes are on the commutator, the maximum friction or pull required to turn the armature should, then, not exceed 4 per cent. of the total torque.

This torque or pull in pounds in the case of any machine may be calculated by the formula:

$$\text{Torque} = \frac{\text{H. P.} \times 33{,}000}{6.28 \times R \times S}$$

in which H. P. is the horse-power of the machine at full load, R is the radius or length in feet of the lever used in the test, and S is the speed of the machine in revolutions per minute at full load.

Another method of measuring the friction of a machine is to run it by another machine used as a motor and determine the volts and amperes required, first, with brushes lifted off and no field magnetism; second, with brushes on commutator but no magnetism; and third, with full strength of field magnetism giving maximum friction. The torque or force exerted by the driving machine is afterwards measured by a Prony brake in the manner described hereafter for testing torque; care being taken to make the Prony brake measurements at exactly the same volts and amperes as were required in the friction tests. In this way the torques which were exerted by the driving machine to overcome friction in each of the three first tests are determined, and these torques compared with the total torque of the machine being tested, as calculated by the formula just given, should give percentages not exceeding those stated above for the maximum values of friction.

Tests for friction alone should be made at a low speed because at high speeds the effect of Foucault currents and hysteresis enter and materially increase the apparent friction.

THEORETICAL ELEMENTS OF ELECTRO-DYNAMIC MACHINERY—II.[1]

BY

A. E. Kennelly

POTENTIAL.

ANY steady distribution of magnetic flux is subject to a potential except within the substance of conductors carrying electric currents. That is to say, it is possible to assign to each point of the field a numerical value, such that its gradient, or rate of change in any direction shall represent the corresponding component of flux intensity in that line. In recognizing a distribution of potential in space, we therefore erect everywhere an imaginary numerical scaffolding, each point being invested with its appropriate magnitude and sign. The direction of maximum gradient in the scaffolding at any point, is the direction of the flux, the steepness of the grade being the flux intensity. The plane normal to the direction of maximum gradient will also be the local plane of no gradient or of level potential. If surfaces are formed by the colligation of all points having equal potentials, they will be equipotential surfaces. There will be no flux in the plane tangential to such a surface, and the whole flux will be normal to them. It is also evident that the steeper the grade, the closer will be the successive equipotential surfaces, just as in the case of contour lines on a map of levels; so that where the flux density is great the surfaces follow in rapid succession, spreading apart again where the intensity is low.

In fact, the intensity is the reciprocal of the distance between adjacent surfaces whose potential differs by unity, as represented by the equation:

$$B = -\frac{dP}{dn};$$

where P is the potential and n the distance measured along the normal to the equipotential surface, a condition condensed into the notation

$$B = -\nabla P.$$

The negative signs are here appended in order to preserve the convention that the direction of the flux shall be down grade, or the direction in which the potential falls.

If the maximum gradient of potential at a given point is at the rate of, say, 500 units (ergs) per centimetre of distance, the flux density at the point will be 500 C. G. S. lines per square centimetre. As the conception of magnetic potential has important practical applications, we shall proceed to examine its distribution in a few cases.

The simplest instance is probably that of an indefinitely long straight wire of circular section carrying a steady current. Fig. 8 represents a plane drawn perpendicularly through such a wire, carrying a current of 100 / 4 π, or 7,958 C. G. S. units (79.58 amperes, since the absolute unit of current in the electromagnetic system is 10 amperes). The reason for selecting this particular current strength is merely to secure graphical simplicity. The current is supposed to be passing upwards through the wire from the plane towards the reader. The equipotential surfaces for such a wire are radial planes through the axis. They commence, however, not at the axis itself, but at the surface of the wire, because within the substance of the conductor there is no potential, and they have no exterior boundary, or, in other words, terminate at infinity. The traces of 10 such radial planes are shown equidistant in the diagram, and on each of these the potential has a constant value. Selecting any one plane as O B, we find, however, no determination of its absolute numerical value from the conditions of the problem, and we may therefore assign to this plane any numerical value we please, positive, negative, or zero; but having once selected it, the whole system immediately assumes definite numerical configuration.

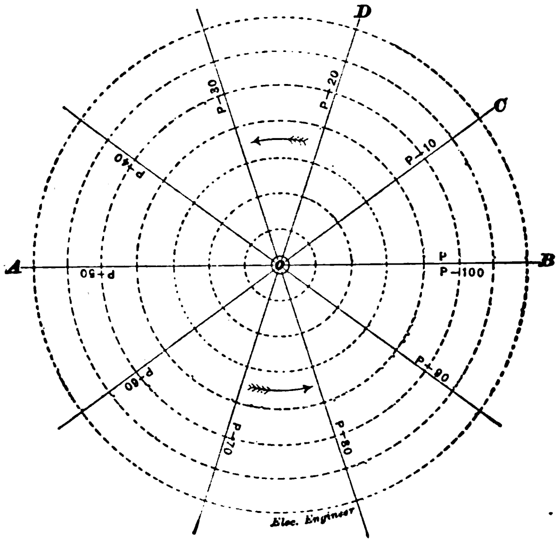


FIG. 8.

Call the potential of OB, P, then the conditions determine that the potential of O C will be $P - 10$; that of O D will be $P - 20$; and so on. Between any two successive planes here represented, it would of course be possible to insert nine equidistant and intermediate planes whose potentials would differ by one unit in succession, while any number of other planes might again be crowded between the unit planes, representing definite intermediate fractional potentials.

Since the flux density is the rate of fall of potential, it is clear that B must have the direction down grade as shown by the arrows, and that it must be at each point normal to the radial plane or tangential to the circle drawn through the point and concentric with the wire. The flux will thus be confined to concentric circles and a few of these whose number is unlimited are represented in the figure by the dotted lines. A free north-seeking pole brought to any point of the field would be carried by the flux round the circle passing through that point in the direction of the arrows.

---

[1] Copyrighted 1892 by A. E. Kennelly.

It is evident from the figure that the distance between any pair of equipotential planes increases uniformly with the distance from the axis; and since the flux is inversely proportional to the distance of these planes, it follows that the intensity varies inversely as the distance from the axis.

If we follow the potential down grade from plane to plane, and complete a circle round the wire, we find that the plane O B which at the outset had the potential P now assumes the potential $P - 100$. Also a second circuitation finds this potential changed to $P - 200$, and so on, for any number of turns. The potential of any plane is thus capable of an indefinite number of values successively differing by 100. In other words the potential is cyclic and multiplex. The gradient is definite, but the absolute elevation above datum is indeterminate. This cyclic property is characteristic of magnetic potentials which are typically radial planed, as opposed to electric or gravitational potentials which are typically represented by successive envelopes round a common nucleus.

MAGNETOMOTIVE FORCE.

The simple law of potential applicable to the case of a long current-conveying wire, is that the magnetomotive force in any loop surrounding a steady current of c C. G. S. units is $4 \pi c$. This important quantity, magnetomotive force, is that which produces flux. It is convenient to represent it for brevity by the initials M. M. F. in imitation of the analogous term electromotive force in the voltaic circuit, and its recognized symbol E. M. F.

M. M. F. and flux standing to each other in the relation of cause and effect, one cannot exist without the other. In the great majority of cases with which we are familiar, the flux is subject to a potential such as we have above traced, and in all these cases the M. M. F. between any two points is essentially, and numerically, the difference of potential existing between them. The M. M. F. may be stated as producing the difference of potential, or to be the equivalent of the difference of potential itself; but just as in the voltaic circuit, it is possible to have flux where no system of potentials can exist, and it is advisable to observe that potential differences are only a sub-class of motive force. For example, we have observed that no system of magnetic potentials exists within the substance of the long, straight, current-conveying wire; yet there is flux within it at every point except on the axis itself, and consequently there must be M. M. F., but no such distribution that its space gradient corresponds to the flux.

Outside the wire, the M. M. F. or total P. D. (potential difference) is $4 \pi c$ for one complete circuitation, and since the potential at any point is dependent only on the angle contained between the radial planes through that point and some point of reference, it is clear that the potential varies by $4 \pi c$ for each revolution of 2π, or by $2 c$ per radian in circular measure, $\left(\frac{4 \pi c}{360}\right.$ per degree of common measure.$\left.\right)$

Let the plane through O B be the plane of reference, θ and r the polar co-ordinates of any point a. Then having P the potential assumed for O B, and P_a the potential at O a, we have:

$$P_a = P - 2 c \theta.$$

Again, to find the flux intensity at a we have only to differentiate the potential there in the direction along the path of flow, or tangential to the circle, thus:

$$B_a = -\frac{d P_a}{d s} = -\frac{d}{d s}(P - 2 c \theta) = -\frac{d}{d \theta}(P - 2 c \theta) . \frac{d \theta}{d s}.$$

Also, $\theta = \frac{s}{r} \therefore \frac{d \theta}{d s} = \frac{1}{r}$, while P is constant and

$$B_a = \frac{2 c}{r}.$$

From this it follows that the C. G. S. flux at any point near a long straight wire carrying a current is equal to the C. G. S. current strength divided by half the distance from the axis of the wire in centimetres, and is directed tangentially to a circle drawn through the point concentrically with the wire, in the normal plane.

As a practical application of this result, we can readily determine the deviating influence of such a current-conveying conductor, on a small magnet suspended in its vicinity. Suppose the needle suspended horizontally about its axis directly over and 40 centimetres away from a very long horizontal wire lying in the magnetic meridian, and carrying a current of 20 amperes (2 C. G. S. units), the earth's horizontal component of flux being 0.2 C. G. S.

The flux intensity due to the current at the position occupied by the needle will be $\frac{2 c}{r} = \frac{2 \times 2}{40} = 0.1$. Each pole of the needle will therefore be acted upon by two horizontal component fluxes, one along the meridian plane due to the earth's M. M. F., and $= 0.2$, the other at right angles to the meridian plane, due to the M. M. F. of current, and $= 0.1$.

The resultant of these rectangular components will be $\sqrt{0.04 + 0.01} = \sqrt{0.05} = 0.2236$ and its direction will make an angle $\tan^{-1} \frac{0.1}{0.2} = \tan^{-1} 0.5 = 26^\circ . 34'$ with the magnetic meridian. The needle will assume the local direction of resultant flux, and deflect through this angle on the establishment of the current. The direction of deviation will, of course, depend on the direction of the current in the wire, but the deviation of the north pole will always be related to the direction of the current in the same manner that the rotation of a nut is related to its retreat or advance upon an ordinary right-handed screw.

GUTTALINE.

A NEW preparation for the purpose of replacing india-rubber and gutta-percha has been brought out and protected by MM. Worms and Zwierchowski. To a quantity of Manila gum tempered with benzine is added 5 per cent. of Auvergne bitumen, also mixed with benzine. These are thoroughly mixed together by mechanical means and by hand. By adding 5 per cent. of rosin oil and allowing 48 to 86 hours to pass between each treatment, a product is obtained having all the suppleness, elasticity, solidity and durability of the best india-rubbers. If the product is too fluid, the addition of 4 per cent. of sulphur dissolved by means of bisulphide of carbon will remedy this. The addition of 5 per cent. of india-rubber to this mixture makes an excellent compound for certain purposes. The vulcanization of this product can be carried out in the usual way.

ELECTRICAL COOKING.

INTERESTING and instructive lectures, says *Industries*, are held in connection with various electrical exhibits at the Crystal Palace. Mr. H. J. Dowsing delivered one on the domestic applications of electricity before a somewhat critical audience recently, in which electric ventilation, electric knife cleaning, electric hat and linen ironing, and electric cooking were shown in practical work. In fact, everything domestic that needs heat, light or power is to be done electrically. The electrical cookery is especially clean and dainty, and is well worthy of inspection.

POINTS ON RAILWAY POWER STATIONS.

BY

Wm Lee Church

[illegible]OT the least marvelous feature of the extraordinary development of electric railway interests, has been the comparative freedom from disastrous mistakes. Looked at from the other side, this is equivalent to saying that street railways have paid from the start. As much as this can hardly be said for any other parallel industry. Electric lighting was notoriously prolific of financial disappointment for many years, and it is only at a comparatively recent date that capitalists have come to understand that electric lighting can profitably be conducted only under the direction of the highest grade of engineering supplemented by close business management. It is undoubtedly true that the experience gained in the exploiting of electric lighting has been turned to account in the development of electric railways, but the marvel still remains that an industry which three years ago was almost unknown, except as a curiosity, should in this short time have attained to a first magnitude among business enterprises, with so little to regret in the way of failure. It is also undoubtedly true, that there are many roads now doing well, which under still better engineering might have done better—and indeed very notably better. Nevertheless, the disposition to let well enough alone, serves as an equalizer of what might otherwise be at least a relative disappointment.

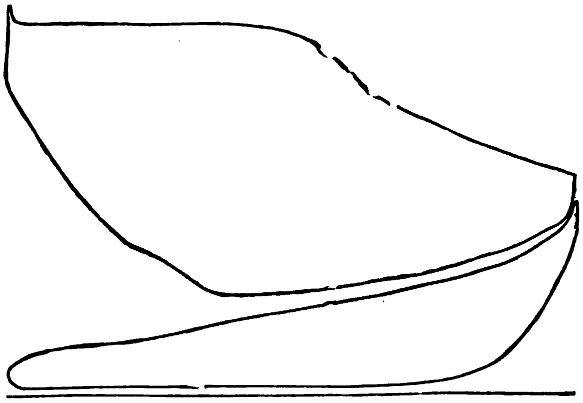

FIG. 1.

It is a narrow mind which will attempt to keep to itself special knowledge on subjects of this nature. The broad education of the public leads through a general increase of intelligence to a greater certainty of success, which, in its turn, redounds directly to the interest of the educator. The writer and his associates have, in the course of events, accumulated certain well-grounded experiences which are of interest to the promoters of electric railways. It is our purpose to give the benefit of this experience as freely as may be to the railway interests at large, and random articles may be expected in the columns of this journal from time to time accordingly.

The subject under consideration at this moment is that of the relative capacity of engines, generators and boilers in the power station. To go at once to the root of the matter, we refer to the diagram which is the chart of ampere readings from a single generator operating an extension line to a cable railway. The generator in question was of the direct coupled, multipolar, slow speed type, popularly known as the "Kodak." Readings were taken at intervals of 15 seconds, and the portion selected for the diagram covers a total time of 21 minutes. While resembling in general appearance similar charts taken from all railway service, it is noticeable that at several points the load entirely vanished for a few seconds. This was due to the fact that but few cars were operated on this extension and the grades were numerous and abrupt in both directions. It would frequently occur that for an instant all cars would be on a down grade, and the circuits entirely open. The most abrupt change is seen to be from 10 amperes to 135 amperes in less than one-half minute. At 4:59 p. m. there was a change from 130 amperes to no load, occurring in three-quarters of a minute. It is worth remarking that under this violent treatment, which is never ceasing throughout the day, the change of speed of the engine and coupled generator could not be noted by any ordinary speed counter. So closely has instantaneous and complete governing been secured through the use of inertia as the governing force, that variation of speed can no longer be detected by the speed indicator and expressed in variations per minute, but must be searched for by the chronograph and expressed in variations per stroke.

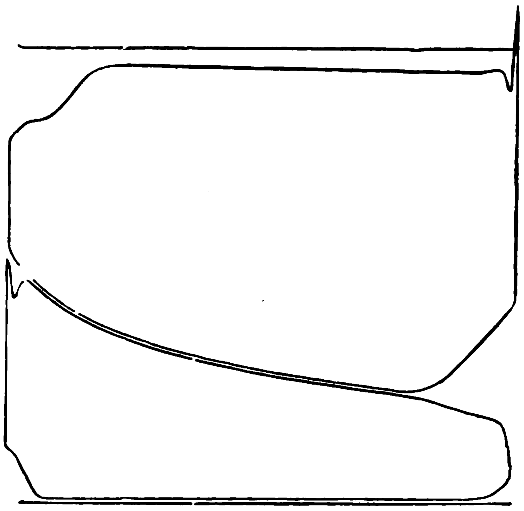

FIG. 2.

Passing to the question of capacity, we will take the generator as the unit of measure. This is moreover the natural unit since the expression for the capacity of a station is in terms of electrical horse powers at the ammeter. In dealing with a problem of this kind, there has sufficient data been accumulated to insure a very close estimate of the nominal amount of generating capacity required to operate a certain number of cars, taking always into account in each special case the grades and curves of the road, nature of the special holiday service, frequency of

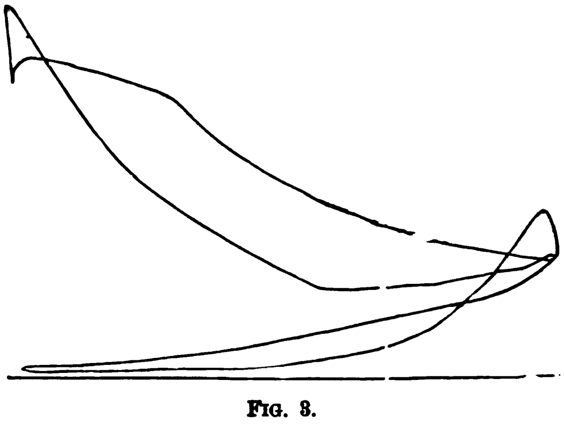

FIG. 3.

stops and other governing considerations. In some respects it would be better if the maximum demand upon the generator could be known, as indicated by the summit of the curve occurring at about 5:06 p. m. on the diagram; but this is, in the nature of the case, hard to determine.

But to facilitate our discussion of the problem, assume that the maximum capacity were known to be 175 amperes, as indicated. We would then locate our nominal generating capacity at some point as indicated by the heavy black line. The reason of this is found in the fact, that an electric generator can stand an overload, or even an excessive overload, provided it does not have to stand it long. The question is simply one of heat. The overload here was seen to continue for only about one minute, during which time the generator could carry it with ease with no perceptible rise of temperature to injure the insulation. If this load had been continuous for an hour or so, as would occur in an electric lighting station, a much higher relative generating capacity would be required, approximating the maximum load.

In this connection it is well to point out that, generally speaking, a long, easy grade is more trying on the generating plant and will call for a greater capacity of the generator, than a short heavy grade. I recall an instance where the lowest point of the road was on a bridge crossing a stream, on either side of which was an abrupt heavy grade for not over 100 yards. Beyond this, the grades were comparatively easy, but persistently up-hill. Although not obvious to the untrained eye, it was the long continued and easy grade which governed the proportioning of the power, and the short grades at the bridge were practically ignored.

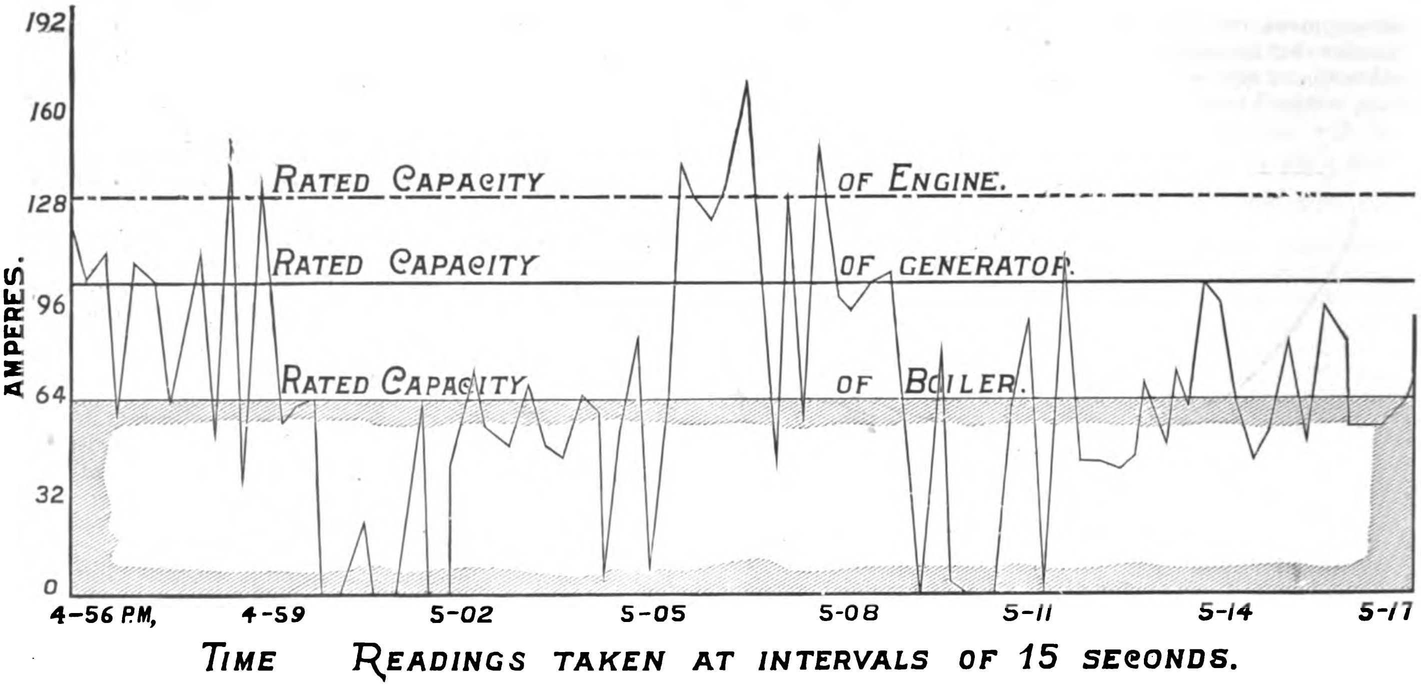

FIG. 4.—AMPERE READINGS FROM A SINGLE ELECTRIC RAILWAY GENERATOR.

Having settled upon the capacity of the generator and located it in the relative position indicated, we next determine the capacity of the connected engine. I am speaking, of course, in this, of power stations in which the generation is in independent units, and I shall undertake to show in subsequent articles what is rapidly becoming established, namely, that a railway station can only reach its minimum capitalization and maximum earning capacity when so designed.

Now, an engine has no such capacity for excessive overload as a generator. In other words, the element of time does not enter into the engine problem, but it becomes a question of how much the engine can actually lift by main strength without taking the governor to an extreme which shall slow down the speed. In general terms, the engine should not be called upon to perform, even for a short time, more than 20 per cent., or possibly 25 per cent., above its rating; we are assuming, of course, that it is honestly rated.

I show herewith three indicator diagrams from a non-condensing compound engine, of which the intermediate size, Fig. 1, indicates about the fair load at which the engine would be rated, and the largest, Fig. 2, shows the ability of such an engine to meet excessive overload. I do not know that I have ever seen this latter card equaled, since it represents 33 per cent. overload with an absolutely perfect distribution of steam, and no loss between cylinders. The smallest card, Fig. 3, indicates the load which might occur a few seconds later in the performance of railway work.

The engine capacity, therefore, must be sized up with reference to the maximum load, and would have a nominal rating greater than that of the generator, being located at some point as indicated by the broken line. It will, of course, be understood that the ability of the valve motion of the engine to take care of momentary overload beyond its own rating is further supplemented by the value of the fly-wheel, although recent practice in connection with the inertia governor, tends towards exacting less from the fly-wheel and more from the steam distribution. The final selection of the engine as to size will depend in every case upon the local conditions of steam pressure as the principal factor.

I will point out further that the capacity of the engine should be determined without reference to condensation. In the vast majority of cases water for condensation cannot be had, and compound engines of this type are now so designed as to yield an almost uniform fuel duty when non-condensing over the full ranges of load that occur in railway service. But even where it is determined to condense, the condenser should still be treated simply as an adjunct of economy, and not as a part of the power. This is for the obvious reason that a condenser may become choked or disabled, or leaky, and the vacuum may be poor, or lost entirely under sudden fluctuations. The engine must by all means be of adequate capacity to walk away with the load without leaning upon its comparatively uncertain assistant. This caution is, by the way, no discredit to condensers, but is simply a necessary consequence of the conditions under which condensers are generally called upon to operate.

We next reach the boiler capacity. It will be obvious that the boiler has to deal only with the *average* of the total load. In the diagram this average is indicated by the shaded rectangle, and is somewhat startling as compared with the apparent power of the remainder of the plant. In this particular, electric railways exactly resemble rolling-mills, saw-mills, and kindred industries, where the load is spasmodic, with variations lasting but a few seconds, or, at most, but a few minutes. The stored heat in the water of a boiler is enormous in quantity, and responds instantly to a release of pressure. That is to say, the boiler is an immense reservoir of power as to volume, and provided the drain upon it is not continued too long, it will stand exactions far beyond its nominal capacity, and without any effect whatever upon the firing. In the earlier stations which we constructed, we did not give sufficient consideration to this fact, which ought to have been obvious. The result was a boiler plant approximately equal to the engine capacity, a large portion of which plant is, perforce, lying idle and unproductive of anything but interest account. Having first encountered this relation as a matter of experience, it did not take long to arrive at the reasons lying back of it, and as a consequence all our stations are now designed with some such proportion of boiler power as is indicated on the diagram.

There has been altogether too much "rule of thumb" in electric railway work, as in other departments of engineering. For instance, "rule of thumb" says, in ordinary mill work, that there should be 20 per cent. more capacity of boiler than of engine. This rule applied without judgment to electric railways, and without considering the characteristics of the engine used, would result in doubling the necessary investment in boilers and in the buildings to accommodate them.

In this discussion I would not be for a moment understood as advocating cheese-paring in the matter of any of the items comprising the generating unit. I am referring only to a question of relative proportion. The intelligent engineer who knows the results of his work are to be interpreted in the light of dollars and cents earned, will follow the excellent advice: "While you are a gittin', git a plenty." The relative proportions, however, will be found very closely as indicated. We would introduce the caution that a relay boiler should always exist in every station. A large station will carry a relay unit throughout, but even a moderate station should show one relay boiler and a relay feed pump. The engine and dynamo can be fairly trusted to take care of themselves, since any ordinary repairing can be quickly made between running hours. Not so with the boiler, which is liable to occasional repairing or cleaning that will throw it out of service for one or more days, and this is not thinkable in connection with street railways.

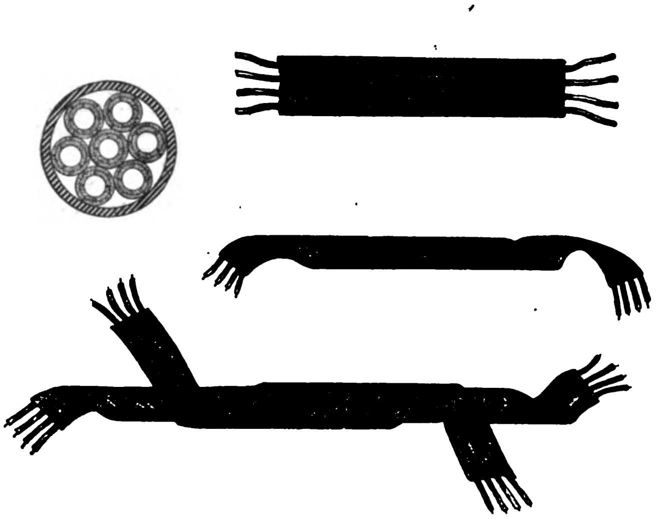
The actual size of the boiler will, of course, depend upon the type of engine used. With the compound engine above described, making such diagrams as are here shown, and running non-condensing, an allowance of 30 lbs. of water actually evaporated for each indicated horse power will give abundant margin for all contingencies. It must be borne in mind that the duty under an average uniform load is a very different thing from the duty under a variable load represented by the average. Under the uniform load, 23 lbs. of water would be the actual engine performance, and the boiler could be proportioned with reference to this figure. Under the violent fluctuations of railway service, the average duty of the engine will rise to about 28 lbs., and if the maximum average load is taken, and the boiler proportioned for 30 lbs., there will be a sufficient margin.

These remarks apply only to the particular type of engine under discussion, as other compound engines not possessing the feature which secures uniformity of duty, will range up to at least 45 lbs. under light loads, and often to 60 lbs., and represent an average duty not better than 35 to 40 lbs. The same is true of every form of non-compounded engine, whether high speed or low speed, both of which show a tremendous falling back of fuel duty under variable load. But in the language of Rudyard Kipling "That is another story," and is worth another article.

THE SAWYER TELEPHONE CABLE.

In order to produce a cable for telegraph and telephone work having low inductive capacity and high insulation, and which, at the same time should be light, flexible and inexpensive, Mr. William H Sawyer, of the American Electrical Works, Providence, R. I., has recently devised the arrangement shown in the accompanying illustration.

In Mr. Sawyer's cable a number of insulated conductors *a*, usually four in number, are braided or woven at regular distances apart with some fibrous material into a continuous flat ribbon, which is then twisted or wound into a spiral tube A, leaving a central air-space. The conductors are so woven with the fibrous material as to form an open-mesh work between the wires, and when the ribbon is twisted into a helical form the wires are all approximately equidistant, thus securing the lowest inductive capacity between them. Upon the spiral tube thus formed is wound a second ribbon, similar to the first, but wound in a reverse direction; thus securing the greatest separation of conductors within the least possible space.



SAWYER TELEPHONE CABLE.

In forming the complete cable a number of sections thus constructed are grouped together and inclosed in a lead sheath, or a series of successive ribbons carrying the braided wires may be wound upon the spiral tube A until the cable is built up to the desired diameter and then inclosed in a lead sheath, each ribbon being wound in a reverse direction to that of the underlying section.

A DASTARDLY ACT.

During the little excursion given by the Ford-Washburn Storelectro Company to the members of the Toronto city government on their storage battery car last week, there was a singular episode, to state it mildly. Towards the end of the trip it was discovered that some one had joined the wires on the rear end, used for connecting the battery with the meters, in such a way as to short-circuit the whole battery! This occurred when Mr. Washburn and his assistant were in front driving the car. The Washburn battery, however, was uninjured. The evident object of this dastardly act was to hamper the running of the car, but it had no appreciable effect upon it, and was therefore an unwitting advertisement in its favor of the highest value.

THE
ELECTRICAL ENGINEER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, APRIL 27, 1892. No. 208.

> ***Every student is surprised to find how very little is the share of new truth which even the greatest genius has added to the previous stock.—Josiah Parsons Cooke.***

REMOVAL NOTICE.

THE ELECTRICAL ENGINEER will remove its office, April 27, to the fine new *Mail and Express* building, Broadway and Fulton Street.

The address will be

203 Broadway.

The new quarters are not only more spacious and commodious than the rooms occupied during the past two years, but are better adapted in location and in facilities for conducting business and receiving visitors. The site is in close proximity to the Post Office and the Astor House, and but a door from the Western Union headquarters.

203 Broadway.

STORAGE BATTERIES IN CENTRAL STATION WORK.

THE rush into alternating current work in this country has been so great that many electrical engineers have lost sight of the fact that the use of such currents is only one way of distributing electrical energy for light, and not the one only way. This headlong adoption of a new thing is characteristically American, and so often leads us forward to better things that it may be forgiven when it sometimes blinds us to the advantages still to be found in other methods suffering from neglect. In this instance, if we may judge by reports reaching us from across the Atlantic, no small injustice has been done the storage battery in the distribution of electricity. Indeed should these reports be but half true, the storage battery has entered upon a period of rehabilitation very much like that of the prodigal who wasted his substance and other people's in riotous living and then settled down to hard work and fat veal. That use should be made of the battery in central stations is not surprising; on the contrary, the wonder is that to-day in this country, so far as we are aware, not a single central station employs storage cells as an auxiliary in the supply of current.

In a recent work on continental central stations, based upon a German volume of official reports already reviewed in these pages, Mr. Killingworth Hedges gives a list of stations in which batteries are a valuable adjunct. Most of the plants are small; but some of them are of quite respectable size. They run as follows: Barmen, 5,000 lamps of 16 c. p.; Hanover, 30,000; Düsseldorüf, 20,000; Dessau, 2,500; Rheims, 540, Berlin, 800; Bad Kösen, 600; Gevelsberg, 2,000; Bamberg, 2,700; Darmstadt, 5,800; Paris, 19,500; Gablonz, 1,500; Konigsberg, 1,600; Blankenburg, 1,000; Berlin (Hospital) 2,000; Vienna, 10,000. To this list might be added, we believe, Salzburg, Lyons, Toulon, Montpellier, Mulhausen, Stockholm. Sundsvall, Munchen-Schwabing, Varese, Susa, Bremen, Breslau and Stettin, although few details are given with regard to these; while it appears that batteries are to be added to the Hamburg central station which operates 12,000 lights; Wildbad-Gastein, 1,200; Elberfeld, 14,000; Arco, 2,500. It is not to be understood from this list that the equipment of batteries is in any instance equal to the number of lamps named; but in several cases the figures are large. Barmen, it seems, has four double sets of batteries, 68 cells each, and is now going to erect five sub-stations which will be charged during the day by the main central station. We do not think this sub-station plan has had any trial here since that of half a dozen years ago at Cheyenne, Wyo., and at Germantown, Pa. At Hanover, the accumulators are placed on four floors, each battery consisting of 136 cells of 1,320 ampere hour capacity, and a discharge of 396 amperes. The Düsseldorf plant is already running three battery sub-stations; the largest has two batteries of 140 cells, each with a discharge of 483 amperes, while the other two with an equal number of smaller cells discharge 248 amperes. An interesting feature of the Dessau installation is the employment of gas engines as primary power. It is stated that the addition of accumulators of 1,700 ampere hour capacity to this plant increased the investment 15 per cent, and raised the output

38 per cent. The present batteries have been in use uninterruptedly for nearly two years without attention, so it is asserted, and more than once have been called upon for an output 20 to 25 per cent. above the normal.

Evidently we must deal with a condition rather than a theory. If all these various plants in Europe, with different batteries and generators, find it profitable to operate in this way, surely there is opportunity for similar methods in America. We have been informed that the tendency abroad is in the direction of using much larger cells than anything yet known here, and the idea strikes us as eminently shrewd and feasible. Why not try it here?

NON-ARCING METALS.

Now that the broad lines of electrical engineering are fairly well established and the profession has attracted to it many young men well grounded in theory, we find frequent instances of extended research and investigation with the object of improving the details of existing apparatus. Prominent among these studies, of late, has been that of the lightning arrester, new examples of which, based on a variety of principles, have from time to time been described in our columns. One of the most original communications on this subject was, without doubt, the recent Institute paper of Mr. A. J. Wurts, in which he demonstrated the peculiar non-arcing properties of certain metals which thus fitted them specially as materials for the construction of terminals between which arcing is likely to occur. Mr. Wurts' original theory explained the action observed, by the assumption of a non-conducting oxide formed by the arc, while in a recent issue Mr. R. G. Fessenden, as the result of experiment, inclined to the pure metallic vapor theory. In this issue Mr. Wurts returns to the subject, bringing to his assistance that powerful aid to modern research, photography, and showing in a striking manner the great reduction in the violence of the arc as encountered with the usual terminals. These photographs are also of no little interest as bearing upon the fact, now pointed out by Mr. Wurts, that all of the non-arcing metals thus far investigated are diamagnetic, a circumstance which throws some light on the repulsive action in the arcs shown in the photographs. The reduction of the arc with the reduction of the air-gap might be explained on the assumption that the reduced gap is jumped by a lower accumulated potential and hence one less violent in its action.

ELEMENTARY ELECTRO-DYNAMICS.

We began in our last issue the publication of a series of articles on "The Theoretical Elements of Electro-Dynamic Machinery," from the pen of Mr. A. E. Kennelly, to which we would draw special attention on account of the method of treatment adopted by the author. Notwithstanding the works already extant, we agree with Mr. Kennelly that there is room for a particular line of technical literature bearing upon electromagnetic machinery; not the purely scientific treatment of Maxwell, and his followers, nor the path of practical description of machinery, both these aspects of the very wide subject having already been well treated. We refer to what might be called applied theory. That is to say, there would be fewer badly designed motors and abortive transformers, if the fundamental principles of their theory were more generally grasped. There are many good motors and transformers, but their excellences are often caviare to a multitude of their operators for similar reasons. The theory of their electrical behavior is often hidden under a pyramid of symbols, and it seems frequently that the purposes of mathematics would be better served by a little less brevity and a little more verbiage, in specific applications to the work of those who are not long trained to their manipulation. The series of articles that would reach the actual workers must be quantitative essentially in their treatment, and must therefore be mathematical, but the reasoning can be brought within the grasp of all students of average powers, by proper treatment. We feel convinced that a great demand exists for such a course of literature. For, have we not all often pored long over some mystic statement in well-known tomes that a turn of the wrist would have made so easy? Nature is always easy, and difficulties arise from the superposition of many simplicities that mutually conceal.

Mr. Kennelly will lead up from the theory of electromagnetism, so far as it is practically essential, to the principles of electrical design—not mechanical design—in the leading forms of simple magnetic machinery.

POINTS ON RAILWAY POWER STATIONS.

Considering the comparatively short time during which electric railways have come into operation, it must, indeed, be a subject for congratulation that electric railways are paying and paying well, even those roads that were among the first to take up this mode of traction. While admitting this, Mr. Wm. Lee Church very truly remarks that, notwithstanding the success in electric railroading, improved methods of power station construction and equipments might well be adopted in many cases. He proceeds to demonstrate, in this issue, just in what way the highest economy can be obtained. He has taken up the important question of the proportions between the generator, the steam engine and the boiler capacity, a subject which will be admitted to be of the highest importance. Mr. Church bases his arguments on the premises that both the boiler and the electric generator are capable of carrying a considerable overload with safety for short intervals of time, while the engine on the other hand is less able to stand overloading in the same way. These are points which we have not seen brought out in this way before, and they deserve the closest attention and scrutiny of all electric railway managers.

Mechanical Strength of Dynamos and Motors.

In the series of articles on the practical management of dynamos and motors, Messrs. Crocker and Wheeler discuss this week a question which is too often lost sight of but which is entitled to the most serious consideration. Mechanical strength, especially in moving parts of the dynamo-electric machinery, is of the highest importance, the more so as these machines are subjected to stresses, as in the case of the armature, which are usually not taken into consideration. While it is desirable to prevent waste of material, it is always well to be on the safe side, and a little extra metal in the right place may avoid much vexatious repairing later on.

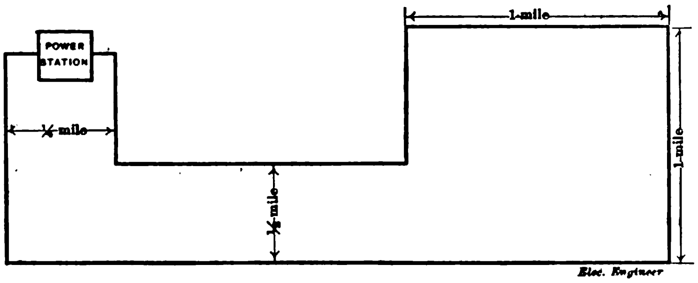
ECONOMY IN ARC LIGHT WIRING.

BY

H. B. Rommel

In taking exception to my discussion of his paper on "Economy in Arc Light Wiring," Mr. Sharpsteen still labors under the delusion that all of our towns in which plants of from 50 to 80 lamps are in operation are necessarily densely populated and have but two or three streets which run parallel to each other, and very close together. Under these favorable circumstances, I admit the value of the proposed system of wiring; but unluckily for the engineers in charge of such construction work, they do not often meet with such a favorable arrangement. It is true that the majority of such towns have but two or three business streets but not often located to advantage.

I give below a sketch of the business streets of one of these towns, where I was called upon to construct an arc circuit for 50 lights. About twenty of these were street lights and the remainder commercials. It was necessary for us to have the line on every street shown, and to loop from one street to the other, in order to keep the commercials (which were about evenly divided) in rotation, we certainly would have consumed at least as much, if not more, wire by Mr. Sharpsteen's method than by running two complete circuits, and a great many more poles, which it would be necessary to place on side streets where they would be of no benefit for the use of other wires. It must be remembered that the original cost of poles and setting enters into consideration as a matter of economy, as well as the amount of wire consumed.



A METHOD OF ARC LIGHT WIRING.

I by no means lose sight of the fact that the line can leave the main street and return several blocks below or above; but it is doubtful if this is advisable, as electric light superintendents are well aware of the fact of the instability of commercial arc lights in our smaller towns; these lamps often being in service but several months, when they are removed to another customer. If the plan in question is followed, the poles and wire constituting the loop for this lamp are a dead loss, unless a consumer be found near the same place, and the advantage of having the line the entire length of these streets, when a possible future customer can be immediately given service, is easily seen. The continual planting of poles and stringing of loops under the proposed plan is by no means inexpensive, and will often amount to more than the possible saving in wire. This system of wiring certainly has its value in some instances, but it should by no means be considered as a standard for all of our smaller towns.

Mr. Sharpsteen requests that I mention the arc lamp of which I said the excess current passing through the magnet coils after the point of cut-out has been reached was detrimental to the coils and adjustment of the lamp. The lamp in question was the Thomson-Houston, which is no doubt more extensively used than any other in this country to-day. Any person familiar with this lamp will appreciate the difficulty experienced by allowing the lamp to cut itself out as mentioned; and will see the necessity of a short-circuiting switch, or some similar device, for the safety and good adjustment of their lamps, which, in other words, means economy and satisfactory service.

METHODS OF ELECTRICALLY CONTROLLING STREET CAR MOTORS.[1]

BY H. F. PARSHALL.

While in many respects the controlling apparatus for street car motors and the general requirements of the same do not differ greatly from some other cases, there are some features that demand the closest attention if the car is to be handled either efficiently or comfortably so far as the passengers are concerned. While the number of methods proposed and tried in times past has been great, at the present time there seems to be sufficient agreement between the principal designers and sufficient data at hand to warrant the writing of a fairly comprehensive paper on the subject.

The problem of controlling the motors is probably the most difficult one in the whole range of street car work, and in no small degree determines the electrical design of the motors, or, to be more specific, to start a car under any given conditions of track a certain torque is required. Beyond a certain limit, fixed largely by the convenience of passengers, this torque cannot be exceeded. The smaller the current with which the motor is able to develop this torque, the smaller the rheostat or other starting devices may be and the more efficient the car equipment. Should the motor, therefore, be incapable of developing a comparatively powerful torque per ampere, the amount of energy dissipated either in the magnetic windings, armature windings, or rheostat becomes excessive, the results being the more or less rapid deterioration of these parts.

It may not be out of order just here to discuss the design of the motor with reference to getting this torque most efficiently. The average h. p. exerted by a street car motor at the car wheel probably does not exceed 20 per cent. of the maximum it is expected to do in starting the car under the various conditions encountered. Now to get the highest efficiency from a motor run under these conditions, it is necessary to get the highest possible efficiency at that h. p. at which the greatest amount of work is to be done, and inasmuch as the loss in the conductors for this average h. p. is necessarily low (otherwise the motors would burn out in doing the maximum work to which they are subjected), the question does not resolve itself into how to get the least possible motor resistance of armature and magnets, but rather, how to minimize the constant loss of hysteresis, eddy currents and friction. While all of these losses vary somewhat with the speed in series-wound motors, the variation of these losses is not great, since for an increased speed there is in general a diminished intensity of magnetization and pressure. To render these losses a minimum, and at the same time to get the requisite torque to handle the car efficiently, there is but one solution, that is, to put the maximum number of turns on the armature compatible with good running as to heating and sparking.

While the truth of these statements may be more or less apparent to all when stated in plain terms, but little attention was paid to this matter in the earlier motors designed. The numerous measurements made, however, have so uniformly been in favor of motors with comparatively a large number of conductors on the armatures, that the importance of this matter is now pretty generally understood. This agreement as to the general design of motors has in no small way been influential in bringing electricians into agreement as to how the motor should be controlled, since with an armature of a comparatively large number of turns, less turns are required in the field magnets to produce a given torque with a given number of amperes. The function of the magnets, therefore, has become of less importance. It is always, however, to be borne in mind that, other things being equal, the motor with the greatest number of turns in the magnets will develop the greatest torque for small currents. With a given E. M. F. acting on the armature circuit, and a given torque developed by the armature per ampere, it does not matter, so far as efficiency is concerned, whether the difference in E. M. F. at the armature terminals and the line is due to drop in external resistance, or to drop in the magnets. This point determines once for all, that motors with commutated fields are not necessarily more efficient than other motors.

The particular advantages of the commutated field method are, that with a limited number of pounds of copper, or in the case of street car motors, with the limited space available for field magnet windings, it is possible to adjust the magnetizing force of the field coils so that the rate of doing work of the motors may be made to correspond with the rate this work is required by the car for the various speeds and conditions of track. This adjustment may be made for any size of motor with any required degree of precision by varying the number of magnetic coils. To increase the range of precision it is only necessary to increase the number of coils. In practice it has been found that this number could not be very great, otherwise the car wiring becomes too complicated and too expensive. This same holds true of the controlling switch. Three magnet coils or sets of magnet coils seem to be the practical limit, since there is a general agreement between street railway managers that the present number of magnet connections (6) should not be increased, and even with this number there is occasional trouble with broken wires or terminals. With a 15 h. p. motor it is possible with three sets of coils to run under most conditions met with in practice without employing external resistance. It is occasionally necessary, however, when the car is to be run at two or three miles an hour, to make use of the resistance coil that is ordinarily used only when starting. With 25 h. p. motors it is necessary, with three sets of magnet windings, to make use of this resistance coil very considerably in ordinary practice, since without this it is not possible to get a speed of less than one-third the maximum speed of the car, which is generally taken to be about 18 miles an hour.

---

EFFICIENCY OF STREET CAR MOTOR NO. 6.

Brake H. P.	Efficiency.	Speed.	Remarks.	Res.
14.3	87 per cent.	1110	3 coils in parallel........	0.8
11.8	87 "	1174	3 " "	.8
11.4	86 "	1184	2 " "	1.4
9	84 "	1309	2 " "	1.4
8.25	82 "	955	2 in parallel, 1 in series..	3.24
6.35	79 "	1040	2 " 1 " ..	3.24
4.9	72 "	1070	2 coils in series..........	4.86
3.9	70 "	1014	3 " "	7.42

The range of speeds without the use of a rheostat is determined by the limit to which it is safe to heat the magnets. The temperature of the magnets should not in any case exceed 65° C. This would put the increase of temperature at about 30° C. This increase corresponds to an average loss in the magnets of about 0.3 of a watt per square inch of radiating surface. For the few seconds generally taken to start the car the loss may be as high as two watts per square inch without dangerous heating. Experience, however, has demonstrated that to exceed this limit, even for very short periods, there is considerable risk. Having the maximum number of watts that may be dissipated in the magnets, the series resistance of same may be calculated from the properties of the motor on the supposition that each ampere taken by the motor produces a certain number of pounds pull at the periphery of the car wheel. In a well-designed motor with commutated fields it is easy to get from 35 to 40 pounds pull at the periphery of a 30″ car wheel with the coils in the series position. These coils are either wound side by side, or one on top of the other, according to the necessities of the case as determined by the general design of the motor. Experience has shown the advisability of winding these coils in independent spools whenever the general design will permit, since in case of trouble it is cheaper and easier to replace the damaged coil, and there is less liability of crosses between the coils. As an example of a design, that has been found to give general satisfaction in practice, I give the figures in the table from a series of tests made on a Sprague No. 6, S. C. Motor, the magnetic data of which has already been published by myself.[1]

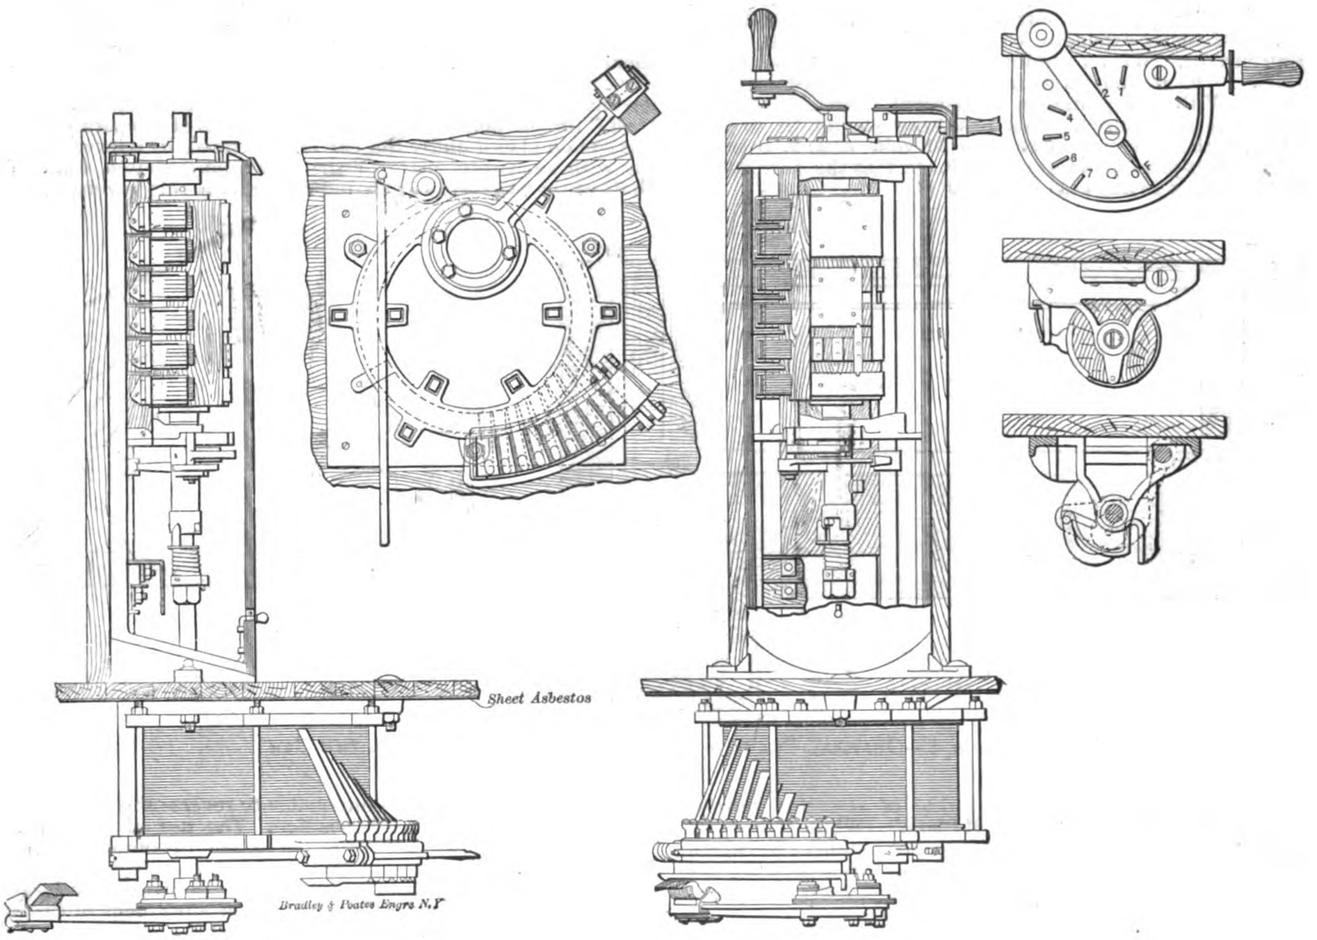

FIG. 1.—PLATFORM SWITCH ARRANGED FOR SERIES-PARALLEL SYSTEM OF CONTROL.

It is to be noted especially that it is possible to get an approximately constant speed with a wide range of loads, and yet have the energy dissipated in the magnets remain approximately constant, and that it is possible to get a torque corresponding very approximately over a wide range, to that required to propel a car under conditions met with. This is the solution of the question, How to get the highest efficiency. For instance, suppose a car is to be run between two points in a given space of time, and this is not an unfrequent requirement, and that the magnet windings of the motor are such that either the car runs the distance in too short a time or in too long a time; it will be necessary then to accelerate the car for a time beyond the limit required, then to allow it to slow down, then to accelerate it again, or go through some such cycle of operations to get the required results. More power will be required with such windings than when such a torque can be had at the motor, that will produce the required speed by an approximately uniform acceleration. To get the same results given above for the No. 6 motor, with the magnet coils arranged in loops instead of separate coils would require upwards of three times as many pounds of copper as was used in the present case (110 lbs.) This motor was designed to give a maximum car speed under ordinary conditions of from 12 to 15 miles an hour. At present it is thought advisable to have a maximum car speed of from 18 to 20 miles an hour,[1] since numerous measurements have shown the economy of running street cars at as high a speed as the conditions of track, etc., will permit. In a series of measurements made by myself, it was found that the watt hours per car mile decreased very considerably with the speed of the car up to 30 miles an hour. To get this high speed, (20 miles per hour) it has been found necessary to vary the proportions of the magnet coils from that given in the above for the No. 6 motor. Thus for a single-reduction 15 h. p. motor the resistance of the last coil to be turned from series to parallel is only 15 per cent. of the total resistance of the magnets, and the turns of this coil only 20 per cent of the turns in the other two coils. The reason for putting this low resistance coil inside, is to get the greatest number of turns when the coils are all in series and the least resistance when the coils are all in parallel. Further, under ordinary conditions this coil has the least expenditure of energy in it, and the least radiating surface. With a winding of this proportion, it is necessary with 15 h. p. motors to use an external resistance of 6 or 8 ohms. With 25 h. p. motors an external resistance of from 10 to 12 ohms is required. This resistance should be so subdivided that there is not more than 20 volts E. M. F. between adjacent contact-pieces, and so proportioned that the increase of temperature is not in any case above 150° C.

---

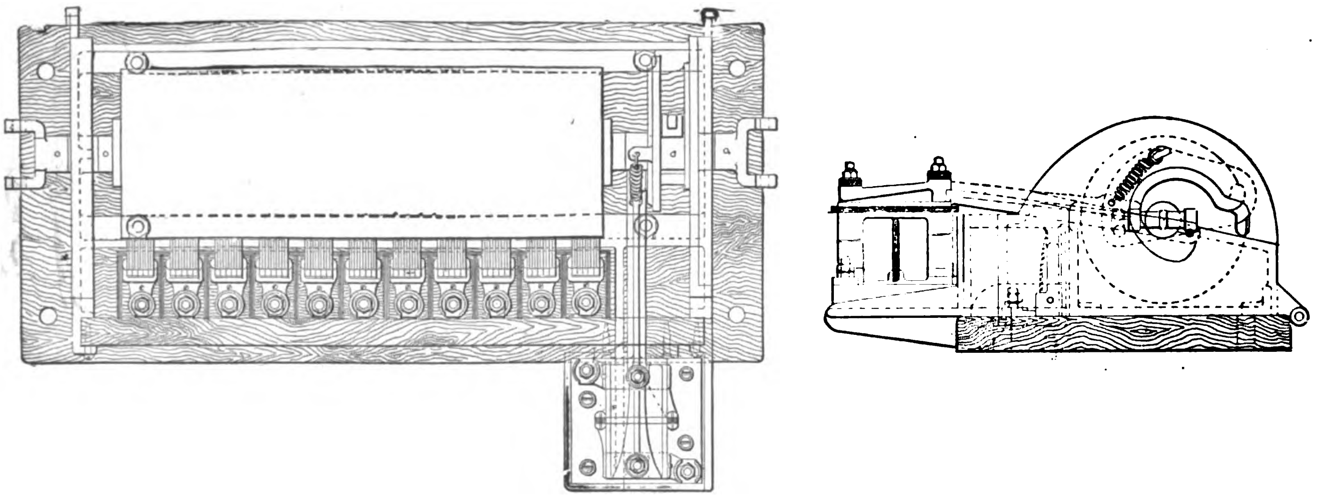

FIGS. 3 AND 4.—GENERAL PLANS OF SWITCH WHEN PLACED UNDER THE CAR.

A method that is receiving a great deal of attention now is that known as the "Series Parallel Method." While it has not yet been introduced very largely in practice, numerous experiments have indicated the desirability of doing this as soon as some of the troublesome features of the switch have been overcome. The method of operating is as follows:

In starting, a rheostat of from 8 to 20 ohms is used, according to circumstances, in series with the motors, which are in series with each other. After this resistance is thrown out of circuit the magnet coils of one of the motors are short-circuited, a section at a time. To make the start smooth, three or four coils at least are required. The magnet coils being short-circuited, the armature is then short-circuited, and the magnet coils thrown in circuit simultaneously with the armatures being thrown in parallel. It is just at this point where the difficulty with the switch has been encountered, since either the switch has to be operated with great rapidity or the contacts act in perfect unison; otherwise unpleasant results as to short-circuiting occur.

The advantages of the method are that a very wide range of speeds are obtainable at a comparatively high efficiency, and that the energy required to be dissipated by the rheostat is small for the low speeds frequently required in city practice. This lessening the duty of the rheostat is a very important point, since as yet it has been found exceedingly difficult to construct a cheap rheostat that could be placed under the car in the small space available and dissipate so large an amount of energy as is required when the car is to be run for a considerable time at a speed as low as two or three miles an hour. Any method of control that has lessened the energy to be dissipated in the rheostat has in general been considered with favor, since there has been a corresponding diminution of trouble in each case that the energy to be dissipated has been lessened.

Having now given a general discussion of the problem a brief description of some of the apparatus recently devised may prove of interest.

Fig. 1 shows the general design and arrangement of an improved form of platform switch, which combines both the "field commutation" and the "series resistance" methods of starting cars. To start the car, the switch handle is turned from the position marked "off" with a counter-clockwise movement; this movement carries the arm of the rheostat, which is placed under the switch, around and over the contact segments, so that the resistance is gradually cut out of circuit. After the contact arm has been carried around to 135 degrees and all the resistance has been cut out, it is released from the cylinder shaft and left locked in this position. A further movement of the switch handle then affects only the cylinder, and commutates the sectional windings of the field magnets of the motor from series to parallel in the usual way. In stopping the car the field coils are turned from parallel to series, the resistance coil is then again put into circuit and the circuit broken when the contact lever leaves the last segment of the resistance coil, and not, as hitherto, upon the cylinder contacts. The only caution to be observed in stopping is to see that the switch handle shall be turned to the position marked "off," for the motors are reversed by means of a separate reversing switch placed under the car and operated by a lever connecting with a separate shaft in the controlling switch case. The shaft of the platform switch interlocks with this reversing shaft in such a manner that it is impossible to reverse the motors until the cylinder is in the "off" position. The use of this separate controlling switch has been objected to, but to combine both the advantages of the rheostat and commutated fields the switch mechanism becomes too complicated and the switch too large to have the reversing performed by a reverse movement of the controlling switch handle.

The cylinder plates and contacts are made of thick iron stampings, as experience has shown that iron is more durable than brass for this purpose. The burning, due to the formation of arcs, does not have so much effect upon iron as it does upon brass, and there is more certainty of good contact. The contacts on the cylinder consist of a number of stampings arranged in a brass frame, each stamping making an independent spring contact with the switch cylinder. The rheostat employed is built up in a circular form from a large number of flat rings stamped from thin iron sheets. The rings are built up in the form of a cylinder, each ring of iron being separated from the adjacent rings by a ring of mica, except at the point where it makes contact with the ring on the other side of it. Instead, however, of being arranged in a continuous spiral circuit, the coil is divided into a number of parts so arranged that the direction of rotation of the adjacent spirals is reversed, this being done to make the inductance of the coil as small as possible. A coil wound up in a continuous spiral having a mean diameter of 12″ and a radial depth of 1″, 6″ long, and composed of 400 plates, was found to have an inductance of 40 milli-henrys. The coil was then wound up in 12 sections, the direction of each section being reversed, and the inductance in this case was found to be 8.5 milli-henrys. These sections are stamped from different thicknesses of metal, so that those coils which are in circuit the shortest time and have the least current to carry are of highest resistance and least ampere capacity, and those that are liable to be in circuit for some time are thicker and have less resistance and greater ampere capacity. Copper connections are made at different points in the coil, all these connections being brought to a number of small iron contact pieces fitted in a spiral form and arranged so that the switch contact lever can slide over them. The contact pieces are insulated from the frame with sheet mica and from one another with small slate slabs. The rheostat is entirely fireproof and can expel with safety the heat evolved within it under all ordinary conditions. As a point of practical importance it is, however, advisable to place a sheet of metal and a layer of asbestos paper between the rheostat frame and the car floor. This will prevent any danger from fire, either from heating or sparking, should such occur. It is to be noted that the general design of this rheostat is such that those parts having mechanical functions and energy-dissipating functions have been separated as much as possible. Of course the mechanical functions of a rheostat are more or less limited; it is evident, however, this effort is in the right direction. It is with respect to this particular point that the rheostat has a decided advantage over any form of mechanical clutch in starting a car. The clutch, of course, has its advantage in starting quickly bodies that have a great amount of inertia. In ordinary practice, however, the amount of energy dissipated in a clutch is approximately equal to that necessary to dissipate in a rheostat, but the clutch has in addition to its energy-dissipating function, a very exact mechanical function, and these two functions are interdependent on the same wearing parts. For this reason, if no other, clutches have not yet been made to compete favorably with rheostats.

---

[1] All car speeds are quoted for straight and level tracks. These when calculated for a new motor are determined from the speed and horse power curve of the motor, assuming the resistance to be 30 lbs. per ton. The methods of measuring these speeds are in general such, that the probable error is too great to determine the percentage slip of the wheels.

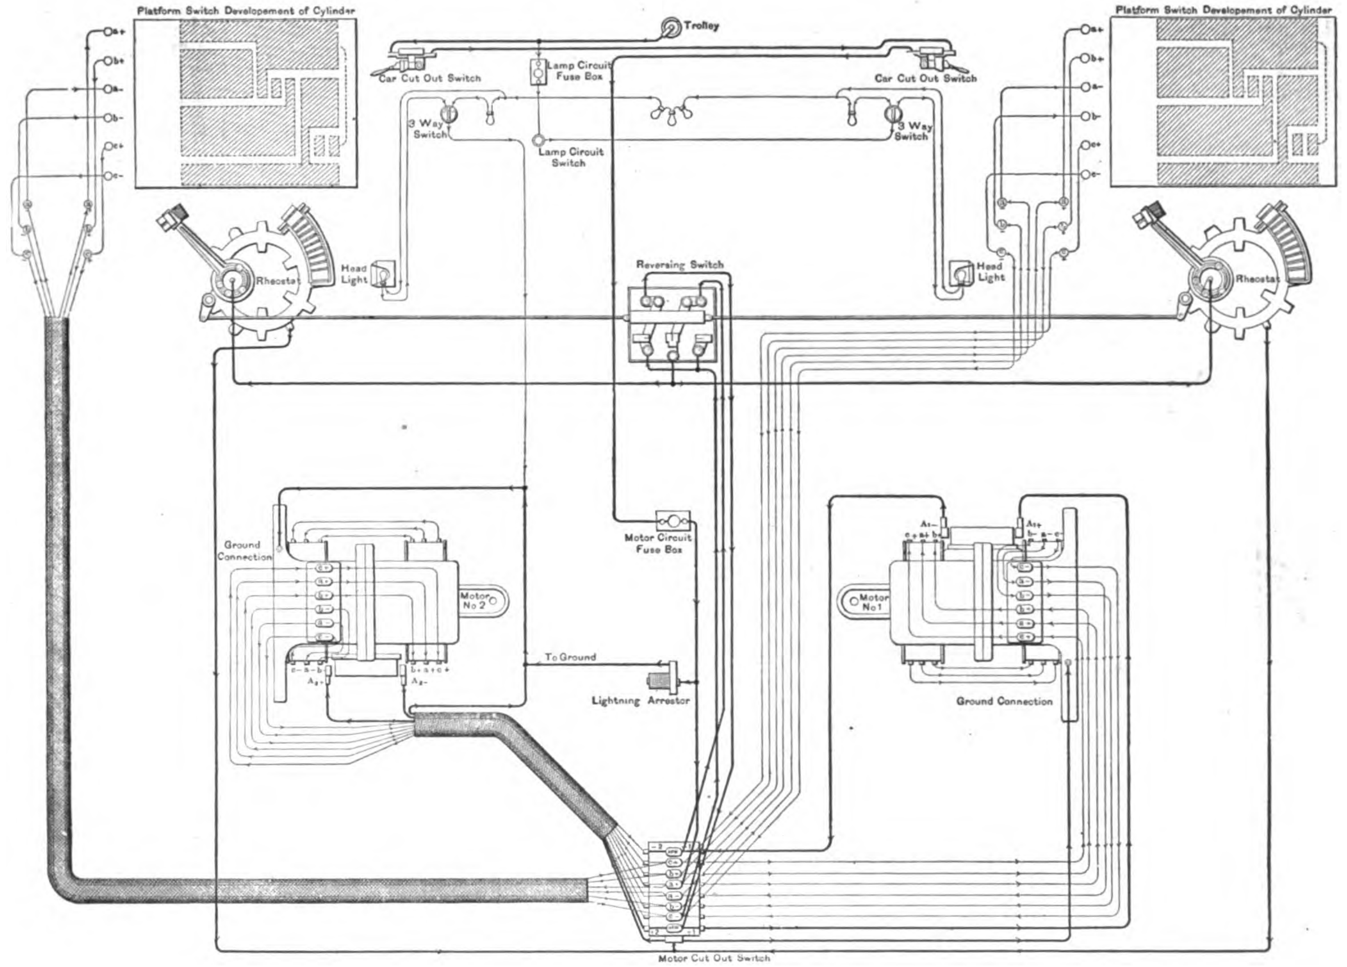

FIG.—DIAGRAM OF CAR CONNECTIONS FOR SERIES–PARALLEL SWITCH.

Fig. 2 gives a diagram of the car connections for this switch. It will be seen that the current from the trolley wire first goes through the field coils and switch cylinder for commutation, then through the armature and reversing switch, and thence through the switch contact lever and resistance coil (in starting) to ground. It will be noticed that by use of the separate reversing switch the armature wires and field wires are each kept separate and distinct from one another. Formerly there was considerable trouble from the breaking of these wires, especially where the wire entered the brass terminals at the various terminal boards. This has been almost entirely obviated by using 49-strand cable wherever wire was subjected to bending.

In some cases the construction at the platform ends is such as to make it inconvenient to place the rheostat used with this form of switch immediately underneath the cylinder. This is the case when certain kinds of draw-bar or step constructions are used. In these cases a modification of the switch arrangements is made so that instead of the rheostat a light frame is placed directly under the cylinder. This frame serves to support the switch shaft, upon which is placed a crank connecting with a bar, which is carried off to the rheostat contact lever. With this arrangement the rheostat can be placed under any convenient part of the car flooring and operated as well as when directly under the platform.

Figs. 3 and 4 show general plans of a car switch designed to be placed under the car and about half way between the motors, when the car construction permits. This design, while open to the criticism that the switch is somewhat inaccessible for inspection, meets the demand that has sometimes been made when it has been thought the space ordinarily occupied by the platform switch could not be sacrificed. The principle is the same as the platform switch already described, but it is modified in form and shape to suit the particular condition under which it is to work, and it is to be noted that the mechanical adjustments required are much more exact, otherwise there would be considerable burning of the contacts, since the motorman would be unable to tell whether or not the switch contacts were on proper positions. The rheostat is arranged in sections and connections brought from them directly to cylinder contacts. A cylinder is used to commutate both resistance and field magnet coils.

An important point that has been attended to in this switch is the breaking of the circuit on a separate switch instead of on the cylinder. A snap switch, of the knife blade pattern, is employed to break the circuit at four points. It operates in connection with the cylinder shaft, to which it is connected with a special locking and releasing gear of similar design to that shown in Fig. 1. The first movement of the cylinder shaft closes the snap switch and completes the circuit through the coil. Further movement then disengages the snap switch from the shaft (leaving it closed) and the different commutations are effected. When breaking the circuit the snap switch is again brought into action.

When this form of car-controlling switch is used, the platform lever is fitted at its lower end with a bevel gear wheel meshed into another gear wheel placed on the cylinder shaft. When necessary an extension shaft fitted with one or more universal joints makes connection between the platform lever and the cylinder shaft. When this switch is placed in the middle of the car, the amount of car wiring is materially lessened and the car inspection made more easy.

With reference to controlling switches in general, it is evident that a great number of designs may be prepared that will give approximately the same electrical results in point of efficiency. In deciding then upon the merits of a new design of switch, the commercial factor relating to repairs has therefore to be very largely considered, and had designers been able to guide their work more closely from the balance sheets of railroad companies, when such had been properly kept, instead of conforming to popular notions, very much more progress would have been made in this line during the last few years.

In closing this paper it might be well that I should remark that my experience has been largely confined to what is known as the commutated field method of control, and that I have naturally expressed many of the qualities of other methods in terms of this method. If these expressions are not judged satisfactory, I leave it for those who have had a similar experience with other systems to express in their criticisms the qualities of the commutated field system in their own terms.

LARGE CURRENT BATTERIES FOR EXPERIMENTAL WORK.

Those who want to work induction coils at odd intervals always find the battery troublesome, says *Industries*. They use bichromate cells, or various kinds of batteries with queer depolarizing liquids, and find them all equally objectionable. Every electrician knows all about Planté batteries, but one is inclined to wonder how often they are used for this kind of work. Nothing can be simpler than to use a few small current cells with a little secondary battery in parallel. There is then no trouble, and for intermittent and occasional work a large current can be obtained. It may seem rather late in the day to mention such a thing as this, but the obvious is frequently overlooked.

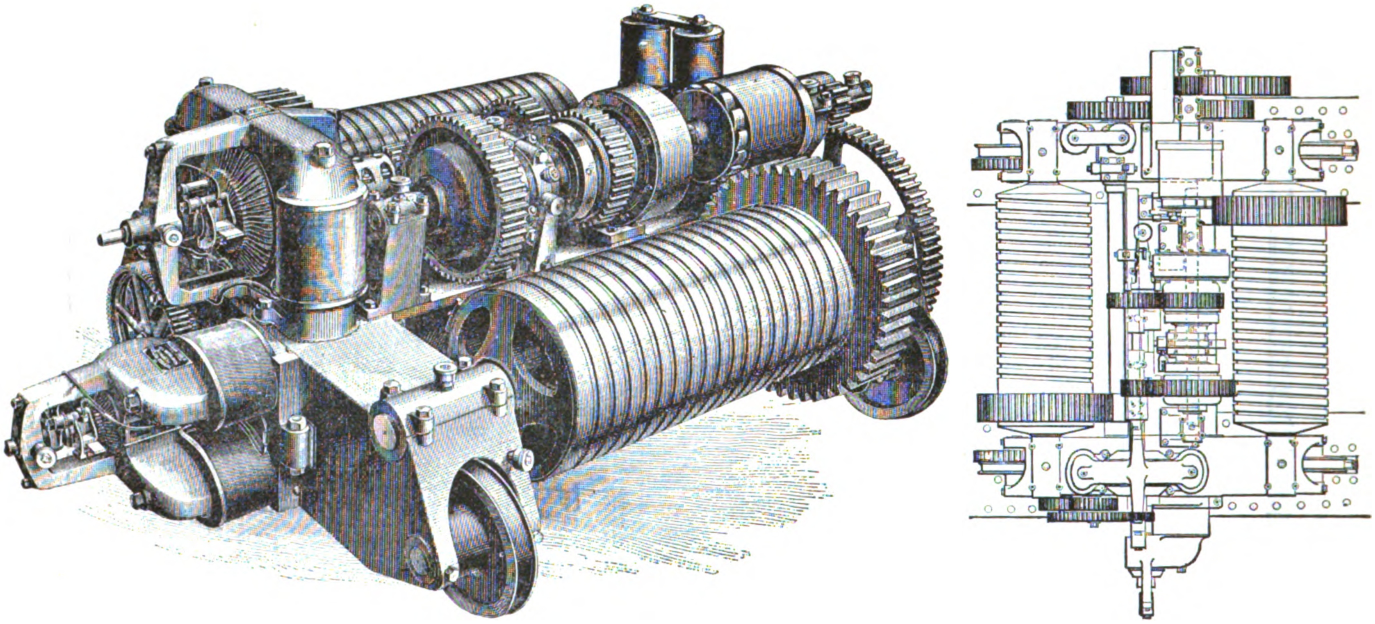
"DRUMMERS" AND THE TELEPHONE.

Traveling salesmen are not very favorably disposed toward the telephone. After quoting prices or selling goods to one concern they are likely to learn that other concerns in the same trade have been informed of the prices or sales, and that the information hampers them in their subsequent efforts to sell.

THE SHAW ELECTRIC TRAVELING CRANE.[1]

Probably the first triple motor crane put in practical operation was built from the designs of Mr. A. J. Shaw by the E. P. Allis Company and erected in their foundry in Milwaukee. Although this was an experimental machine and somewhat crude in many of its details it was pronounced superior to anything previously introduced. The molders were especially pleased with it, as it was far smoother and steadier in it movements and capable of much more accurate handling than the power cranes in use at that time.

From the accompanying engravings an idea of the general arrangement of the Shaw electric crane can be obtained. Fig. 1 is a perspective view of the trolley and Fig. 2 is a plan view of the trolley of a 15-ton crane. The bridge is moved along its tracks by means of a motor placed near one end, the power of which is transmitted through gearing to the driving wheels at each end. The trolley carries two motors, located at one side, one of which is arranged to move the trolley along the bridge while the other is so geared as to operate the hoisting drums. This crane, as are all built by this company, is fitted with duplex automatic brakes, to which in large part is due the accuracy with which the load can be handled in hoisting and lowering. These brakes not only insure against the accidental dropping of the load from any cause other than breakage of parts, but positively prevent any possibility of racing in lowering. They are entirely automatic in their operation, and do not depend for their action on the skill or vigilance of the operator. The mechanical brake is applied continuously by the reaction of the load itself, the force with which it is applied being proportional to, and increasing with the load, and released by the pull of the motor. The other is applied by a powerful spring, and is always "on" except when withdrawn by the action of a solenoid in series with the hoisting motor.



Figs. 1 and 2—The Shaw Electric Traveling Crane.

Without the mechanical brake the crane would race in lowering, as the magnetic brake is then withdrawn by the current actuating the motor, and both the motor and load act in the same direction. Without the magnetic brake the load could not be stopped promptly after either hoisting or lowering, on account of the momentum of the armature. Without the capability of instantly checking the movement of the load, accurate handling would be impossible, as when the current is thrown off it would always go a little too far or not far enough. The two brakes acting in combination give great accuracy of control, which, together with the extremely slow speed at which the crane may be run, enables the heaviest loads to be set with the greatest accuracy.

All the truck wheels are cast from charcoal iron, and the treads are chilled deep and hard and ground true. The shafts are large and the bearings unusually long. The machinery is so arranged that all parts are easy of access, and all important details can be removed and replaced without disturbing other parts. These cranes are built by the Shaw Electric Crane Company, of Muskegon, Mich., the sole agents for whom are Manning, Maxwell & Moore, of New York and Chicago.

[1] *Iron Age.*

COMPARATIVE TEST OF HIGH AND LOW SPEED ENGINES IN ELECTRIC RAILWAY WORK.[1]

BY CHAS. W. WASON.

In making this second test[2], I have endeavored to eliminate some of the causes of error that were apparent in my first test. By means of a simple device gotten up and applied by our electrician, Mr. Robert M. Fuller, to hold the pointers of the ampere meters simultaneously with the sounding of the bell, the men were enabled to get the exact reading at each interval. By a simple arrangement of slips upon which the readings were taken, the electrical horse power of any reading of the ten hours is at once obtained.

In the test of the slow-speed plant, I endeavored to secure the mechanical horse power of the two Corliss engines, by means of indicator cards taken at the same instant every fifteen minutes. I am indebted to Mr. P. A. Patterson, our engineer, for a very accurate figuring out of them. From my slips I obtained the electrical horse power at the same instant, with the result as given below. I think but little reliability can be placed upon this owing to the sudden change of load.

In order to find the dead load, owing to friction in engines, countershaft and generators, I ran the engines, countershaft and two generators with the third and fourth as motors, with the result as here shown. I then got the friction load of each engine with the other engine, countershaft and generators. This is also here given.

The number of passengers carried on each of these days and the number of car miles made are practically the same, so that in this test the "misleading" element, thought by some to exist in the former, will not present itself.

There is a larger difference in coal consumed in favor of the slow speed than in the first test, but still it is not what I expected it would show. I have been an advocate of slow-speed engines for railroad work, but the results obtained from these tests cause me to doubt whether my position is tenable.

TEST OF HIGH AND LOW SPEED ENGINES.

MARCH 13 AND 20, 1892.

	High speed.	Low speed.
Average electrical horse power developed in 10 hours	601	630
Maximum " " "	859	966
Minimum " " "	345	363
Number gallons oil used in 10 hours	7 gallons.	7 gallons.
Water consumption for 10 hours	4,170 cu. ft.	3,660 cu. ft.
Water consumption per average electrical horse power per hour	40.2 lbs.	36.3 lbs.
Water evaporated per lb. coal per hour	6.5 lbs.	7.0 lbs.
Amount of bituminous slack coal used in 10 hours	38,000 lbs.	32,400 lbs.
Amount of ashes made in 10 hours	4,444 lbs.	5,197 lbs.
Amount of fuel per average electrical horse power per hour	6.3 lbs.	5.1 lbs.
Pounds of combustible per average electrical horse power per hour	5.5 lbs.	4.3 lbs.
Number pounds of coal per car mile	7.2 lbs.	6.4 lbs.
Average amperes per 10 hours	871	909
Maximum " "	1,240	1,360
Minimum " "	550	540
Average voltage per 10 hours	514	517
Maximum " "	585	530
Minimum " "	490	500
Number of readings of 15 seconds intervals	2,400	2,400
Average temperature of water from heaters	150°	195.5°
Average " " street main	39°	39°
Average " outside atmosphere	32°	36°
Condition of weather	Light snow	Cloudy.
Height of barometer	Not taken.	29.284 inches.
Average steam pressure as per automatic steam registering diagram	88 8 lbs.	99.3 lbs.
Maximum steam pressure as per automatic steam registering diagram	102 lbs.	104 lbs.
Minimum steam pressure as per automatic steam registering diagram	85 lbs.	91 lbs.
Average chimney draught	¼″	¼″
Number of motor cars run on our line	62	62
Number of tow cars run on our line	10	10
Number of miles made by our motor cars	4,125 92 mi.	4,132.11 miles.
Number of miles made by our tow cars.	821.30 miles.	679 66 miles.
Number of passengers carried on our cars	13,551	13,489

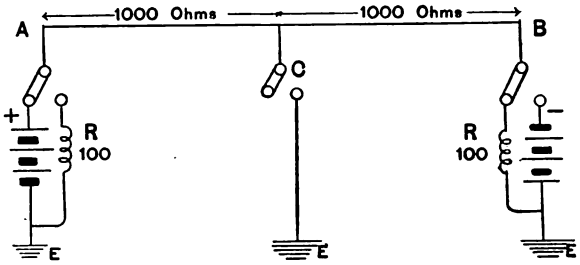
Letters to the Editor.

WORKING EFFICIENCY OF TELEGRAPH LINES.

In connection with the communication of Mr. F. W. Jones in your issue of April 6, I would like to submit the conclusions arrived at in the following:

A B is a line of 2,000 ohms resistance; batteries at A and B respectively 100 cells, with internal resistances of 100 ohms each.



Elec. Engineer

The line at B being grounded through a compensating resistance of 100 ohms, gives a total resistance of 2,200 ohms to be overcome by battery at A giving (estimating the E. M. F. at 100 volts) $\frac{100}{2200}$ = .045 ampere current strength. Reversing the conditions, and throwing line to ground at A, through 100 ohms resistance, and putting battery at B to line we obtain the same result, ($\frac{100}{2200}$ = .045 ampere current strength). Is it not evident that neither battery can possibly furnish more than 0.45 ampere through the given resistance?

Now putting both batteries to line we obtain a current strength of .045 + .045 = .090 ampere. Now throw the line to ground at C. Does not battery A give a current through the 1,100 ohms resistance A to C of $\frac{100}{1100}$ or .090 ampere *all furnished by the battery at* A? And is not the same true of battery at B? And if each battery, in furnishing 0.90 ampere consumes a certain quantity per day of zinc, will not a decrease in current strength to .045 ampere be accompanied by a decrease in quantity of zinc consumed per cell? And if each battery furnishes but .045 ampere to the line of 2,200 ohms between A and B, and .090 ampere to line of 1100 ohms between A and C and B and C, does it not follow that each battery will consume more zinc in furnishing the latter current than the former? And if the consumption of zinc is the same in each case, is it not due to the increased chemical action set up in each battery by the current from the other? In view of the foregoing is it quite correct to say that the battery at A or B furnishes the same quantity of current to line of 2,200 ohms that it does to that of 1,100 ohms?

ST. LOUIS, MO., April 12, 1892. G.

[The article by Mr. F. W. Jones in our issue of April 20 furnishes the data necessary for the answers to the above questions. —EDS. E. E.]

THE CONSUMPTION OF ZINC IN BATTERIES.

In The Electrical Engineer of April 20, Mr. F. W. Jones, commenting upon my remarks in a recent number of the same (p. 365), in reference to the quantity of zinc consumed in a battery under different conditions, expresses the opinion that I have merely reaffirmed a certain fact "without carrying with it that elucidation so necessary to lower the conclusions of mathematicians to the plane of every-day workers in the telegraphic field." Whereupon he undertakes, as he tells us, to make the subject "a little clearer."

If Mr. Jones had turned back to page 74, section 154, of *Modern Practice of the Electric Telegraph* (edition of 1892), under the head of "Quantity and Cost of Materials Consumed in the Battery" I venture to affirm that he might have found the whole subject sufficiently "elucidated," not only without mathematics, but with the aid of copious quantitative numerical examples worked out in full. It seems to me scarcely worth while to occupy space in a technical journal with a detailed explanation of such an elementary problem, involving nothing more abstruse than a knowledge of Ohm's law, and of the electro-chemical equivalent of zinc. The illustrative example subjoined by way of elucidation is, however, open to criticism. Mr. Jones says:

> In a circuit of 1,000 ohms, 100 cells will give 100 *times* stronger current than is given by one cell *alone* in the circuit, expending 10,000 more energy, and consuming 10,000 times more zinc. Each cell working in the series of 100 will consume 100 *times* more zinc than if it were unassisted by the other 99 cells.

It is scarcely necessary to point out that the above proposition could be true only if the internal resistance of the battery were zero, a condition unattainable in practice. If we assume the internal resistance of a gravity cell of the usual size to be 3 ohms, a fair approximation, we should have in the first instance:

E. M. F. $= 100$ volts; $r = 300$ ohms; $R = 1000$ ohms.

Current, by Ohm's law, $100 \div (300 + 1000) = .0769$ ampere.

And in the second instance:

E. M. F. $= 1$ volt; $r = 3$ ohms; $R = 1000$ ohms.

Current by Ohm's law, $1 \div (3 + 1000) = .000998$ ampere.

The current in the first case would be only about 77 times that in the second case, instead of 100 times as great, as Mr. Jones computes it. It might also have tended to further elucidation of the subject if Mr. Jones had explained *why* it is that the expenditure of energy and the consumption of zinc are in proportion to the square of the current, instead of contenting himself as he has done, with a mere reaffirmation of that fact.

Franklin L. Pope.

New York City, April 21, 1892.

Legal Notes.

THE INCORPORATION OF THE GENERAL ELECTRIC CO.

Governor Flower has filed the following memorandum with his approval of Senate bill No. 634, entitled "An act to incorporate the General Electric Company":

> The approval of this bill must not be considered as establishing a precedent for future legislation of this character. The measure is approved because it is claimed that its objects will keep within the State a corporation which professes to be ready to invest a large amount of capital, and which, without the concessions allowed by its proposed charter, would be incorporated under the laws of New Jersey. The reduction of tax for incorporation from one-eighth of one per cent. upon capital stock to one-twentieth of one per cent. is to make the tax uniform with that required by the law of New Jersey, so far as this corporation is affected.
>
> The other concessions in the bill are mainly such as have already been incorporated in the amendments to the stock corporation laws, which are now pending in the Legislature, and which seem likely to be passed before the close of the session. These indicate a growing sentiment in favor of less severe restrictions in our corporation laws, to the end that the investment of capital may be encouraged within the State. This is in line with the recommendations of my annual message, and reveals a tendency which, in my judgment, is wise, and will result beneficially to industrial and commercial interests.

Society and Club Notes.

FRANKLIN INSTITUTE—ELECTRICAL SECTION.

At the last meeting of this section on March 1—

Mr. C. W. Pike read a paper on "The Constant Shunt Method for the Measurement of Continuous Currents," with blackboard illustration. Referred for publication. In discussion thereon, Mr. Carl Hering stated that this method had been used successfully at the Munich Exhibition of 1882, and by himself at the Institute's Electrical Exhibition of 1884. In the latter case copper wire was used throughout, making the rate of temperature variation more regular. Mr. Willyoung also stated that he had used this method satisfactorily.

Prof. E. J. Houston read a paper on "Cerebral Radiation" which was discussed at some length and referred for publication.

Mr. Carl Hering gave some data submitted by the Oerlikon Works for the power-transmission plant at Niagara. The current furnished would be equally suitable for motors, arc and incandescent lights. The dynamo is a three-phase, separately excited machine of 5,000 h. p., and 96 per cent. efficiency. Its drum armature is made up of copper bars, is 10 feet in diameter, and, running at 250 revolutions per minute, will furnish a current in each of the three coils of 3,000 amperes, at 600 to 700 volts. The current from each machine feeds through two 2,500 h. p. transformers, capable of reducing from 25,000 volts. Cost of the line to be $20,000 for 32,000 metres, to carry up to 10,000 h. p. Total estimated cost, including generators, exciters, transformers and lines, to be $180,000.

ANNUAL ELECTION AT THE NEW YORK ELECTRIC CLUB.

The annual meeting of the New York Electric Club was held at the club house on April 21, when the following ticket was unanimously elected. The names in italic are those of officers receiving the honor of re-election: President, *Samuel Insull*; vice-presidents, *Edward Weston*, E. A. Leslie, *W. L. Candee*, H. J. Smith; secretary, *Stephen L. Coles*; treasurer, *Geo. M. Phelps*; board of managers, *Chas. D. Shain*, *Joseph Barre*, James Kempster, *H. D. Cheever*, *T. C. Martin*, John A. Seely, R. B. Corey, W. J. Morrison, *E. F. Peck*, *Dr. J. B. DeLery*, *E. E. Bartlett*, Frank R. Chinnock; committee on membership, *Charles Dutton*, C. E. Stump, *Geo. T. Manson*, *Jos. Wetzler*, C. O. Baker, Jr.

The subscriptions made by members towards lifting the Club's debt, in response to the appeal of the Board of Managers, have been so large that there is now not only the intention to carry on the work of the club as heretofore, but the hope to continue in occupancy of the commodious house at 17 East Twenty-second street.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the monthly meeting of the Council of the Institute held April 19, the following gentlemen were admitted to associate membership:

Badt, Francis B., manager of mining department, Thomson-Houston Electric Co., 6506 Lafayette avenue, Englewood, Ill.
Blades, Harry H., general superintendent the Detroit Motor Co., 1343-1355 Cass avenue, Detroit, Mich.
Coolidge, Charles A., superintendent and electrician Northern Improvement Co., Centralia, Wis.
Cory, Clarence L., professor of electrical engineering, Highland Park College, Des Moines, Ia.
Edwards, James P., firm of W. A. & J. P. Edwards, electrical contractors and engineers, Graniteville, S. C.
Flather, John J., professor of mechanical engineering, Purdue University, Lafayette, Ind.
Higgins, Eugene, assistant electrical engineer, with Frank B. Rae, 802 Hammond Building, Detroit, Mich.
Hill, George, chief engineer and general manager, Carrere & Hastings, 44 Broadway, New York City.
Hoopes, Arthur, experimenter, Edison Laboratory, Orange, N. J.
Marvin, Harry N., secretary and expert, Marvin Electric Drill Co., Schenectady, N. Y.
Metcalf, George, R., electrical engineer, with C. O. Mailloux, 45 William and 404 West 22d streets, New York City.
Parker, Hershel C., assistant in physics, Columbia College, 21 Fort Greene Place, Brooklyn, N. Y.
Scott, Charles F., assistant electrician, Westinghouse Electric Manufacturing Co., Pittsburgh, Pa.
Smith, T. Jarrard, manager electrical department of The E. S. Greeley & Co., 5 and 7 Dey street, New York City.
Sperry, Elmer A., electrical engineer, Sperry Electric Mining Machine Co., Chicago, Ill.
Stilwell, Lewis B., electrical engineer, Westinghouse Electric and Manufacturing Co., Pittsburgh, Pa.
Tischendoerfer, Fred. W., electrical engineer, Eickemeyer & Osterheld Manufacturing Co., Yonkers, N. Y.
Waterhouse, Lawrence Maxwell, consulting and practical electrical engineer, 16 St. Michael's Place, Brighton, Eng.
Wurts, Alexander Jay, electrical expert, Westinghouse Electric and Manufacturing Co., Pittsburgh, Pa.

The following were transferred to full membership:

Ayer, James I., general manager Municipal Electric Light and Power Co., 322 Pine street, St. Louis, Mo.
Emery, Charles Edward, consulting engineer, Bennett Building, New York City.

NEW YORK ELECTRICAL SOCIETY.

The 144th meeting of the New York Electrical Society took place on Thursday, April 21, at 8 p. m., at the Metropolitan Telegraph and Telephone Company's Central Exchange, 16 and 18 Cortlandt street. Thanks to the courtesy of the company, the members of the society were afforded the fullest opportunity to inspect and study this magnificent exchange, said to be the finest and costliest in the world. Only by such an inspection as this could an intelligent appreciation be had of the complexity of modern telephonic work, and of the extent to which the utmost resources of engineering and ingenuity are drawn upon to furnish telephonic intercourse for some ten thousand subscribers with lines almost wholly connected by subways. An opportunity was also given to witness the operation of the long-distance service. Mr. J. J. Carty, the electrician of the company, gave a popular running commentary upon and description of the various apparatus by means of which the exchange does its work.

Reports of Companies.

THE GENERAL ELECTRIC CO.

WITH the object of taking care of the floating debt of the Edison General and Thomson-Houston companies, forming the General Electric Co., it is proposed to issue $4,000,000 of 6 per cent. bonds.

The Edison General Electric Co. has declared a quarterly dividend of 2 per cent. The Thomson-Houston Electric Co. has declared a quarterly dividend of 1 per cent. on its common stock.

Personal.

MR. FREDERICK A. LA ROCHE.

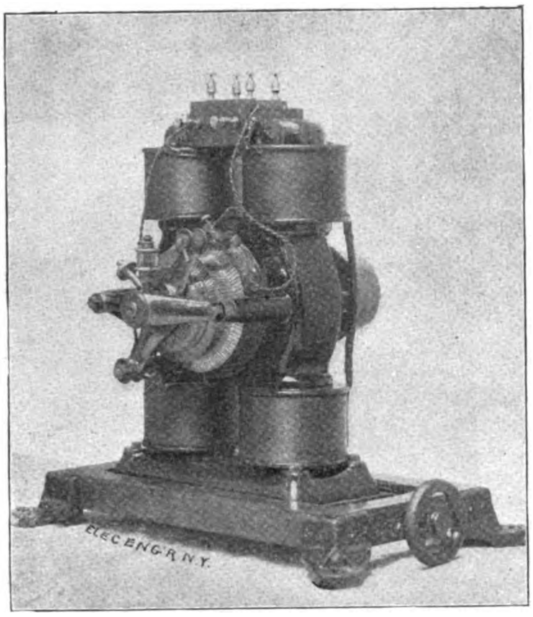
STANDING, as he does, at the head of a company enjoying so good a commercial and electrical reputation, the career of Mr. Frederick A. La Roche cannot fail to be of interest to his fellow-workers in the field as well as to all who have struggled against odds for recognition and success.

FREDERICK A. LA ROCHE.

Interested almost from infancy in things scientific, at the age of fourteen he took up the study of chemistry in this city, and, three years later, having in the mean time removed to Philadelphia, he completed a course of civil and electrical engineering under Prof. Beck, of that city. Then followed the formative period of Mr. La Roche's life; a period of more or less unsuccessful experimenting with electrical apparatus, where each new failure taught some lesson and each gleam of success incited to further effort.

In 1880 he began the manufacture of dynamo machinery and electrical apparatus, and was shortly afterward elected manager of the electric lighting company of Germantown, Pa. This plant was in so bad a condition that it had ceased to operate, and the task accomplished by Mr. La Roche was to turn it into a paying investment.

Tiring of work in which his inventive powers were hampered by routine duties, Mr. La Roche and several associates in 1887 entered into a copartnership for the manufacture of dynamos and motors. This, however, was soon dissolved and, on his own responsibility, Mr. La Roche founded the present well-known works that bear his name.



LA ROCHE CALIBRATING DYNAMO.

One of the latest examples of Mr. La Roche's skill as a designer is the "Special" calibrating dynamo shown in the accompanying illustration. This machine has a range of E. M. F. of from $\frac{1}{10}$ of one volt to 12,000 volts, and is used in the Queen & Co. laboratory for calibrating the delicate instruments manufactured by that firm.

Mr. La Roche has long been a contributor of new and useful ideas in the field of practical electricity, and his success is due to implicit belief in himself and untiring effort to make others to believe in him.

MR. NIKOLA TESLA.

THE many friends of Mr. Tesla will be grieved to learn that he has just sustained a severe bereavement in the death of his mother, with the intention of seeing whom he made his recent trip to Europe. Owing to this loss, Mr. Tesla has been detained in Gospic, Lika, and he will not return to this country as soon as he intended when he left here. It is believed that he will return early next month.

A WEDDING IN TELEGRAPHIC CIRCLES.

MISS ELIZABETH DEAN LOWERRE, daughter of Mr. Thomas H. Lowerre, Jr., was married last week at her father's home, 45 East Sixty-seventh street, to Mr. Charles Patterson Bruch, by the Rev. Dr. Ensign McChesney. Mr. Bruch was for many years the efficient secretary of the Telegraphers' Mutual Benefit Association. He then became connected with the old Empire City Electric Company, and also represented non-magnetic watch interests. For some time past he has been on the executive staff of the Postal Telegraph-Cable Company, with Mr. W. H. Baker.

Miss Edith Lowerre was the maid of honor. The bridesmaids were Miss Leila Wright, Miss Ida Schlemmer, and Miss Algie M. Hardwick, of Montgomery, Ala. Edward B. Bruch was the best man, and Charles D. Smith, Theodore H. Lowerre, Henry C. Gedney, W. D. Morgan, and Howard G. Kitt were the ushers.

A reception after the ceremony was attended by Dr. Norvin Green, John Van Horne, Commodore and Mrs. Henry Erben, Commodore and Mrs. McCann, Mr. and Mrs. Thomas A. Edison, Mr. and Mrs A. B. Chandler, Mr. and Mrs. T. L. Cuyler, Jr., Mr. and Mrs. D. H. Bates, Mr. and Mrs. William H. Baker, Mrs. Kate P. Bruch, Mr. and Mrs. Charles Lowerre, Mr. and Mrs. E. T. Gilliland, Mr. and Mrs. T. A. Brooks, Mr. and Mrs. G. F. Fagan, Mr. William Ford Upson, Mr. Edward F. Cummings.

MR. THOMAS WOOD has been selected by the directors of the new People's Electric Street Railway Company, Sandusky, O., as manager. The company expect to have their cars running by the first of next month.

THE MUNICIPAL PLANT OF THE CITY OF EASTON, PA.

About two years ago, the city of Easton found it necessary to enlarge their electric light plant. The old plant consisted of two 60 h. p. Ide automatic engines, built at Harrisburg, with an intermediate shaft containing four pulleys, two 70 h. p. return flue tubular boilers with Weitmeyer setting, one 150 h. p. Wainwright feed-water heater, and the necessary connections.

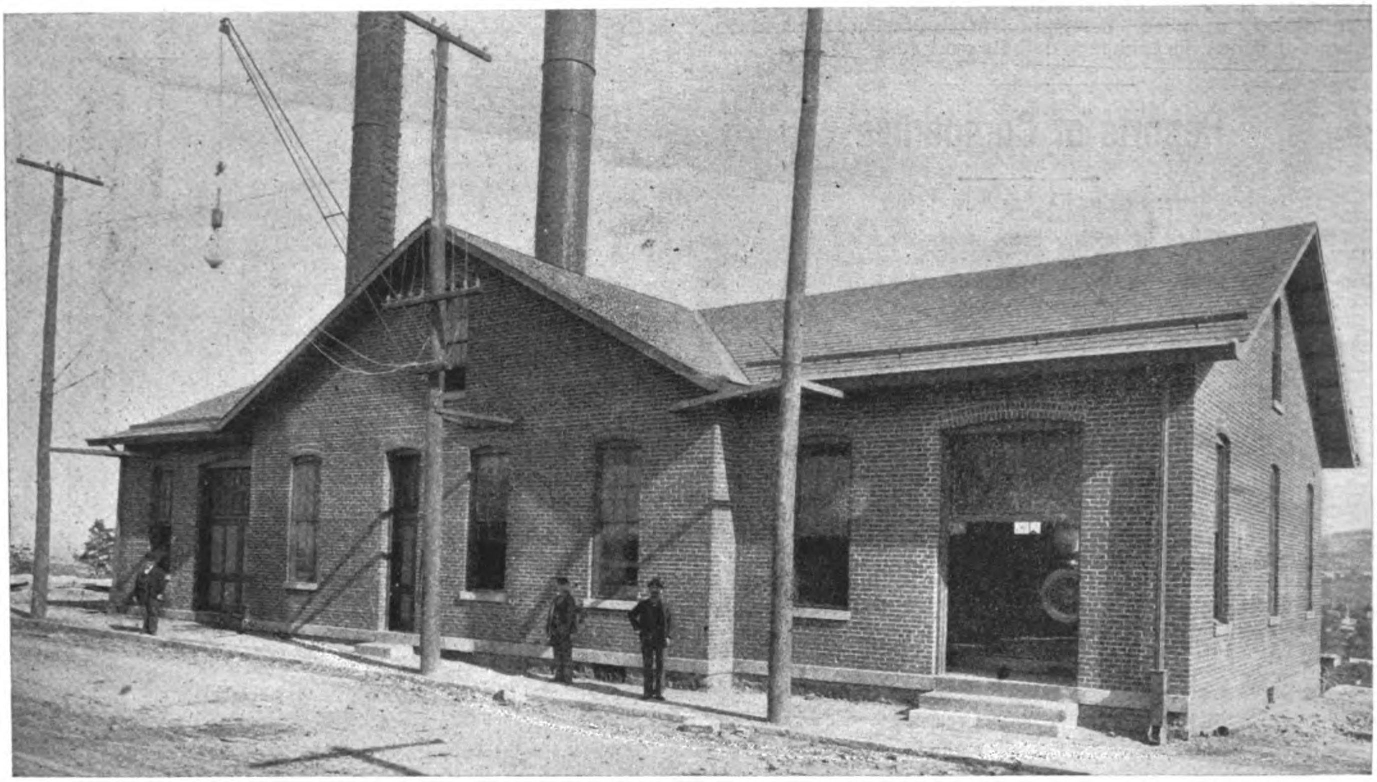


Fig. 1.—Municipal Plant of the City of Easton, Pa.

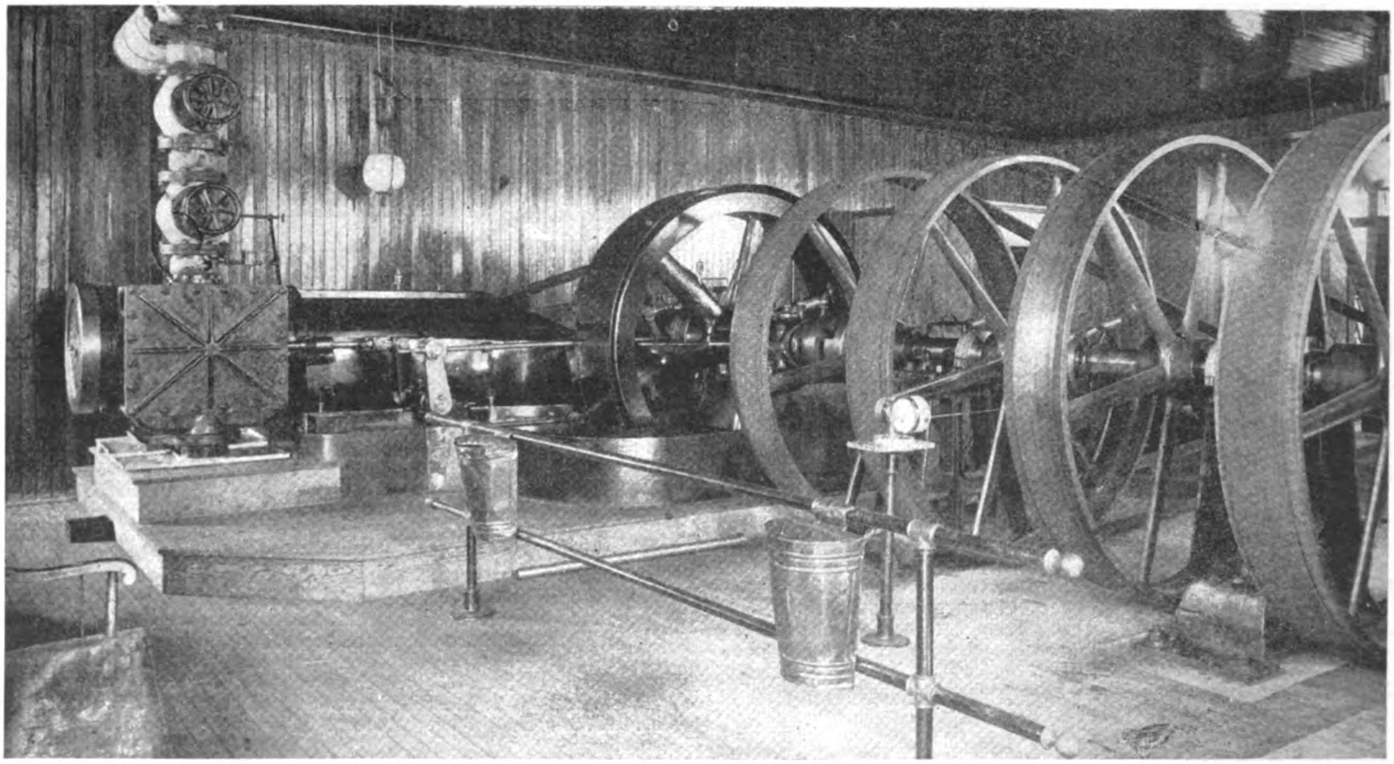

Fig. 2.—Municipal Plant of the City of Easton, Pa.

The John T. Noye Manufacturing Co., of Buffalo, N. Y., were awarded the contract for the enlarging of the old plant, and in doing so, took out all of the above steam plant, and in its place supplied two engines of 200 h. p. each, of what are known as the heavy duty "B" style type. The cylinders are 18 inch bore and 24-inch stroke, the engines running at 170 revolutions. The governor was placed in the fly-wheel. An intermediate shaft was placed between the two engines, connecting on to each engine by suitable clutch couplings, with four 84-inch drive pulleys on the shaft. The shaft, as shown in Fig. 2, is supported upon handsome cast-iron pedestals. There were supplied also three boilers, 74 inches diameter and 16 feet 6 inches long, with 126 three-inch tubes in each boiler; also one 400 h. p. Wainwright horizontal heater, and complete settings of the Weitmeyer improved gas and smoke consuming furnaces.

Each smokestack, as seen in Fig. 1, has a suitable ladder going to the top; the stacks themselves being 45 inches diameter, 70 feet high; provisions being made in this arrangement for another boiler at a later period. The entire plant is fitted out with all the little conveniences in connection with a modern plant. Mr. Robert H. Lerch, the superintendent of the plant, speaks very highly of the operation of the Rice engines.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED APRIL 12, 1892.

Alarms and Signals:—

Alarm for Hot Axles, A. Backhaus, 472,688. Filed Sept. 4, 1891.

Conductors, Conduits and Insulators:—

Insulator-Support, D. Doren, 472,529. Filed July 20, 1891.

A glass insulator supported upon an iron pin having a wooden thimble screwed upon it and into the cavity in the insulator.

Electric Conductor, W. R. Patterson, 472,648. Filed Aug. 31, 1891.

A conductor insulated with a composite covering of fibrous material and waterproof insulation, the latter forming the entire outer covering and alternating with the former in longitudinal annular sections next the conductor.

Joint for Electric Conductors, T. F. O'Connor, 472,983. Filed Jan. 2, 1892

A joint wherein the adjacent ends of corresponding conductors may be simply, cheaply and effectively united.

Insulator Bracket, C. Wirt. Design 21.454. Filed Oct. 23, 1891.

Insulator Bracket, C. Wirt. Design 21,455. Filed Oct. 23, 1891.

Distribution:—

Electric Lighting System, J. M. Lockwood, 472,623. Filed June 22, 1891.

Consists of a solenoid in the main circuit, a bar moving therein, a train of gearing automatically wound by the movement of the bar, a rotating disc and brush adapted to be connected in circuit with an alarm at the source of generation and a plate at the upper end of the bar to arrest the movement of the gearing.

Dynamos and Motors:—

Dynamo-Electric Machine, L. S. M. Pike and H. T. Barnett, 472,628. Filed Feb. 5, 1892.

Employs an annular stationary electromagnet, two concentric circles of laminated polar projections arranged in radial pairs, and sector-shaped laminated inductors revolving in proximity to the polar projections.

Electric Motor or Generator, R. M. Hunter, 472,706. Filed Nov. 12, 1891.

Has for its object to permit the brushes to be maintained at fixed points by changing the direction of rotation of the armature or varying speed.

Dynamo-Electric Machine, G. E. Dorman, 472,943. Filed Dec. 17, 1890.

Claim 1 follows:

A series of inwardly projecting pole-pieces in combination with a series of coils about such pole-pieces, each of said coils being curved to conform with the surface of a cylinder.

Lamps and Appurtenances:—

Flexible Supporting-Arm for Electric Lamps, L. T. Stanley, 472,611. Filed Oct. 17, 1891.

Electric Search Light, B. B. Ward, 472,721. Filed Jan. 13, 1890.

Consists of a cylinder provided with doors at each end and projections with movable caps, in combination with a reflector, lamp, frame, base, shaft, cord, and pulley with suitable electrical connections.

Electric Arc Lamp, R. E. Ball, 472,747. Filed Oct. 10, 1891.

An arc lamp, one of whose carbons is in the shape of a flat bar the end of which is adapted to move back and forth with relation to the other carbon which is fixed.

Incandescent Electric Lamp, G. C. Baillard, 472,800. Filed Sept. 22, 1891.

A socketless incandescent lamp in which the connections between the terminals and the circuit wires are made directly upon the base.

Incandescent Electric Lamp, G. C. Baillard, 472,801. Filed Sept. 22, 1891.

Similar to No. 472,800.

Arc Light Hanger, C. A. Pfluger, 472,935. Filed May 11, 1891.

Miscellaneous:—

Electromagnetic Valve-Controller, O. E. Lundstedt, 472,579. Filed Aug. 6, 1890.

Bracket for Electric Heaters, G. D. Burton, 472,634. Filed June 26, 1891.

Phonograph, J. L. Skilhin, 472,631. Filed Sept 12, 1890.

Art of Making Tin Plates, G. H. Benjamin, 472,691. Filed Nov. 11, 1890.

Operation consists in immersing the plate blanks in an electrolytic liquid consisting of a solution of a neutral salt and afterward in another electrolytic liquid having an acid reaction.

Electric Elevator, C. R. Pratt, 472,909. Filed April 8, 1891.

Has for its main object to provide against accidents and also to supply an apparatus easily controlled by the elevator attendant.

Magic-Lantern Advertising Apparatus, W. G. Spiegel, 472,912. Filed Sept. 15, 1891.

Cable Rack, W. M. Goodridge, 472,947. Filed Nov. 30, 1888.

Electrical Surgical Instrument, S. R. Bradley, 472,968. Filed Feb. 4, 1892.

An arrangement for detecting the presence of foreign matter in the human system.

Railways and Appliances:—

Trolley-Wire Clamp, M. M. Wood, 472,596. Filed May 14, 1891.

A clamp having two independent portions pivotally supported upon one another and provided at one extremity with clamping jaws and upon the other with means for securing the clamp to its support.

Safety Attachment for Overhead Electric Wires, C. D. Brown, 472,784. Filed Jan. 8, 1891.

An overlying loop extending from the trolley wire and surrounding the guard wire which is electrically connected with the ground.

Electric Railway Wire Suspension, A. Philipsborn & W. Reichel, 472,810. Filed Nov. 27, 1891.

Employs a second wire attached to the working wire and running nearly parallel with it; a rigid spreader between the wires and a cross-wire connected to the spreader.

Trolley-Wire Support, F. C. Prickett, 472,953. Filed Dec. 14, 1891.

Comprises a vertical bar having at one end a cavity and a groove communicating therewith at its lower margin and opening on opposite sides of the bar; a retaining plate being connected to the side of the bar and overlying the cavity and groove.

Switches and Cut-Outs:—

Electric Switch, L. T. Stanley, 472,610. Filed Sept. 24. 1891.

A push-button switch employing a flat, resilient strip as the actuating spring.

Telephones and Apparatus:—

Circuit for Multiple-Switchboard Systems of Telephone Exchanges, J. A Seely & C. E. Scribner, 472,772. Filed Nov. 15, 1886.

Provides means for connecting metallic and ground circuits for different subscribers with the same boards, and also uniform tests for determining at one board whether any line is in use at another.

Adjustable Microphone, H. O. Henneberg, 472,806. Filed Oct. 10, 1891.

Consists of a sounding funnel and vibrating membrane secured together and rotatably mounted in a frame; a carbon plate secured to the membrane and carbon bodies supported upon a flexible disc and pressing against the plate.

Canopy Telephone-Exchange Switchboard, C. E. Scribner, 472,956.

Claim 1 follows:

The combination of a switchboard containing the switches of a portion of the telephone lines of the exchange, of a canopy board placed above said switchboard, said canopy board containing the switches of other lines of the exchange.

THE BRITISH GUIANA ELECTRIC LIGHTING AND POWER CO., LTD.

A VERY fine Thomson-Houston central station has just been completed at Georgetown, Demerara, by Mr. A. H. Hardy Trott, electrical engineer for the contractors. The station is a sheet iron building erected specially for the purpose. The plant consists of two Thomson-Houston alternators of 650 lights each, and two arc machines of 12 and 30 lights respectively. These are driven by a 125 h. p. McIntosh & Seymour engine single, and a compound McIntosh & Seymour engine of 165 h. p. which is now to be run condensing. Steam is furnished by 200 h. p. of Babcock & Wilcox boilers and 150 h. p. of Grant multitubular. The demand for the light is large and growing, and a 1,300-light alternator is to be added. Mr. H. T. Moore will take charge of the plant as superintendent, relieving Mr. Trott, who will return to this country next month.

NEW SMALL EDISON LAMPS.

THE Actors' Fund Fair to be opened on May 2, at Madison Square Garden, New York, will afford electricians the first opportunity of beholding and appreciating the progress that has been made in the manufacture of incandescent lamps of small candle power. The entire illumination of the fair and the booths has been confided to the Edison General Electric Company in so far as the lamps and special design and apparatus are concerned, and every lighting effect produced will be absolutely novel. Each stand will be especially illuminated by means of the beautiful small lamps and among the wonders of the Fair the electric decorative illumination will be, perhaps, the greatest and most worthy of attention.

NEW YORK NOTES.

"A THING OF BEAUTY."—Speaking of handsome lamps it is but right to say that the beautiful "Ornamental" arc lamp which Manager Corey of the Electric Construction & Supply Co. has had placed on exhibition in his private office is certainly without a peer. This lamp is a marvel of finished workmanship, irrespective of the well-known mechanical features of the Ward arc lamp. It is wrought in highly polished brass and is of exquisite design To appreciate fully its peculiarly desirable points for hotel lobbies, handsomely equipped dining-rooms, etc., it must be seen. This company are also placing on the market a very effective short ornamental lamp expressly adapted for buildings with low ceilings.

THE PREMIER ELECTRIC CO., formerly of 11 Whipple street, Brooklyn, have moved into their new factory which has just been completed. With increased facilities as regards room, machinery, etc., they are now in a position to fill all orders for their Premier fan outfits with promptness. Their business has been so large since the introduction of their very small and reasonable priced motors that they have been compelled to build a factory and can now be found at 17 and 19 Whipple street.

PRACTICAL INSTRUCTION TO THE STUDENT.—The Premier Electric Co., 17 and 19 Whipple street, Brooklyn, are furnishing a complete set of castings and all material necessary for the putting together of their small motors. These little motors are about five inches high and will run on one cell of battery at about 3,000 revolutions, developing about $\frac{1}{80}$ h. p. or sufficient to run a ventilating fan, small or model machinery, etc. This is a rare chance for the student in electricity, furnishing as it does practical instruction in construction and winding. They issue a special circular and price list.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Successful business houses are generally known by their distinctive style of advertising.

THE ERIE CITY IRON WORKS' ELECTRIC LIGHT PLANT.

THE DUPLEX ELECTRIC Co. of Corry, Pa., last October, installed in the Erie City Iron Works a plant consisting of two 40-light Duplex arc dynamos of the type shown in Fig. 1 of the accompanying illustrations, with 60 Duplex arc lamps, and reset an old 325-light United States dynamo already in use, besides rewiring the works. These machines are driven by two Erie City automatic engines of 75 h. p. each, and the whole constitutes the largest isolated plant in Northwestern Pennsylvannia. The plant is shown in Fig. 2. One notable feature is the entire absence of rheostats or resistance coils of any description in connection with the arc generators. The rheostat seen on the wall near the switchboard is used in connection with the incandescent machine.

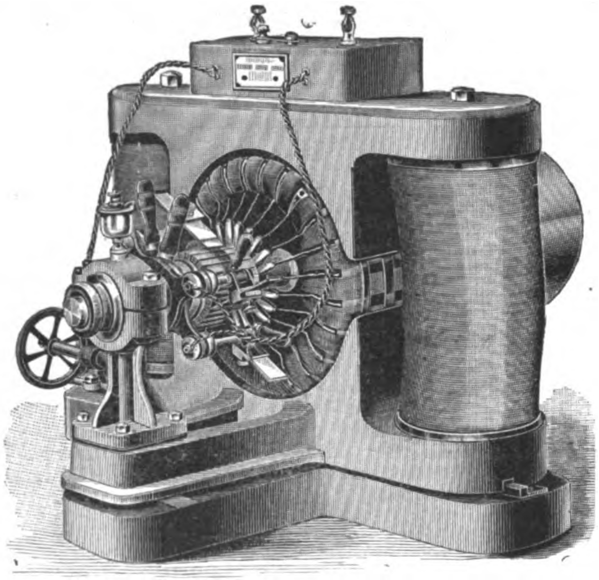

FIG. 1.—THE "DUPLEX" ARC DYNAMO.

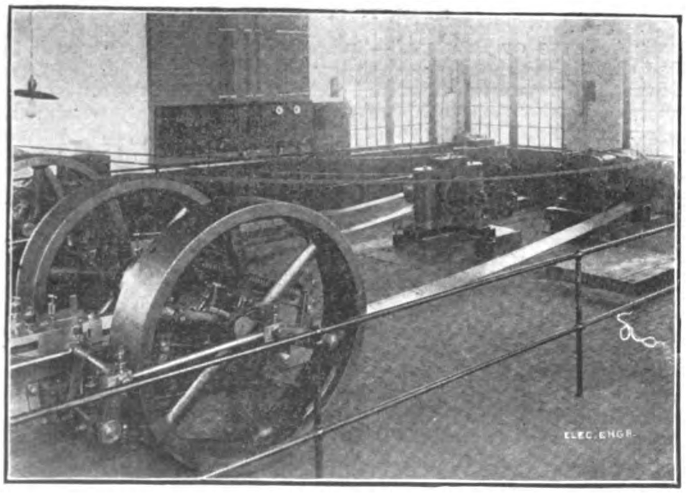

FIG. 2.—"DUPLEX" PLANT, ERIE CITY IRON WORKS.

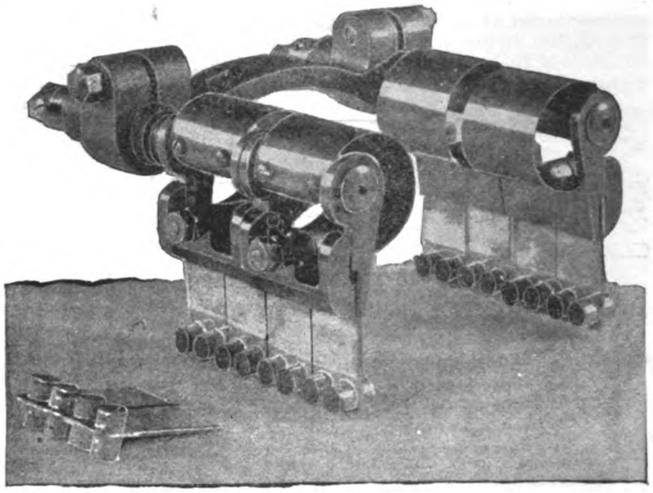
A Duplex focusing lamp for making blue prints has recently been ordered as an addition to this plant, and that the whole is all that can be desired is attested by a letter from the Erie City Iron Works saying: "Our plant is running perfectly satisfactorily in every way, and we are much pleased with it."

THE EICKEMEYER-FIELD CARBON BRUSH.

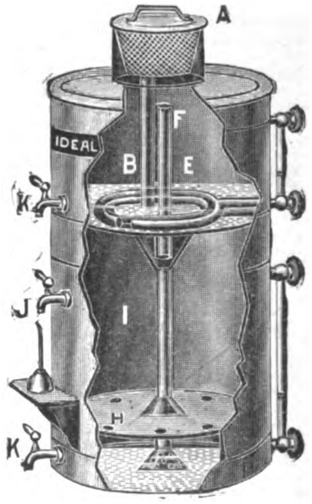
THE accompanying illustration shows a reversible carbon brush and holder in use on the Eickemeyer-Field dynamos and motors. Each set comprises four brushes like the one shown detached, which consists of four carbon pencils attached to the extremities of a divided blade spring, each carbon having an independent motion with a minimum pressure on the commutator. With this arrangement, the wear on the brushes is said to be inappreciable, while that upon the carbons themselves is but slight. When one side of a brush is finally worn down, it can be reversed and the same amount of service obtained from the other side. In addition to these advantages the brushes are interchangeable and require no adjustment.



EICKEMEYER-FIELD CARBON BRUSH.

THE "IDEAL" STEAM OIL REFINER.

THE accompanying illustration shows an oil refiner recently introduced by the Purity Oil Filter Mfg. Co., of Pittsburgh, Pa., and aptly named by them the "Ideal."



"IDEAL" STEAM OIL REFINER.

As will be seen, the construction of the filter is exceedingly simple. It is entirely automatic, can be cleaned without drawing off the oil from the reservoir, and is operated by steam and water, no filtering material of any kind being used. The operation is as follows: The chambers E and I being filled with water to a depth of 6 inches and steam connection being made with the coil, the dirty oil is poured into the receiver A, where it is strained into the pipe B and carried to the bottom of the water in chamber E. A little steam is then turned on and the refining process commences. As more dirty oil is added at the end of the first 24 hours, some of that first put in overflows into the pipe F, and is carried to the bottom of the water in the reservoir I and thence up and around the disc H. As each day's accumulation of dirty oil is added at A, the refined oil is raised until it reaches the level of the cock J, where it may be drawn off ready for a second using. The cocks K K are for the purpose of drawing off the dirt and water. The heat of the steam coil thins the foul oil and separates the grease and other deleterious matter, which settles at the bottom of the chamber E.

The Citizens' Traction Railway, the Chautauqua Lake Ice and Cold Storage Co. and the Allegheny County Court House and Jail, all of Pittsburgh, have adopted the Ideal refiner and are uniformly pleased with their choice.

THE NEW CATALOGUE OF THE ELECTRICAL SUPPLY COMPANY.

WE have before us a work which we are at a loss to classify. In many respects it is an extraordinary book. The quiet and quaint design of the gold-embossed cover gives but a foreshadowing of the feast which is spread within.

Catalogues of electrical goods have been issued for the past decade. We have seen many, if not all, of them; each was characteristic in its contents and make-up; most of them are a credit to their authors, and so far as we have known effectual in the results aimed at. As we looked over their closely printed pages, crowded with illustrations, we had no fault to find and we could not but think that they perfectly filled their mission.

The book before us is a revelation; it marks an epoch in electrical catalogue making, but we have our doubts about the fitness of it to the present day. It is ahead of its time. In its style of binding, in the evident lavish expenditure of care, intelligence, and money to make each of its 500 pages perfect it surpasses anything we have as yet seen. We even wonder if from its inception it has not grown, and developed, and expanded far beyond the idea of its compiler. We have known Mr. F. S. Terry as a worker, embodying the foremost principles and ideas of the cause which he has so diligently espoused, and we can imagine that there has been an enthusiasm, a tireless energy behind this which has made it a part of his very existence for the past few months, but still we question if it has not overlapped the course it was to have run.

Time was when a scanty outline or murky silhouette of the object was sufficient to convey to most minds the idea of its form and construction. Is it not so now? Is there a call for this artistic delineation? We turn these pages and while we question the elaboration we can but admire the genius of the artist, who has so cleverly caught the light and with his pencil molded it into almost moving, working pictures of the inanimate objects so familiar to the every-day life of the practical electrician and contractor.

Probably we are at fault in criticising the aim or intention of Mr. Terry in issuing this magnum opus of electrical catalogues. We are reminded of the instructions to a novice in the art of sculpture. He was told, "Just take your block of marble and cut away what you don't want, which of course will leave what you do want." Simple enough. But the confident beginner soon discovered that while he knew what he wanted, it was an insuperable task to tell what he didn't want. But in the collation of this book there is seen the stroke of the master hand which has cut and chipped and chiseled without falter, so that there remains only a concise, descriptive and illustrated epitome of the extensive line of goods manufactured by the company responsible for its publication.

The arrangement is embraced under the several headings: introductory; insulated wires, cables and cords; equipment material and special line devices; station equipment material; house equipment material; electric motor; tools; construction material; general station supplies; manufacturer's special material; electrical testing instruments; miscellaneous tables, formulæ, etc.

The superscription of the book reads, "Electric Light and Power Supplies, the Electrical Supply Company, Chicago, Ill. Catalogue No. 23." As a catalogue, if we must say catalogue, it will by reason of the variety and newness of its contents, its completeness up to date, its many tables, formulae and diagrams, delight every central or isolated station, electrician, engineer or buyer of electrical goods, whose good fortune it is to obtain a copy.

MR. E. E. RIES.

MR. ELIAS E. RIES, the well-known inventor, is, we understand, hard at work upon a novel and remarkable electric railway system which after many years of experimenting he has succeeded in perfecting. In this new system neither overhead wires, storage batteries, surface conduits nor underground conduits are employed; the motive current being conveyed to the car by induction from buried conductors extending along the line of travel. Mr. Ries who has given considerable attention to the development of electric railways is of the opinion that the system will revolutionize existing methods of operating railways electrically, it being not only entirely free from the objections which the overhead trolley and other existing systems are open to but also efficient and simple in operation. Mr. Ries while very reticent upon the details, has made practical demonstrations of his system with entire success, and expects to be able to make the details of the same public shortly.

There can be no doubt that if these claims can be substantiated, a most important advance in the art of electric locomotion will have been made that cannot but lead to a very general extension of this modern application of electric power as well as give rise to an entirely new type of electric railway construction.

ELECTRIC RAILWAY DEVELOPMENT AT TROY, N. Y.

THE TROY AND LANSINGBURG RAILROAD have begun the Broadway extension and loop to the Union Station. Poles have been set, and as soon as possible wires will be strung. It is expected that but a short time will elapse before regular trips will be made. The Fourth street extension to the Iron Works will be pushed as soon as the depot loop is in working order. The barn owned by the Troy and Lansingburg Railroad Co. has been transferred to the Troy City Railway Co., who will at once proceed to fit it up as a power station, plans for which are in course of preparation by M. F. Cummings & Son. The boilers are being made by T. S. Sutherland. The new station will have a frontage of 100 feet, with a depth at present of 180 feet. It is thought it will be necessary to extend still further to the westward.

The Brady property will not be used at present, but President O'Neil states that eventually it may be desirable to use it as an extra power station. The present car barn at Albia (the eastern terminus of the road) will be retained and still used for housing the cars, as the first cars in the morning are started from that end of the route.

Nearly all the iron poles to be placed from River street to the Stone Bridge have arrived, and the wooden poles for the balance of the route to Albia are already on the ground awaiting the setting. The track is being relaid and reballasted for a long distance owing to the spreading and settling during the winter, and report states that the electric line will be in operation by June 1 next, which will require exceedingly rapid work.

WEBB'S CO-ORDINATE PAPER.

WE are in receipt of a sample of book of co-ordinate or cross-section paper devised by Prof. J. B. Webb, of Hoboken, N. J., which is admirably adapted for use in technical schools, laboratories, draughting-rooms and in general wherever it is desirable to represent graphically the results of tests or calculations.

The paper is heavy wove, of superior quality, with a smooth surface suitable for nice draughting and bearing erasures well and is affected but little by ordinary atmospheric changes. It is printed with a non-actinic, olive-colored ink and the paper has a bluish tint, so that good photographic negatives of drawings, showing the ruling, can be made; the combination, too, suits black, blue and carmine inks, so that handsome work can be done. The ink dries hard so as to bear the use of rubber. The printing is done with the greatest care from copies of an original plate, which was machine-engraved with every precaution to secure accuracy, and the printing plates are renewed from time to time, to maintain the absolute sharpness of the lines.

The fifth and tenth lines are made heavier and numbered in both directions from one corner of the paper, with a distinction in the type, so that any point on the paper can be definitely referred to by its co-ordinates. A table of natural tangents is also printed on the margin so that angles can be laid off with ease and accuracy equal to that of an eight-inch metal protractor.

Two sizes of paper furnished are: "large," 17¾ x 11⅜ inches, at seven, and "small," 11⅜ x 8¾, at four cents per sheet, with a liberal discount when ordered by the trade or quantity. The paper is punched and its edges colored, and covers punched to match are furnished at 25 and 35 cents each, so that paper and drawings can be preserved in a neat form. A sample book of twenty small sheets in a cover will be mailed to any address on receipt of one dollar. For paper or samples address J. B. Webb, Hoboken, N. J.

RACINE HARDWARE MFG. CO.

THE above concern, of Racine, Wis., builders of the Racine vertical automatic engines, are just in receipt of an order from P. L. Sword & Son, of Cleveland, O., for one 3 h. p., one 5 h. p., one 6 h. p., one 8 h. p. and one 10 h. p. engine, to be shipped immediately. Their engine trade is large and active.

ELECTRIC RAILWAY WORK IN CANADA.

AHEARN & SOPER, the electrical contracting engineers of Ottawa, Ont., agents for the Westinghouse Co., have secured the contract at Hamilton, Ont., for an equipment of 30 cars and three 250 h. p. generators. This fine equipment will be furnished as quickly as possible.

EDISON CENTRE OF DISTRIBUTION SAFETY CATCH HOLDERS.

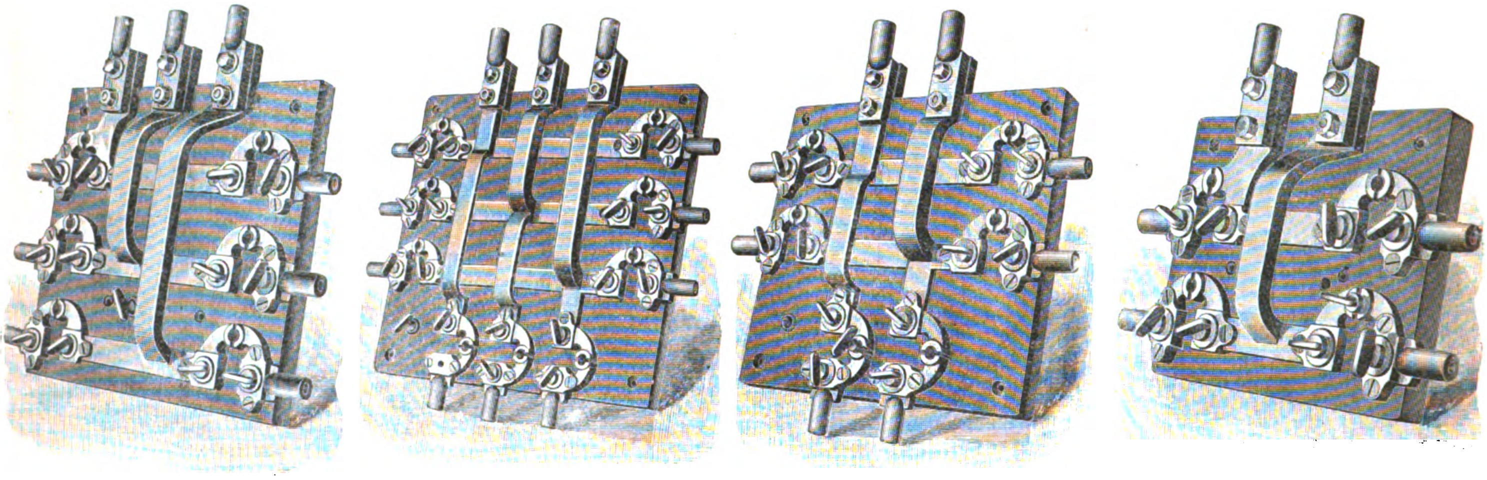
It is often necessary, in wiring a large building, to run a main line from the dynamo-room or street service wires to some point or points as centres of distribution whence smaller taps can be taken. In order to facilitate the control of the electric wires in buildings and further to safeguard them against accidents, the Edison General Electric Company have recently perfected their centre of distribution safety catch holders. Previous to the design of these devices, a number of porcelain cut-outs or ordinary safety catch holders of large capacity were used. As the capacity of the ordinary cut-out or safety catch holders was not sufficient to meet all requirements, the construction of a special device became necessary to carry the heavy current and distribute it to the various requisite points through the building. The centre of distribution safety catch holders, illustrated in the accompanying engravings, Figs. 1, 2, 3 and 4, were the outcome of this necessity.

Each branch of the device has a capacity of 250 amperes, and thus one of the appliances can be used where formerly several appliances had to be employed to effect the same end, the saving in cost of construction, and improvement in general appearance being a natural sequence. These devices are mounted on slate bases. The lugs are so constructed that they can be easily detached from the appliance, the necessary wires soldered in them, and they can then be returned to their places and screwed fast.

Provision is made of a small plug which, when inserted in its place carries the current around the safety catch when required. This short-circuiting plug is not intended for use for an extended period of time, and is only employed when changing the fuses in order that danger from arcing may be obviated. If it is necessary to have light after one fuse has blown the use of the short-circuiting plug still leaves a single-pole protection on the line; but as one plug only is furnished with each device, it would be impossible to have more than one safety catch short-circuited at one and the same time. The thumb screws are provided with large flat heads in order that they may be operated by hand, pliers or a monkey wrench. The specially designed washer under the head rises with the screw without turning on it, and the annoying operation of raising the washer with a screw-driver is eliminated.

The centre of distribution safety catch holder need not be set up outside of the dynamo-room, nor where the meter is attached to the street service, as it is frequently necessary to run two or more separate mains from this point to sub-centres of distribution in other parts of the building at which points these appliances could be placed.

These safety catch holders are made in four sizes, namely, two for the 2-wire system and two for the 3-wire system, for two and for three branches.



FIGS. 1, 2, 3 AND 4.—EDISON CENTRE OF DISTRIBUION SAFETY CATCH HOLDERS.

THE BALL ENGINE IN THE WARRENTON, MO., PLANT.

THE following letter has been received by the Ball Engine Co., of Erie, Pa.:

> WARRENTON ELECTRIC COMPANY.
> WARRENTON, Mo., April 18, 1892.
>
> BALL ENGINE CO., Erie, Pa.
> *Dear Sirs:*
>
> We started the engine purchased from you for our electric plant, last night, and the way it moved off was beautiful to behold. It is certainly a very fine and powerful piece of machinery. No vibration, no noise; in fact, and in short, it is perfect in every part and way. The satisfaction it gives is a pleasure to us, and must be gratifying to you.
>
> Very respectfully,
> C. E. PEERS,
> President.

"CANVAS JACKET" AND "FLEXIBLE CONDUIT."

THE ELECTRIC APPLIANCE COMPANY of Chicago are meeting with considerable success in the sale of "Canvas Jacket" wire and "Flexible Conduit" and have taken several nice orders for both. The trade, they say, are beginning to recognize the merits of the flexible conduit for interior work, on account of the ease with which it can be installed, as well as its qualities as an insulation. It is also being used largely as a substitute for hard-rubber tube in running wires through outside walls and partitions. The peculiar canvas weave used in covering both the wire and the conduit is remarkably effective and produces an insulation that it is claimed is well nigh waterproof as well as weatherproof. The insulation is made of the same material used in the heaviest tent canvas. The waterproof qualities of the wire are largely increased, however, by a liberal application of compound, thus producing an insulation far superior to anything that can be secured, it is said, by the braiding process.

LARGE POWER FROM A SMALL AMOUNT OF WATER.

THE PELTON WATER WHEEL CO. have recently furnished the Commercial Mining Co., of Arizona, a power plant, which affords a good illustration of the extraordinary results that can be obtained from a small quantity of water under a high head as also the estimate of value placed upon water-power where so large an outlay is made for a comparatively small amount of power. This plant consists of a 4-foot Pelton wheel which runs under a 1,200-foot head at 699 revolutions per minute developing 45 h. p. using a nozzle tip $\frac{58}{100}$ of an inch in diameter. Also a 24-inch Pelton wheel running under the same head at 1,380 revolutions developing 20 h. p. with a nozzle tip $\frac{35}{100}$ of an inch in diameter.

These wheels run a concentrating and smelting plant including rock breaker, blowers, pump, etc. The pipe line is 20,000 feet in length, the upper end being 6 and 5 inch casing and the lower end 5-inch lap-weld pipe. All the water supply that can be counted on during the dry season is a flow of about 30 cubic feet per minute. The large expenditure here made in pipe line for results obtained will indicate the advantage that water-power has over steam under much more unfavorable conditions than generally exist in such places.

THE NEW "A. B. C." CATALOGUE.

THE new "A. B. C." catalogue is just out. It is a book of over 270 pages, handsomely bound and contains prices and descriptions of almost every article required in the construction and operation of electric light, power and railway plants. Part of the book is devoted to railway appliances and shows a number of insulating devices and other specialties, which will be kept in stock at the New York store.

From an examination of this book, it is apparent that there have been during the past month many novelties brought out in the line of electric light fittings and fixtures, about 50 pages of the catalogue being devoted to new goods.

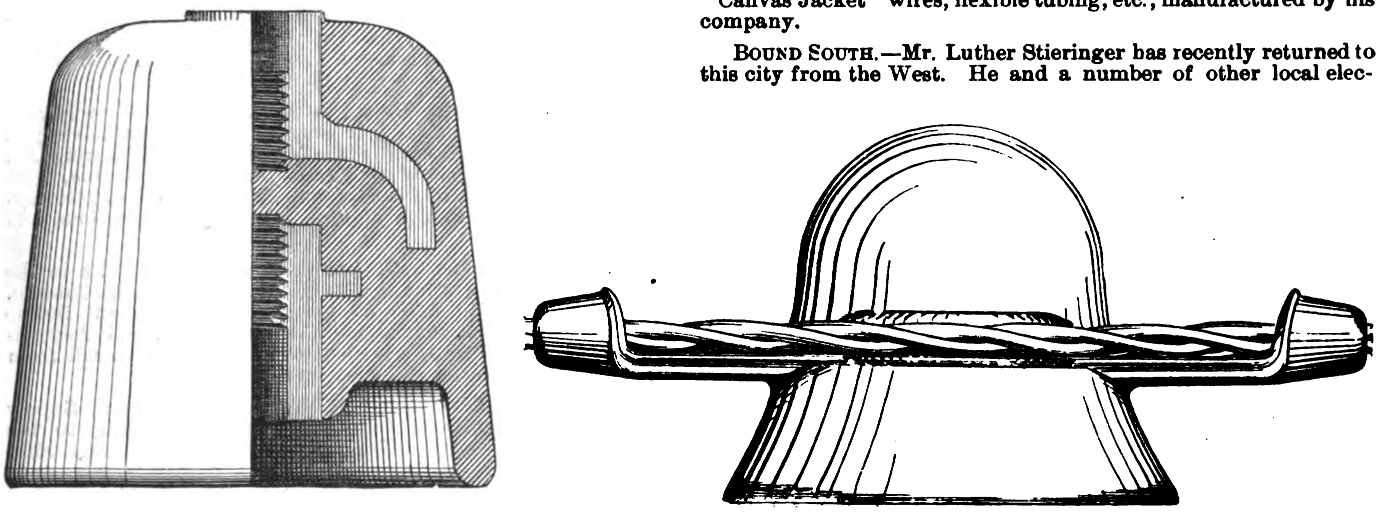
The subject of fan motors is given special prominence in this catalogue, several new forms of machines being described; among them are a $\frac{1}{10}$ horse power motor and fan for 110 volts, direct current, which appears to be one of the most compact outfits of the kind yet put on the market. The catalogue also describes a new alternating fan motor, which has several advantages, and on account of its high efficiency is likely to be largely called for by stations using the alternating system.

THE DETROIT ELECTRICAL WORKS IN THE WEST.

One of the most active and progressive of the newer Western communities is Sioux City, Ia., which has always been quick to show an appreciation of the good qualities of electrical inventions and apparatus. It is very proud of its electric railways, and will now hear of nothing but the best for further work in that line. An evidence of this is given in the placing of its contract by the Sioux City & Leeds Electric Street Railway. The officers of this road have been making a personal investigation of electric railway work all over the country, and were extremely critical in their point of view. Such being the case, the Detroit Electrical Works, of Detroit, Mich., may well feel pleased and highly complimented at capturing a contract from this road for six miles of overhead construction, and five 40 h. p. motor equipments with car bodies, trucks, etc., complete. It is understood that the apparatus is wanted as soon as possible, and the increasing facilities of the Works will enable a prompt execution of this and a number of other large orders recently received.

THE "ROUND TOP" AND "SALEM BELL" TROLLEY LINE INSULATOR.

We illustrate this week two new forms of trolley line insulators, now being manufactured by the Johns-Pratt Company, of Hartford, of which the H. W. Johns Manufacturing Company, of New York, are the selling agents. Fig. 1 represents the "Round Top" insulator, specially designed for the most substantial work. It consists of a metal shell throughout, with projecting lugs for the span wire. This outside shell is filled with moulded mica insulation, which surrounds the central metal nub, which carries a $\frac{5}{8}$ inch bolt. The edge of the skirt is turned down over the insulation, and the whole insulation is anchored in such a way that it cannot be damaged by the most severe handling, or by the accidental concussion of the trolley wheel, should it slip off the trolley wire. Fig. 2 represents the "Salem Bell" insulator also used for a straight trolley line insulator. This insulator is very similar to their regular line insulator, but as will be seen has one important improvement, in the nub or receptacle for the suspending bolt both top and bottom. This nub has been increased in length, and counterbored so that the screwed part does not take the whole of the side strain but is relieved by the bolt fitting snugly into the counterbore. It has been found that the weakest part of the bell insulators was at the point where the screw entered the metal nub, and experience has shown that this weakness is entirely overcome by this change, and altogether prevents any danger of the threaded screw from breaking. The top nub is counterbored $\frac{3}{8}$ inch and the bottom one $\frac{5}{8}$ inch, which makes the shape of the insulator a little longer than the old one, but not so great in diameter, the total weight being about 18 ounces.



Figs. 1 and 2.—The "Round Top" and "Salem Bell" Insulators.

GHEGAN'S IMPROVED DUPLEX.

In our issue of April 6, we described a new duplex system of telegraphy invented by Mr. J. J. Ghegan of this city. We are now glad to inform our readers that full details can be obtained from the inventor at the office of Messrs. J. H. Bunnell & Co., 76 Cortlandt street.

The system should prove of especial value in cases where a number of way stations are operated upon a single line, as is the usual practice in railway work, permitting, as it does, the sending of two messages in the same or opposite directions at the same time.

NEW YORK NOTES.

West Troy, N. Y.—The new board of electric light commissioners have held their first meeting and perfected their organization by the election of C. H. Fort as president, and Clinton Robinson, secretary. A general presentation of matters pertaining to the system was had, and with the assistance of Village President Royers, a thorough review of the present equipment and its needs was made. The commissioners will inspect the plant and service at once. A thorough revision of methods now in use has been determined upon, and will be of benefit to the taxpayers. It is proposed to secure sufficient additional lamps so as to have with those recently purchased a first-class light on every pole in the village, and a reserve of ten lamps for repairs and emergencies.

The Watervliet Railway Company of Albany, N. Y., are contemplating extensive improvements. The track from Livingston avenue, Albany, to the baseball grounds is to be rebuilt as well as the track from State street to South Ferry. The track in West Troy is also to be relaid. Forty new cars of 20 h. p. each have been ordered to replace the present ones of 15 h. p., also ten new summer or open cars. The power house at North Albany will be abandoned, and the company will equip its South Pearl street station with two new 500 h. p. dynamos.

Mr. Herbert H. Brooks, general manager of the American Circular Loom Co., of Boston, spent a few days in the city last week. While here Mr. Brooks completed arrangements with the firm of Doubleday & Mitchell whereby they will act as agents for "Canvas Jacket" wires, flexible tubing, etc., manufactured by his company.

Bound South.—Mr. Luther Stieringer has recently returned to this city from the West. He and a number of other local electricians are packing their traps now for North Carolina, where as capitalists and sportsmen they have large interests to look after and get fun out of.

J. Jones & Sons, 602 West Twenty-second street, announce that prospects are very bright for an enormous business. Large orders have been received by them recently for various goods, but the bright, particular star of their trade is the bell which they make with a dust-proof contact protector. This device literally speaks for itself, as, in spite of its large sales, it has not been pushed at all, but is sold entirely on its merits.

Fitchburg Engine Co.—The recent sales reported by the Fitchburg Engine Co. are three 150 h. p. tandem compound high-speed engines to the Hull Electric Light Co., of Hull, Mass.; one 75 h. p. slow-speed horizontal engine to Noble & Cooley, of Branville, Mass. They have also just completed the installation of, and have started a 75 h. p. engine for Healy & Co., 51st street and Broadway, and still another at the Union League Club, this city.

The Storage Battery Supply Co. have removed their works from 158 West Twenty-seventh street to the northeast corner of Twenty-third street and First avenue.

NEW ENGLAND NOTES.

Massachusetts Electrical Engineering Company, of Boston, have sold all the machinery and material used in the manufacture of fuse wire, together with the good-will of the business, to the Shawmut Fuse Wire Company, of 85 Water street, Boston, This company has been organized expressly for the purpose of manufacturing fuse wire and links of the highest grade and will have every facility for filling orders in a prompt and satisfactory manner. All the wire and links which they manufacture will be tested, as heretofore, at the laboratory of the Massachusetts Electrical Engineering Company, and a certificate of test signed by them will accompany each spool of wire and lot of links sold. The Shawmut Fuse Wire Co. will hereafter conduct the entire business, and will furnish these well-known fuses at the same prices as heretofore for the present, and guarantee in every way the same thorough reliability as before. Mr. Russell Robb is manager of the company and has had an extensive experience in this particular branch of business, so that customers may place their orders with the same confidence as before.

Mr. Levi Cofren, who has been for several years connected with the Pettingell-Andrews Company, of Boston, has recently been appointed general traveling agent for New England and New York State of the Washburn and Moen Manufacturing Company, in their insulated wire department. Mr. Cofren has made a specialty for some years of the insulated wire business, and is particularly well adapted to this line of trade. He leaves the Pettingell-Andrews Company with the best of good wishes, and is sure to achieve success in his new and broader field, as he has the respect and good-will of hosts of friends in this section of the country.

The Johns-Pratt Company, of Hartford, are busily engaged manufacturing the insulating line material for the Philadelphia Traction Company, of Philadelphia, Pa. This order comprises the line insulators for the span work, together with the strain insulators, centre pole bracket arm insulators, guy insulators and feed cable insulators. The Johns-Pratt Company are exceedingly busy both in the manufacture of their vulcabeston and molded mica specialties, and have now got their factory in first-class running condition, turning out both kinds of goods in large quantities.

The John Becker Manufacturing Company of Fitchburg, Mass., encouraged by the success which has been achieved by their vertical millers Nos. 1, 2 and 3, have decided to manufacture still another size which will be called their No. 4, and which will be capable of comparatively heavy work. The success which has attended the introduction of the Becker milling machine has amply proven that the vertical spindle millers are now being recognized as superior to horizontal millers for many purposes.

Mr. R. F. Ross has brought out a monthly paper called *Electrical Progress and Development*, as a successor to *Modern Light and Heat*. It is his intention to devote his new journal strictly to electrical work in New England, a decision that seems wise considering how active the field is and how well known in it Mr. Ross is. The paper is neat, newsy and well printed, and if there is any saving virtue in nerve, grit and perennial good nature, Mr. Ross will "get there" in great shape.

The Iona Manufacturing Company, of Boston, has recently been organized with Mr. Norman Marshall, president, Mr. H. P. Stanwood, treasurer; Mr. H. M. Nicholls, secretary; Mr. S. L. Whipple and Mr. John C. Holman, as directors. The capital stock of the company is $15,000, and it is their intention to go into the manufacture of general electrical supplies and specialties. The Redding Electric Company, of Boston, will act as sole selling agents.

The W. S. Hill Electric Company, of Boston, have issued a revised price list of their extensive line of electric switches. Their motto is "best quality—lowest price," and they aim to maintain the high quality of the goods for which they have already earned a wide reputation.

J. H. Horne & Sons Co. have decided to build a new machine shop 64 feet wide by 107 feet long and have placed the contract for same with the Berlin Iron Bridge Company, of East Berlin, Conn.

WESTERN NOTES.

H. W. Caldwell & Son, sole manufacturers of the improved "Charter" gas engines which are built for operation by gasoline, coal gas or natural gas, have issued a handsome catalogue of their engines which gives full particulars of various methods of operation and a great many highly valuable details regarding their working in general. The catalogue is handsomely illustrated with views of their engines showing details and contains a short and clear description of the various parts. These engines are rated in actual horse power and are of the very highest efficiency and best workmanship using only the gas in exact proportions to the amount of work they may be doing. They are very reasonable in price and especially adapted for running dynamos and can be used without any counter-shaft, being belted direct to the machine and giving a perfectly steady light, which is quite a remarkable achievement. The cost of running the improved "Charter" gas engines with gasoline at 10 cents per gallon is stated as being one cent per hour for each indicated horse power.

Mr. Eugene A. Erich, consulting and contracting mechanical and electrical engineer has been appointed general Western representative of the Waddell-Entz Electric Company, of New York. He has opened a temporary office at 438 Rookery but will move into the Monadnock Building about May 15.

Kohler Bros, the Western agents for the Eddy Electric Manufacturing Company, owing to lack of room in their present quarters at 341 Rookery, will remove May 1 to a handsome suite of offices at 1417-1418 Monadnock Building, corner Jackson and Dearborn streets, Chicago. Their business in motors for the past year has been very large and is continually increasing, and they are now equipped with facilities to carry a large stock of machines on hand and to handle their growing business more expeditiously.

The Lunkenheimer Brass Mf'g. Co., of Cincinnati, O., are preparing for the World's Columbian Exposition a most elaborate display of their popular specialties in valves, sight-feed lubricators, oil and grease cups, etc. They will also exhibit a complete line of brass and iron goods, besides some novelties in steam whistles and sight-feed lubricators. They report business exceedingly brisk, being crowded with orders for their numerous specialties and receiving large contracts for special work for United States cruisers.

The Electric Appliance Company continue to receive the strongest possible testimonials from users of Paranite wire all over the country to the effect that it successfully stands the severest tests to which it has been put and is proving entirely satisfactory where other wires have failed. They feel very much encouraged at the outlook for spring business and are rapidly pushing Paranite wire to the front.

Mr. W. S. Reed, consulting and contracting engineer, has opened an office also at 1222 Monadnock Building, where he will devote his attention to furnishing plans and specifications and supervising construction of all kinds of electrical plants, waterworks or other engineering work. Among his latest work is equipping the Harvey Transit Co., of Harvey, Ill., with waterworks, electric lights and railway plant.

The New Equitable Building at Des Moines is to have a very complete electric light installation. Contracts have just been placed with the Chicago office of the Pond Engineering Co., for one 25 and one 60 h. p. Armington & Sims engine, with foundation boxes. The Pond Company are also to deliver and erect these engines in Des Moines, with pipe connections and foundations.

Mr. Ernest Hofer, well known in electrical circles in the West, has opened an office at 1,222 Monadnock Building, Chicago, where he will handle a line of specialties, among them Bishop wires and cables, Electrix sockets, switches, etc., and Pennsylvania incandescent lamps. He will be glad to receive a call from his many acquaintances and customers.

The Western office of the Electric Construction and Supply Company has removed from the Phenix Building to the Unity Building, Chicago. The latter is one of the nicest office places in the city.

Mr. J. S. Gustin, formerly with the Electric Merchandise Company, of Chicago, as purchasing agent, has accepted a position in a like capacity with the Railway Equipment Company, of Chicago.

Mr. J. T. Macartney, recently traveling salesman for the Electric Merchandise Company, has resigned his position and has accepted a similar one with the Railway Equipment Company.

The Railway Equipment Company have just received an order for all the line equipment for the extensions to be made by the West End Street Railway Company, of Rockford, Ill.

WASHINGTON NOTES.

The Washington Construction Company, of Washington, D. C. (Messrs. Pardoe and Messner), have the contract for the lighting of the city of Lewisburg, Pa., with arc and incandescent lights. Mr. Pardoe is now on the ground constructing the plant. They expect to turn on the arc lights by the first of June. This same firm is also wiring the Union Building, of Washington, D. C., which is to be occupied by the City Post Office until the new one now building by the Government is completed. It is the largest piece of incandescent wiring ever done in the city of Washington. Out of five wires submitted, Bishop was selected.

The C. and C. Motor did a wonderful piece of work again a few days ago. The Star Newspaper Building, of Washington, D. C., had its entire steam plant destroyed a week or so ago. They had on hand a 20 h. p. C. and C. motor for just such emergencies. The motor itself had a very narrow escape from being burned, beside being thoroughly drenched with water. Yet the following day the motor was put in service and up to this date has been doing an actual 24 h. p. work for five hours a day.

Electrical Engineer.

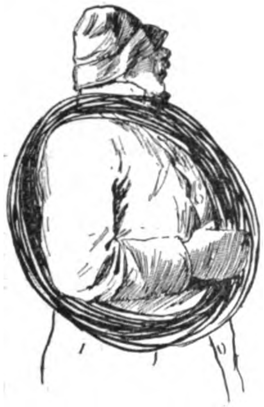
VOL. XIII. MAY 4, 1892. No. 209.

LONG-DISTANCE TELEPHONY.—I.

BY

Herbert Laws Webb

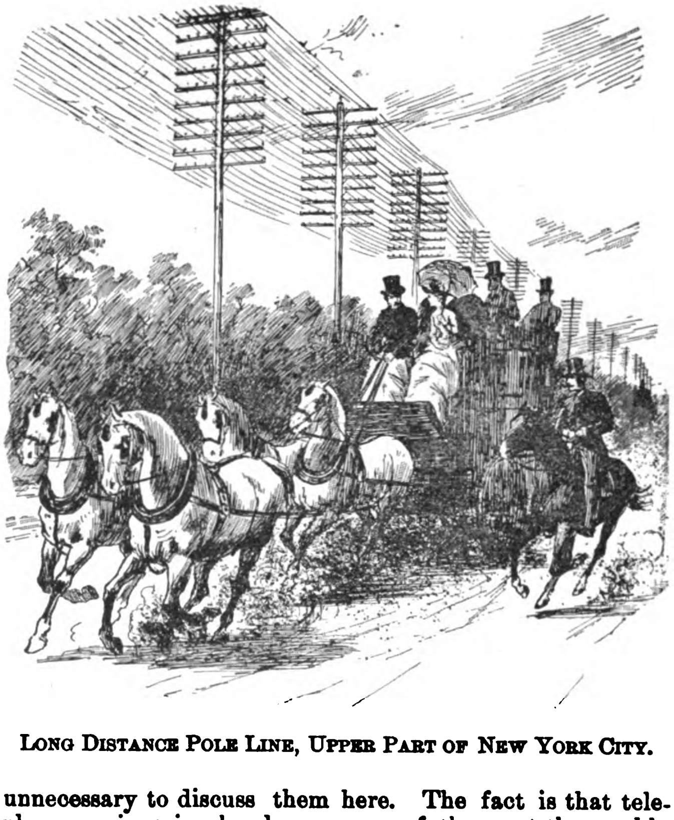
I.



In the introduction of any fundamental invention or discovery into the great field of commercial electricity it would need a bold and long-sighted prophet to foretell the developments of which that invention might be capable, the refinements and improvements in itself and in the accessory and auxiliary appliances with which a new thing soon becomes surrounded, and the complicated systems and methods which are evolved and built up as its working is rapidly extended. The incandescent lamp, when it emerged, a practical instrument, from the laboratories of the various inventors who invented it, hinted nothing of the revolution in dynamo building that it was to bring about, nor of the numerous beautiful measuring instruments that it was to call into existence, nor of the study of the heating of conductors and best methods of distribution that it was to give rise to, nor of the acrimonious discussions before the scientific societies and in the technical journals that it was to provoke, nor of the thousand and one ingenious appliances that were to be invented to add to its economy, safety and trustworthiness. So with the telephone. When Prof. Bell produced his speaking telephone 16 years ago who was there that thought of multiple switchboards, of 100-wire underground cables, of huge buildings planned out from basement to roof to serve as telephone exchanges, and what wild dreamer would have dared to prophesy daily business talks between New York and Boston, Buffalo, Pittsburgh or Cleveland?

Long-distance telephony has within the past few years been brought almost to the level of an exact science. It is an exact science in so far as whatever it attempts to do is done well and the results are assured beforehand, but it would be by no means wise to attempt to define the limits of the transmission of speech by telephone. So much has been done in improving the apparatus employed and in the construction and arrangement of lines that distances considered impossible a few years ago have been exceeded without any difficulty. However, we do not wish to discuss here what can or cannot be done by the telephone from the scientific point of view, but rather to describe just what it does commercially, and how.

The American Telephone and Telegraph Company, colloquially called the Long-Distance Company, has been engaged for the past five or six years in developing interurban telephony. Starting with comparatively small beginnings the long-distance telephone system has reached a magnitude that few people except those who are engaged in telephone work or who are users of the telephone have any idea of. This development has been attained by sound scientific work in every detail of instrument and line construction and by energetic business management, which have resulted in the building up of an industry that is one of the great achievements of commercial electricity. The actual development of telephony from both the electrical engineering and business standpoints has not been so closely followed by the technical press as that of the other great industrial applications of electricity. There are various reasons for this scarcity of telephonic literature, but it is unnecessary to discuss them here. The fact is that telephone engineering has become one of the most thoroughly scientific divisions of electrical work, and its application is exemplified in the most striking manner by an inspection of the vast plant of the long-distance telephone system. From the business and commercial point of view the subject will be found equally interesting, because the long-distance telephone service offers to business men facilities which cannot be given by any other kind of communication.

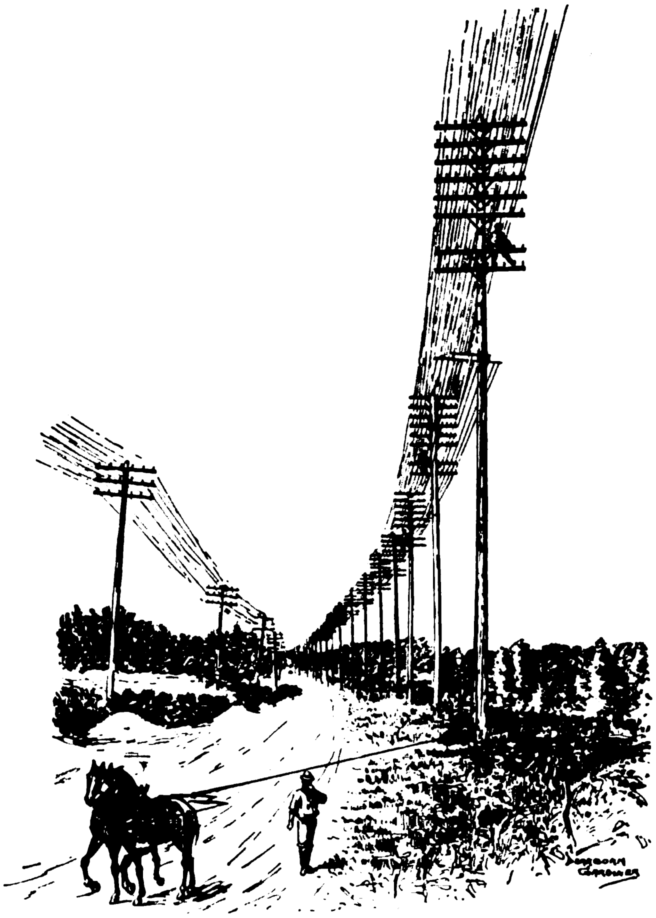


LONG DISTANCE POLE LINE, UPPER PART OF NEW YORK CITY.

II.

Even when the success of local telephone service was abundantly assured, some little time elapsed before interurban telephony was seriously attempted. It was found early in the career of the telephone that conversation could be maintained over lines 40 or 50 miles long, but from this to establishing communication between various towns as a commercial undertaking was a very long step indeed. An early instance of the recognition of long-distance communication as a distinct branch of telephony occurred in 1881. In November of that year, Gen. C. H. Barney, general manager of the Inter-State Telephone Company, issued a circular calling attention to the advantages of a projected ex-territorial exchange between Boston and Providence. This circular described the proposed method of communication in the following terms:

"A limited number of parties in Providence and Boston, who have frequent occasion to communicate with each other, will be formed into an exchange, a subscription to which entitles any subscriber in Providence to talk with any subscriber in Boston, or *vice versa.* A call bell, telephone and transmitter, all of the latest patterns, will be placed on the premises of each subscriber, and connected by a *metallic circuit* with central operating tables in Boston and Providence, which tables will be connected with each other, also on a *metallic circuit.*



ELEC. ENGR. N.Y.

STRINGING TEN TELEPHONE WIRES AT A TIME.

"Thus, any subscriber in one city can quickly be connected and talking with his correspondent in the other city *on a complete metallic circuit, ensuring a perfectly quiet line,* free from all sorts of induction or earth currents, with no possibility of being disturbed by the conversation of others or of having your own conversation overheard by them. No condition of the atmosphere and no trouble short of an actual breakage of the line can interfere with the perfect working of this system.

"Each subscriber has, practically, *a private line on a metallic circuit;* the only perfect system of telephony yet devised."

It will be noticed that in this letter special stress is laid, by italics and careful reiteration, on the importance of using a metallic circuit and the perfectly quiet line which resulted. A metallic circuit was a *rara avis* in those days and even the meaning of the term was scarcely understood. It is related of a young lady operator at Providence that on speaking over the line to Boston she expressed surprise at finding it so quiet in comparison with the noisy, buzzing, rattling grounded circuits that she was accustomed to deal with. On asking the reason she was told from the Boston end that they had the line "fixed on a metallic circuit." "Well, I only wish you could send me one over here!" was the remark she made.

A complete metallic circuit, ensuring a perfectly quiet line, naturally strikes one as it did the pioneers of the Boston-Providence line as being the first desideratum of long-distance telephony.

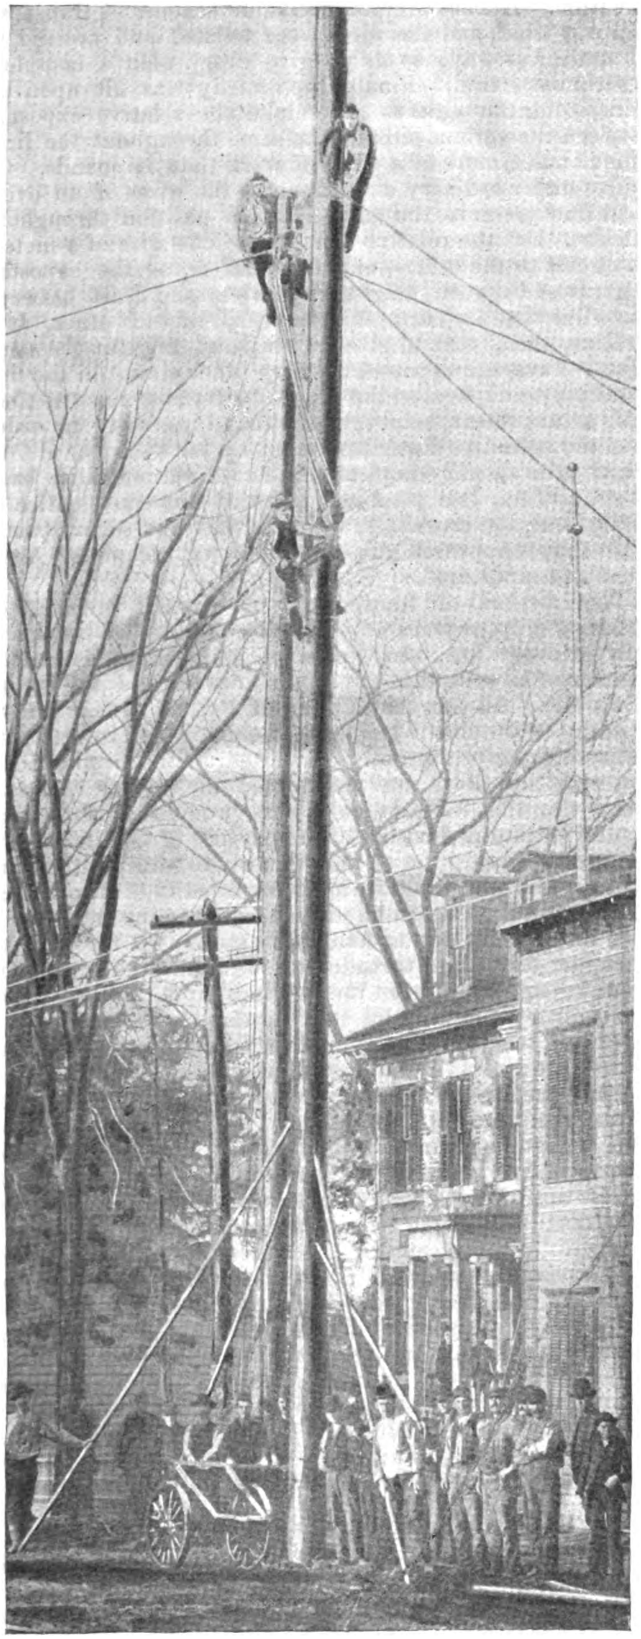
But there are many other important points connected with the establishment of a system on a large scale and even the metallic circuits themselves, when congregated together in close proximity, were found to disagree with each other and to need very careful treatment to secure perfectly quiet lines. As to the transmitting and receiving instruments, operating apparatus, central office equipments and the various details which go to make up a complete line, problems without number have been developed in connection with each and every one of them.

By attacking and solving these problems the long-distance telephone service has been brought up to its present state of matchless efficiency, when it provides talking wires between towns over 600 miles apart and maintains them intact during storms which hopelessly disable the telegraph lines.

It was not until the year 1884 that the project of establishing long-distance telephone communication in a systematic manner took definite shape. Previous to that time trunk lines had been erected and successfully worked between towns fifty miles apart and some experience had been gained. This was not seriously considered long-distance work, and when the American Telephone and Telegraph Company was formed its plans were laid out on a much more ambitious scale. The first line built by the company was between New York and Philadelphia, a distance of about 100 miles. This line was completed in 1885 and more information about the conditions required in long-distance telephony was obtained from it than any amount of text-book or theoretical study could possibly afford. So little was known about the working of long telephone wires at that time that the results obtained from the Philadelphia line were a complete revelation in many ways and in bringing it to the point of successful working the study of scientific telephone engineering received a marked and lasting impetus.

III.

From the very first the Long-Distance Company has set itself a high standard of overhead line construction. It was determined at the outset that nothing should be left undone in this direction to ensure the best results that good material and first-class workmanship and supervision could give. Every line is built according to rigid specifications, which contain a full description of every part of the material to be used and explicit instructions as to the manner in which the work is to be done, allowance being made for almost every imaginable condition that may be met with in building a line across country. The wire, of course, is hard-drawn copper, the standard size being No. 12 B. S. G. (.104 inch diameter) having a resistance of 5.2 ohms to the mile. All joints in the wire are made with the well-known McIntyre sleeves which make a thoroughly strong joint mechanically and give perfect electrical contact. In building a new line the wires are strung with great rapidity. Ten wires are put up at a time. The coils of wire are mounted on revolving drums placed in line near the first pole; the ends of the wires are attached to a bar which is drawn along by a team of horses. In this way over seven miles of wire, that is, ten wires each three-quarters of a mile long, can be strung up over the cross-arms in a very short time. A lineman is stationed on each pole to lift the bar over the top of the pole as it comes along; if the wires are drawing over a lower cross-arm the bar can be taken apart so as to pass the pole. The wires lie on the cross-arms, the insulator pins keeping them in place; when the wires are all drawn out the linemen proceed to stretch them up and tie them to the insulators.



Erecting a "Long Distance" Telephone Pole.

The poles are generally of live cedar or chestnut and are carefully selected so as to admit only the very soundest material. A special point has been made of using tall poles so as to carry the wires clear of trees and other wires; up to quite recently no poles less than forty feet long have been used on any line and in many places poles twice this length have been erected, sometimes for a considerable distance. It is a standing rule that the lowest wires of a long-distance telephone line shall clear all obstructions by at least six feet. The practice of using very tall poles, however, has lately been modified, as it has been found that a shorter, stiff pole gives better results; with a long pole the weight of the wires and cross-arms has so much leverage that in stormy weather the poles are liable to be either broken off short just above the butt or else torn clean out of the ground. It has therefore been decided to build new lines with poles thirty-five feet long, set six feet in the ground. The cross-arms are of seasoned pine, ten feet long, and are fastened to the poles by long-fetter drive bolts and securely braced by two iron braces. Each cross-arm carries ten split locust pins for pony glass insulators.

In building a line the greatest possible care is taken to have the spans as even as possible; the length of the span does not exceed 130 feet on a main line carrying fifty wires, and an even shorter span is made for a heavier line. On curves the regular span is departed from and poles are placed closer together, but as soon as the line is beyond the curve the regular spacing is returned to. No pole is placed immediately in front of a gate or driveway nor within ten feet of a pole belonging to any other line. Every detail of pole-setting receives careful attention. On the straight, poles are set at least six feet in the ground and on curves at least seven feet. The holes are dug large enough so that the butt of the pole can be dropped straight in without any forcing, and when the pole is in position only one shovel can be used to fill in, the earth being thoroughly tamped down with three iron tampers at every step until the hole is completely filled with solidly packed earth. Where the ground is too soft for proper tamping a grouting composed of one part of Portland cement to two parts of sand mixed with broken stone is used to make an artificial foundation. In medium soft soil the pole is braced up or anchored by means of two pine planks about eight feet long, which are bolted to the pole just below the surface of the ground and give it a firm bearing. At all curves the poles are thoroughly guyed or braced, head or side guys being used as the conditions demand. A special point is made of keeping the line as level as possible, that is, of avoiding abrupt changes of level in the wires themselves; to this end the height of the poles is proportioned to the contour of the ground, tall poles being placed in dips and valleys and short ones on knolls and eminences.

IV.

The securing of rights of way is quite an important part of laying out a long-distance line. It is of course highly necessary to ensure that the line shall be free from all risk of intentional interruption, and great care is taken to consult and secure the consent of all property-owners and municipalities wherever requisite. All of this is done in the most business-like manner, formal agreements and contracts being drawn up regarding every right of way secured. The Long-Distance Company also buys the right of trimming trees wherever the branches are likely to interfere with the lines; occasionally the trees have to be bought outright in order to trim them sufficiently or remove them entirely so as to render the lines perfectly safe. It is a rule that the branches of all trees near the line shall be trimmed so as to clear the wires by at least six feet. By attending to all these details with minute care the company renders its lines as safe as they possibly can be made, both as regards intentional damage arising from disputes with property-owners and accidental contacts with overhanging trees, which would give rise to serious disturbances.

At all points of junction between the overhead lines and underground or submarine cables the terminal pole is surrounded with special safeguards, which are rendered necessary on account of the pull of the wires being all in one direction. An extra pole is set within 30 feet of the terminal pole in order to make a short span, taking off a great deal of the strain from the terminal pole; this pole is head-guyed to the terminal pole. The terminal pole itself is side-guyed in both directions and also either head-guyed or braced; in this manner it is rendered capable of bearing all the strain thrown on it and is made practically as solid as a rock. At one time it was the practice to fit double cross-arms on the terminal poles and to tie the wires to the insulators on both cross-arms, but this has been abandoned as it was considered that the weakening of the pole through driving so many large bolts into it more than counteracted the advantage of the double cross-arms.

By adopting these thoroughly sound methods of pole line construction and building all lines on strict engineering principles the Long-Distance Telephone Company has built up a plant of overhead wires which both for sightliness and efficient working has no equal probably in the world, certainly not in the United States, where overhead construction generally is of the flimsiest and most rough-and-ready description. It must be borne in mind that in running a large number of telephone wires for a long distance on a single line of poles the company embarked in absolutely pioneer work. Where other very long telephone lines are in use they consist generally of a single circuit only, or at most two. The difference between operating one or two metallic circuit telephone lines and operating 10 or 20 or 40 on the same line of poles is very great indeed and is a point that generally escapes notice. Such confidence, however, was felt by the officers of the company in the success of the plans they had drawn up that the first line built, that between New York and Philadelphia, was equipped with 26 wires, sufficient for 13 metallic circuits.

This line was arranged acccording to what was then known or imagined about long-distance telephony. It was supposed that with carefully constructed metallic circuits perfectly quiet lines would be obtained. At that stage of the art this was a fair premise. It had been shown before that with a well-insulated metallic circuit there was no trouble from outside interference and such a thing as telephonic induction between different metallic circuits was not suspected. It is always the unexpected that happens, however, and in this case it was found that a number of metallic circuits run in close proximity to each other could be quite as troublesome as a number of grounded circuits, or even more so. When communication was established between the two cities it was found that conversation between New York and Philadelphia could be had with perfect ease, but the disconcerting fact presented itself that talking being carried on over one circuit could be plainly overheard on any other of the 12! The induction between wire and wire was so effective that it was quite practicable to carry on a conversation from one circuit to another. The plan of transposing the circuits in the middle of the line was tried and although some slight difference was noticed the evil was still almost as great as at first and it was found quite impossible to open the line to public service until the problem of telephonic induction between metallic circuits had been satisfactorily solved and a corrective applied.

V.

This was done by undertaking an exhaustive series of practical experiments with a view to discovering the manner in which the disturbance was caused and the share of it which might be attributed to the different elements of the circuit. Naturally, transmitters, receivers, induction coils, and switching apparatus came in for thorough investigation, but the line was the object of most searching attention. Almost every conceivable scheme of transposition was tried, and the wires were twisted and crossed in all manner of ways so as to give every plan a complete experimental trial. Finally the remedy was hit upon by transposing the wires so as to make the relative exposure between the various circuits the same throughout the line. This is much more of a piece of work than it sounds. Of course under ordinary circumstances the wires of an overhead line preserve the same relative position throughout the line. But the relative exposure of one wire of a metallic circuit to the others, of course, differs, as the exposure is greatest between neighboring wires and least between the wires that are furthest separated from each other. It is obvious, then, that to give each wire of a circuit the same effective average exposure to every other circuit in the line materially complicates the work of overhead construction. This arrangement, however, was found necessary in order that the inductive disturbances set up between the different circuits should completely balance and neutralize each other. When this plan was adopted and systematically carried out, the cross-talk, which at first was so extremely plain that it appeared unconquerable, was completely overcome and eradicated.

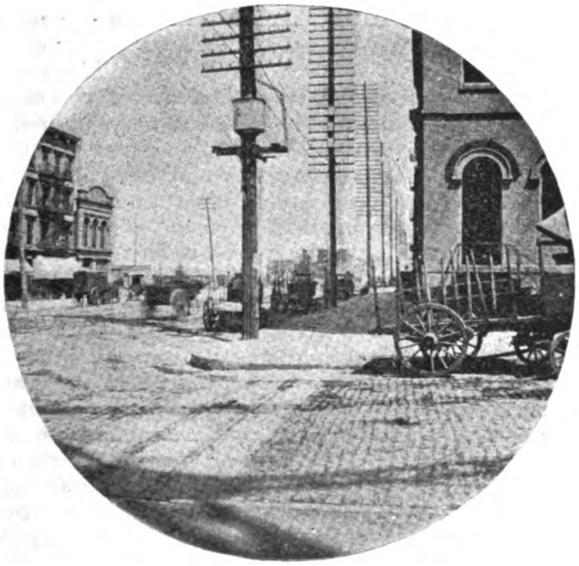
This method of transposing the circuits involves, of course, the preparation of a separate scheme of transposition for every line, the design of which depends on the number of circuits that the line is to carry and the length of the line. All this has to be carefully laid out before the building of the line is begun, as the directions referring to transpositions form an indispensable part of the specifications. Transposition poles are determined at regular intervals along the line. These poles are provided with special double insulators devised for the purpose of facilitating the change in the position of the wires where transpositions are made. The transposition insulator consists of two insulators threaded on the same pin. The lower insulator has a hole through the top and the pin extends up through it; the upper one is then threaded on the top of the pin, a good space being left between the two insulators. In order that the ordinary pins may be used for the double insulators, a threading tool has been devised for turning down the lower part of the pin to the required dimensions. When a circuit is transposed, the left-hand wire of a pair is brought to the upper insulator and then extended parallel with the cross-arm behind and around the upper right-hand insulator. The right-hand wire of the pair is taken to the lower insulator and then behind and around the lower left-hand insulator. The wires are tied to each insulator in the usual manner. The transposing of the wires is done in this manner during the construction of the line without cutting the wires, and the linemen have become so expert in this method of running wires that no difficulty is found in keeping up the standard of construction in spite of the complications introduced by transposing the wires at frequent intervals. When existing circuits have to be transposed the wires are dead ended at each of the four insulators, and the transpositions are made by connecting short pieces of insulated wire which are drawn tightly across the two wires to be transposed.

The transposition poles are set at intervals of 1,300 feet, or four to the mile, on all lines, but only a certain number of the circuits are transposed at each pole. When a circuit is transposed the relative position of the two wires which compose it is reversed, and this renders it neutral to certain of the other circuits on the line. At another pole other circuits are transposed and the process is kept up until neutrality is obtained between all the different circuits. The scheme of transpositions, of course, becomes more complicated as the number of circuits of which the line is made up increases, and the arrangement of the transpositions for a long line containing a large number of circuits is no simple task.

VI.

The twenty-six-wire line to Philadelphia having been brought to successful operation and the feasibility of long-distance telephony over a line containing a large number of circuits completely vindicated, further extensions of the system were made eastward from New York, through the New England States. The Philadelphia line was of the nature of a bold experiment, but so much valuable information was derived from it that in building the line to Providence and Boston the company planned its operations on a much more ambitious scale. The experience already gained showed conclusively that the most important factor of the entire system was the line. If the electrical conditions of the line were favorable no particular difficulty could be apprehended in providing efficient transmitters, receivers and operating apparatus. To secure favorable electrical conditions, apart from the scientific arrangement of the line for neutralizing inductive disturbances already described, the very highest grade of construction was absolutely necessary. This was adopted in the beginning and has been consistently adhered to throughout. The second great advantage which arises from the adoption of a high standard of line construction is the trustworthiness of the service, which is one of the most salient features of the long-distance system.

The maintenance of the long-distance telephone lines excels that of any known system of overhead electrical communication in the world. When the company started to build their main lines from New York to Boston and other New England towns a pole line was constructed to carry eighty wires, and this number of wires continued on a single line of poles for a distance of fifty miles out of New York. Telegraph men smiled and scoffed derisively, declaring that it would be impossible to talk without interferences over such a line to begin with, and further, that it would be impossible to keep all the wires in order for a single day. The line worked perfectly, as the system of transpositions devised for it took care of all inductive disturbances. As for the maintenance, the records show that on about two hundred days of the year not a single trouble occurs on any of the wires. It will be granted that for four thousand miles of wire this is a pretty good record and one that it would be hard to beat. One of the main lines between New York and Boston has forty wires, and the maintenance record of this line is equally good. During the severe storm which prevailed through the first four days of March of this year the ten thousand miles of wire contained in this line remained absolutely intact, without developing a single trouble of any sort. Such practical results as these show conclusively the value of paying the utmost attention to all details of line construction and maintenance.



A Long Distance Telephone Line in New York City.

Patroling the Long Distance Lines During the Great Blizzard, March, 1888.

It is well known that owing to the stable character of the long-distance lines the company is always able to give telephone service at times when the telegraph is hopelessly crippled. There have been many instances of this during the past few years; probably the most notable one was afforded by the famous blizzard of four years ago. For several days after that phenomenal storm the only direct communication with points outside of New York was had by means of the long-distance wires, and while telegrams between New York and Boston had to be sent via Ireland through the Atlantic cables, conversation by telephone was carried on between the two places with the same ease and regularity as during ordinary times. On many occasions since then the long-distance telephone wires have stood the business community, the newspapers and the railways in good stead, as the storms which play havoc with the telegraph lines seldom succeed in doing any serious damage to the stout poles and tautly drawn copper wires of the long-distance telephone system.

VII.

After having extended the system through Connecticut, Rhode Island and Massachusetts, providing several independent routes between New York and Boston, lines were built up into Vermont, New Hampshire and Maine. Next a main line was built up through New York State through Albany, Troy and Syracuse to Buffalo. Other lines were extended through the central part of the State and through Pennsylvania and New Jersey, joining all the principal manufacturing towns in the general system of communication. Southwest, lines were built to Baltimore and Washington, and finally operations were pushed directly westward through Pennsylvania and over the Alleghenies to Pittsburgh and Cleveland. Up to quite recently the line between New York and Buffalo was the longest telephone line used for regular commercial service in the world, the length of the circuit being about 450 miles. Direct communication is now often called for between Boston and Pittsburgh via New York, the circuit measuring over 600 miles and containing several miles of underground and submarine cable. The transmission between Boston and Pittsburgh is perfectly good, in spite of the great length of the circuit. By way of showing that the long-distance telephone system is capable of even greater feats than this, communication was recently had between Newark and Boston over a circuit upwards of a thousand miles long. This circuit was made up by connecting together wires going through Philadelphia, Pittsburgh, Erie, Buffalo and Albany; the experiment was thoroughly successful, as conversation was maintained over this extremely long line without any difficulty whatever. In view of such results as these it may reasonably be expected that by the opening of the World's Columbian Exposition Chicago and New York will be in direct telephonic communication.

VIII.

Although overhead wires of course make the most favorable line for telephonic transmission, owing to their low inductive capacity and comparatively low resistance in carrying a line across country and through cities, certain lengths of submarine and underground cable necessarily have to be included in the line. Wherever it is possible to do so, underground work is avoided, as a very short length of underground cable suffices to cut down the transmission to a great extent. This can readily be understood when a comparison is made between a line having a resistance of 5.25 ohms and a capacity of .015 microfarad to the mile and one having a resistance of 44 ohms and a capacity of .08 microfarad to the mile. Telephone cables have been greatly improved during the past few years and the inductive capacity has been lowered to a point that would have been considered impossible when the wires were first put underground. Three years ago the average capacity of the wires was .18 microfarad per mile; to-day underground cables are made containing one hundred wires in a pipe 1.875 inch in diameter with an average capacity of only .075 microfarad per mile. With all the improvements that can be made, however, underground cables must always constitute a serious obstacle to long-distance telephony. The only places where these cables must be used are the large cities, such as New York, Boston, Philadelphia and so on. The junction between the overhead lines and the underground cables is made generally on a pole, the cables being led up the pole and headed up in a tower consisting of a railed platform for the men to work on and a weatherproof box for the protection of the cable heads and lightning arresters. Insulated bridle wires are jointed to the overhead wires and cleated in regular order along the cross-arms to the pole which they follow down into the cable box where they are connected to the lightning arresters. The arresters are so arranged that the fuses can be removed for testing the line in either direction when tracing out troubles.

Submarine cables are even more objectionable than underground wires, because the waterproof insulation used for protecting the conductors has a much higher inductive capacity than the paper or cotton insulation used in underground cables. The capacity of a single mile of submarine conductor is about equivalent to that of twenty miles of overhead wire. Submarine crossings occur pretty frequently in the long-distance system, but fortunately the cables are seldom more than a few hundred feet long; the longest crossing is that of the Hudson River at New York City, where the cables are almost exactly a mile long. The plan of twisting the conductors in pairs to prevent inductive interference between the different circuits which has been so successful in underground cables, cannot be followed in the manufacture of submarine cables with rubber-insulated conductors on account of mechanical difficulties, but a special form of cable has been designed by the engineer of the Long-Distance Company in which the conductors are laid up in groups and the groups afterwards stranded together; this makes a convenient and compact arrangement of submarine conductors. The cables are led into small cable houses on each side of the river in which they are connected up to lightning arresters of improved design. The overhead lines terminate on a terminal pole just outside the cable house, and insulated bridle wires are jointed to the line wires and run down into the cable house and there connected to the line side of the lightning arresters. Periodical tests for insulation and copper resistance and inductive capacity are made on all cables belonging to the Long-Distance Company by members of the engineer's staff.

A style of cable which is peculiar to the American Telephone and Telegraph Company is that called "emergency cable." This is made up of fourteen waterproof insulated conductors twisted in pairs and laid up round a core of steel wires stranded together. The cable is served with an outer protection of tape impregnated with compound. This emergency cable is very strong and can be laid in almost any position, over housetops or strung upon the stumps of broken poles, or along the ties of a railway. Thirty miles of it are kept always in stock by the company for prompt temporary repairs of any line that may be interrupted by a fire or a storm of extraordinary violence. The cable is stored on reels which hold 1,500 feet each; these reels are designed to be taken in a combination baggage car so that they may be quickly sent to the scene of action, and a certain number of them are kept in readiness at various points in the system.

LEAD-COVERED CONDUCTORS.

The substitution of lead instead of zinc for coating or galvanizing conductors is advocated in an article in *L'Electricien*. Zinc has certain disadvantages—tendency to form an alloy, high melting temperature and tendency to flake. Lead seems to be preferable for certain reasons, and its application is similar to that of zinc. The objects are cleaned electrically, and immersed in an aqueous solution containing 10 per cent. of hydrochloric acid and 1 per cent. of hydrofluoric acid, heated to 50° C. in a vessel coated with lead. They are connected to one pole of a dynamo as anode, the lead coating constituting the other pole. After this preparation they are dipped into limewater of the same temperature, and then into an alloy of equal parts of zinc and tin in hydrochloric acid, which greatly favors the adherence of the melted lead into which they are then dipped. The process is economical and is not confined in its advantage to iron or steel articles, but may be used for chemical and electrolytic vessels. The iron or steel wires serving as protection in armored cables, it is suggested, might be advantageously treated by this method in preference to the ordinary galvanizing process.

"MUST HAVE IT."

The superintendent of the Haverstraw Electric Light Co. writes us: "I can hardly do without The Electrical Engineer. I have taken it for three years and have received from its pages much help and edification."

THEORETICAL ELEMENTS OF ELECTRO-DYNAMIC MACHINERY—III.[1]

POTENTIAL DISTRIBUTIONS.

THE case in which the magnetic equipotential surfaces are parallel, equidistant planes is of considerable importance, on account of its geometrical simplicity and also of its practical applications. The gradient being everywhere equal and in the same direction, *B* is everywhere equal in intensity and normal to these planes within the limits of the distribution. This condition is termed a uniform field, and must necessarily be confined to limited portions of any magnetic circuit, when it is considered that all flux lines are closed curves, and cannot follow straight lines for even one-half of their total circuital length. On the other hand, even the most irregular and sharply curved fields can be divided into so great a number of small elements that each may be considered separately as a uniform field. The earth's magnetic field represented over the surface of a small model globe would appear to be far from uniform, but on the actual scale uniformity appears to exist, and *B* is constant (at any one moment, beyond the range of iron or iron ore) within several hundred feet of any locality so far as the most sensitive instruments can discern.

A uniform helix of wire was named by Ampere a solenoid. Strictly speaking the term only applies to a series of equal and parallel conducting rings arranged in close successive order round a common axis, but the difference between a closely wound spiral and the hypothetical arrangement is usually negligible in action. The field within an infinitely long solenoid carrying a current is uniform, the equipotential surfaces being planes normal to the axis, and dividing the interior of the solenoid into equal compartments.

If c be the C. G. S. current circulating in the solenoid, and n the number of turns per centimetre of length, nc will be the current turns per unit of length, and the distance between the successive integral equipotential planes will be $1/4 \pi nc$ cms. The gradient being one erg in this distance, its representative, the flux, will be $1 + 1/4 \pi nc$, or $4 \pi nc$ units of flux per square centimetre, and if the cross sectional area of the solenoid be a square centimetres, the total flux within it will be $4 \pi nca$.

While theoretical uniformity of field would only be attainable within an infinite solenoid, a very close approximation to uniformity is secured from solenoids of convenient practical dimensions if their length is great compared with their diameter. The flux becomes divergent in such cases towards the extremities, and as the length of the helix is reduced, the limits of practical uniformity are retracted and narrowed to the centre of the coil. The flux emerging from the extremities completes the external circuit by indefinitely extending contours.

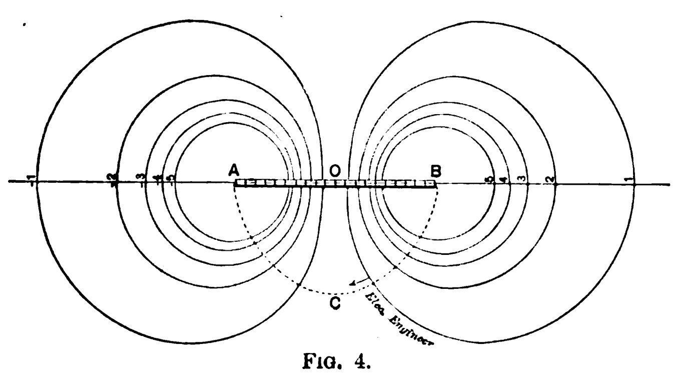

FIG. 4.

Fig. 4 represents a plane section through the axis of a solenoid A O B, and the ovals are the traces of a few of the equipotential surfaces that govern the external flux. If these could be rotated about the axis A O B a dumb-bell-shaped system of equipotential envelopes would be formed. The length A B being taken as 100 cms., and the C. G. S. current turns 100 per centimetre, the successive integral surfaces would be represented to scale from 5 ergs positive to 5 ergs negative, the central plane through O C, normal to the axis, being that of zero potential. The sectional area of the solenoid is also assumed to be one square centimetre for convenience. The flux is always at right angles to these surfaces on its passage down grade from B to A as indicated by a single dotted line A C B taken as one path at random out of the infinite number possible. Within the solenoid, the surfaces are very nearly planes, and the field very nearly uniform from the centre O to within ten diameters of the ends.

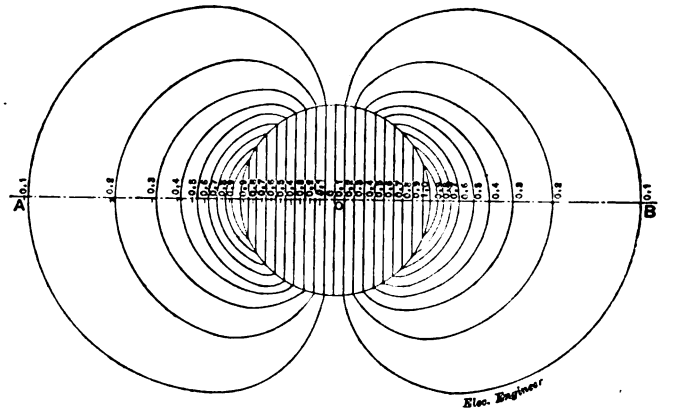

FIG. 5.

Another form of conducting surface which produces a uniform field within the entire space it envelops is Maxwell's ellipsoid. If an ellipsoid be divided into slices by equidistant planes normal to one of the axes, and the surface between each consecutive pair be uniformly wound with the same number of turns of conductor, so that the current turns round each slice are equal, the field within the ellipsoid will be uniform. The proposition applies to a sphere as a particular case. Fig. 5 represents a plane section through the centre of such a sphere and gives the traces of a few equipotential curves. The diagram if revolved about the axis A O B would generate a system of equipotential surfaces forming planes within the hollow sphere, and spheroidal envelopes external to it. If the diameter of the sphere be 20 cms. and the surface be wrapped with ten turns of wire per centimetre of axis, making 200 turns in all, a current of 0.002387 C. G. S. will establish to scale the surfaces represented; and generally, if nc be the current turns per axial centimetre, the potential of any plane through the sphere parallel to the windings, distant x centimetres from the centre, will be $\frac{4\pi}{3} ncx$, a value independent of the diameter of the sphere. The gradient will then be $\frac{4\pi}{3} nc$ ergs per cm. and this will be the value of *B* everywhere within the sphere.

This case of the uniformly wound ellipsoid seems to be the only one yet known that will produce throughout the interior of a conducting surface having any assigned finite magnitude a perfectly uniform field. The geometrical difficulties in the way of its accurate practical construction appear to have excluded its application from the purposes of measurement.

It is curious to observe that while in Fig. 4 there is an absolute discontinuity at the surface of the solenoid between the internal and external potential surfaces except at the centre o where the zero planes coincide without and within, in Fig. 5, at the surface of the sphere there is a discontinuity of direction only, and a continuity of numerical value. The surface continues with a sudden change in shape.

---

We have defined the potential as that quantitative property of a point in space, whose gradient is the vector flux intensity. There is, however, another and useful point of view from which the conception of potential can be regarded, and which has in reality prior claims to consideration so far as regards the historical development of the subject. The definition which follows can, however, be readily proved to be involved by, and equivalent to, the preceding.

The magnetic potential at any point, due to any magnetic body or system, is the work which would have to be mechanically performed solely against magnetic forces, in conveying a free unit north pole from an infinite distance up to that point, assuming that no other magnetic forces are active on the pole during the journey except those exerted by the body or system considered.

In other words, the potential of a magnetic element or system at a point is the potential energy between that system or element and a free unit north or positive pole there deposited; for, if left free to move in obedience to magnetic forces, the pole would commence to retreat and develop kinetic energy that would find its complete value in a culminating velocity only after having receded to an infinite distance. That final kinetic energy would be the potential of the starting point. That is on the supposition that the potential of the point was positive. If, on the contrary, the potential had been negative, the $+$ pole would not have retreated, but would have absorbed work, *i. e.*, developed negative energy during the passage; it would have been attracted by the body exercising potential influence and not repelled.

As a consequence of this relation, it is evident that if we move our ideal free north unit pole from a point whose potential is, say, 50 ergs $+$, to one whose potential is $+$ 75 ergs, we shall have to expend 25 ergs of energy in the process. The energy will be stored in the system potentially, and will be liberated on a return journey. The amount of energy is independent of the path selected between the points, provided that it is not linked with any current or magnet, or in other words that the path could be drawn tight into a straight line without cutting through any current or magnet. For if a rectilinear path expended 25 ergs, while another course diverged to execute one complete turn, in addition, round some current of c C. G. S. units, the work done in this passage would be $25 \pm 4 \pi c$ ergs, the sign depending on the direction of circuitation and of this current.

Also it is evident that no work would be expended magnetically on, or by, a pole constrained to move exactly over an equipotential surface. Whatever energy might be exchanged between the pole and its environment under those conditions would be altogether independent of the magnetic system, and would take place equally if that system had been suppressed. On this account a pole does no magnetic work in directly approaching or leaving an infinite rectilinear current alone in space, and a long straight current-conveying wire does not attract a magnet, for we have seen that the motion would be confined to some equipotential plane. But work would commence to be done, and energy commence to enter or leave the magnet so soon as the latter departed from the straight line of approach, and moved round the wire.

Mr. Frederic Nicholls, who is so largely identified with electrical interests in Toronto, has been elected to the presidency of the Athenæum Club of Toronto, a social and athletic organization of high order. The club has built itself a new house, which opened with great *eclat* on April 4.

RECENT IMPROVEMENTS IN QUADRUPLEX TELEGRAPHY.

BY

William Finn.

Numerous attempts have been made in the past to increase the efficiency of quadruplex circuits by the introduction of certain devices having for their principal object the neutralization of the "kicks" produced upon the neutral relay by the reversals of the distant battery. Many of these devices have been more or less successful in operation, though none can be said to have proved entirely acceptable under all conditions of working.

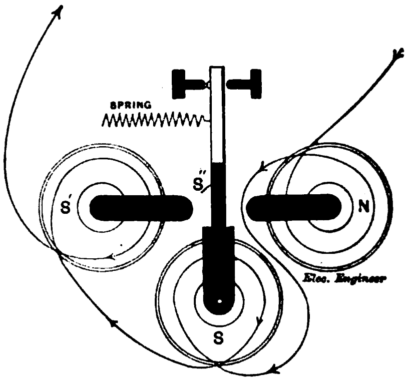

Fig. 1.—Freir Self-Polarizing Relay.

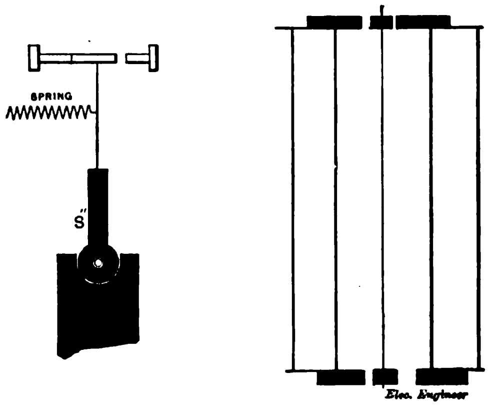
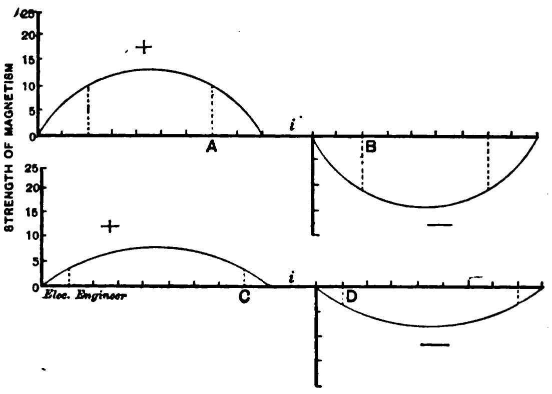
A relay has been recently invented by Mr. Samuel P. Freir of the Western Union Telegraph Co., in this city, which entirely obviates the necessity for any of those adjuncts, which have heretofore formed so conspicuous a feature of every long quadruplex circuit. The apparatus is called a self-polarizing relay, and consists essentially of three coils, Figs. 1, 2 and 3, one of which, S, is in connection with and magnetizes a soft iron armature S'', whose induced polarity alternates with every change in the direction of the received current. The other two coils N and S', respectively, attract and repel the armature, which merely responds to the "increase" of the distant battery, by moving in a certain direction only, regardless of the changes in the direction of the current. This will be apparent by referring to Fig. 1, which shows the winding of the coils to be such that the nature of the magnetism induced in the repelling coil on the left, together with that induced in the centre, or armature coil, is alike, but opposite in polarity to that created in the right-hand or attracting coil.



Figs. 2 and 3.—Freir Self-Polarizing Relay.

The success of the apparatus depends apparently upon its small "time constant"; or, in other words, upon the property it possesses of becoming actively energized by the exciting currents when they acquire a strength less in amount than that which they ultimately attain. It has no iron yoke like other relays, and the mass of its cores is otherwise diminished; so that the iron receives, and parts, with its magnetism very readily. The magnetism developed is comparatively feeble, though of sufficient intensity to affect the light moving parts of the instrument, without generating those strong counter E. M. F.'s in the coils, which in other relays retard the growth and decay of the incoming currents. The "interval of no current," which has been more or less regarded as the bugbear of the quadruplex system, is almost imperceptible in this relay; which strengthens the belief that the said interval has not in reality played so detrimental a part in the operation of quadruplex circuits as has been generally supposed. It would appear, on the contrary, that the high self-inductive property of the neutral relay has been the main cause of its inefficiency.

In a relay of considerable inductance, the magnetism developed at the very commencement of a current is of comparatively small value, owing to the retarding effects of the counter E. M. F.'s previously mentioned. Some time must, therefore, elapse after the current has been started, before the magnetization excited gains sufficient strength to attract the armature against the strong antagonistic force of its spring; and just as soon as the magnetism falls below that same value, the spring will tend to pull the armature away from the cores again. The period during which the armature will remain attracted by a current will evidently be augmented should the relay become responsive, when the magnetic intensity acquires a comparatively low figure. The interval of no current will then be so small compared with the length of time the current will remain *effective*, as to be hardly noticeable on the relay.



FIGS. 4 AND 5.

This appears to be the secret of the success of Mr. Freir's relay, the superiority of which over that of other relays will be better appreciated from a study of Figs. 4 and 5. The horizontal lines are divided into equal divisions of time, and the continuous vertical lines into equal increments of magnetism. The curved lines represent the gradual rise and fall of magnetism due to the corresponding variations in strength of the exciting currents; while the dotted vertical lines indicate the relative degree of magnetic intensity at which each relay becomes active. The armature of the neutral relay in Fig. 4, for instance, is supposed to become attracted when the magnetism reaches a strength of 10, whereas the Freir relay, Fig. 5, becomes actuated at a magnetic strength of about 4. The distances between A and B, and C and D, respectively, represent the length of time each relay remains *inoperative* during a complete reversal of the current, the interval *i* of no current being the same in both cases.

It is quite certain that much advantage is to be gained, by reducing, as far as practicable, the electromagnetic inertia of the receiving apparatus on long quadruplex lines of high inductive capacity. The writer has experimented in this direction with some measure of success on the common neutral relay, by magnetically insulating its iron yoke A, and making it adjustable with regard to the cores, as shown in Fig. 6. This arrangement admits of the armature B being placed (permanently or otherwise) in close proximity to the cores, without the least tendency on its part to "stick." The number of magnetic lines that may be forced across the air spaces, and through the armature, can be regulated to suit the varying conditions of the line, by simply moving the yoke A further from the cores in fine weather when the current is strong, or by bringing it up when the weather is bad and the current weak. The self-induction of a relay constructed on this principle is comparatively low, its cores charge and discharge rapidly, and, since there is little or no remanent magnetism after the cessation of the current, the received signals come clear and distinct. The number of convolutions on such a relay should be greater than in the ordinary case, in order to exalt the magnetic effects, which, owing to the high reluctance of the magnetic circuit, are greatly diminished, especially in wet weather.

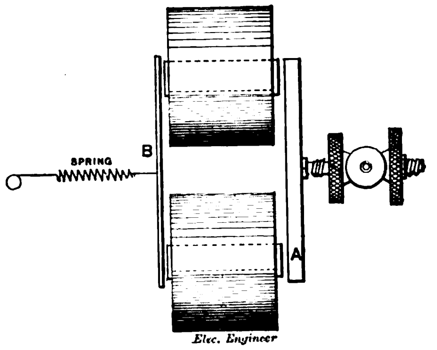


FIG. 6.—FINN NEUTRAL RELAY.

The Freir relay has, however, proved highly satisfactory under nearly all conditions of working, and is rapidly supplanting the older form of relays throughout the Western Union service.

It is not to be inferred, however, that the final stage in the development of the quadruplex system has yet been reached, and devices for remedying certain other defects, both great and small, which still exist, are continually turning up.

One of the latest and most successful of these is an invention by Mr. O. K. Newton, of the Western Union, for suppressing "sparking" at the points of the pole changer, and which, incidentally, also diminishes the interval of no current. This is accomplished by interposing a resistance of about 1,500 ohms in the circuit for a brief period immediately after *direct* contact with the battery has been broken. The extra current of self-induction, instead of darting across the air space between the points P P of the relay is diverted through this resistance, as will be seen by referring to Fig. 7.

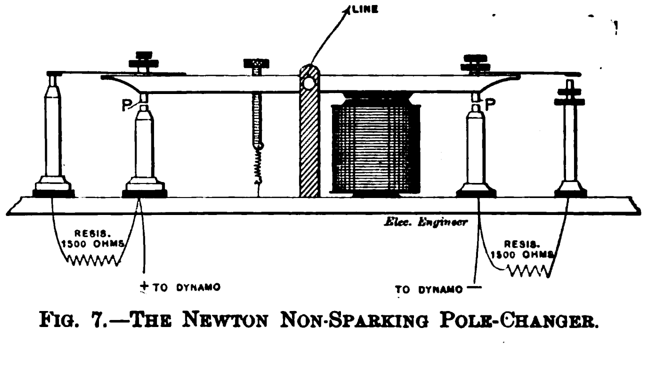

FIG. 7.—THE NEWTON NON-SPARKING POLE-CHANGER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

VOL. XIII. NEW YORK, MAY 4, 1892. No. 209

It has been proved pre-eminently in America that the mind and hands can be trained at the same time and without prejudice to either.—Coleman Sellers.

THE ELECTRICAL ENGINEER has removed its offices to the fine new *Mail and Express* building, Broadway and Fulton Street.

The address is 203 Broadway.

MUNICIPAL LIGHTING PLANTS IN OHIO.

THERE has been a general supposition that New England was the region in which the idea of municipal electric light plants had made the most headway, but it would appear that Ohio has the craze about as badly as any other part of the Union. Not only have efforts recently been made to establish municipal plants in Cleveland and Cincinnati, but at the present time ten towns have been authorized by the Legislature to submit the question to popular vote. Berea, with 2,500 inhabitants, wants to issue $18,000 of bonds; Medina, the same; Niles, with 4,300 people, is spending $15,000 on electric lights and waterworks; Mt. Gilead, with 1,400 people, is to spend $20,000 in electric lights and roads. Napeleon, population 2,800, is to vote on $60,000 for electric lights and waterworks; Chicago Junction, 1,300 population, wishes to spend $25,000 on a village plant; Wapakoneta, with 3,600, votes on spending $20,000: West Liberty, with a bare 1,000 people, is to vote on $15,000 of bonds; Germantown, with less than 1,500, is to appropriate $10,000; and West Milton, with a mere trainload of people—850—is to raise $25,000 by bonds for a town hall and electric lights.

One can have no fault to find with the desire for, and high estimation of, the electric light thus evinced; but it remains a matter for regret that so many communities should be ready to burden themselves with heavy debt and taxation to secure doubtful returns.

LIGHTING WITH HIGH FREQUENCIES.

THE cable dispatch which appeared in our columns several weeks ago gave the first details in this country of the experiments in the lecture delivered by Mr. Tesla in London. Though necessarily brief in outline, it, nevertheless, gave sufficient indication of the fact that the lecturer had already made a decided step beyond the results brought by him before the American Institute of Electrical Engineers nearly a year ago. With the full text of Mr. Tesla's London lecture before us, as issued by the London Institution of Electrical Engineers, the opinion expressed at that time is more than confirmed, as we have a remarkable exemplification, in all directions, of the various lines of work undertaken by Mr. Tesla. He has, however, dwelt more particularly on one or two points which are pertinent at this time, in view of the fact that recent experimenters, among them Siemens, have attempted to show that the results obtained by Mr. Tesla could also be achieved at much lower frequencies than he employs. On this point Mr. Tesla placed himself on record by admitting that some of his experiments may be performed at low frequencies, but he held that very high frequencies are desirable, not only on account of the many and enhanced effects secured by their employment, but because by their means it is convenient, in turn, to obtain the necessary high potentials required for this work. He also points out that with lower frequencies the coils required are very much larger than would otherwise be necessary, so that on the score of commercial economy alone, if on no other, high frequencies are desirable.

Mr. Tesla also described a variety of apparatus for obtaining rapid disruptive discharges, in which he included the use of both an air blast and an electromagnetic blast to blow out the arc formed between the knobs. In these experiments with a peculiar discharger consisting of multiple gaps, Mr. Tesla touches very closely on the recent work of Mr. Alexander J. Wurts, and throws light on the results obtained by the latter gentleman. Thus Mr. Tesla shows that the dielectric strength of a given total width of air space is greater when a great many small air gaps are used than with a single one; and that the working with a smaller length of air gap results in a smaller loss and less deterioration of the metal of the knobs. Again, by the splitting of the arc into smaller ones, the polished surfaces last much longer. Mr. Tesla also shows that the sparking distance is much diminished as the frequency is increased.

Another important argument in favor of the employment of high frequencies is brought out by Mr. Tesla in experiments which prove to him that in the search for novel methods of producing light by an agitation of the atoms or molecules of the gas we need not limit our researches to the vacuum. He looks forward quite seriously to the possibility of obtaining the light effects without the use of any vessel whatever, with air at ordinary pressure. Thus Mr. Tesla, with his experimental coil, has been able to produce a strongly luminous sheet, covering an area of more than one square meter between wires placed in the ordinary atmosphere. Oil insulation has also, of necessity, forced itself upon the attention and claimed the study of Mr. Tesla, who advocates its use; and he believes that our future distributions of electrical energy and high tension currents will be effected by the aid of liquid insulation.

In his Columbia College lecture Mr. Tesla exhibited a variety of forms of lamps operated by means of one and two wires, as well as without wires, and his later researches have led him to a still greater variety in this respect. His latest efforts seem to be in the direction of concentrating as much energy as possible upon a refractory body of small size, and heating this together with the surrounding atmosphere to the highest possible incandescence. Of all the bodies experimented with, the "carborundum" of Mr. E. G. Acheson seemed to give the best results. With buttons of this material, the blackening of the globe is very slight, which suggests to Mr. Tesla its employment as a coating for the filaments of ordinary incandescent lamps. This material, however, does not phosphoresce, and thus follows the general law that conductors cannot phosphoresce. This leads Mr. Tesla to inquire what there is in such a body as a metal, for instance, that deprives it of the quality of phosphorescence. He reasons that it is quite possible that at some extremely high frequency, when behaving practically as a non-conductor, metal or any other conductor might exhibit the quality of phosphorescence, even though it be entirely incapable of phosphorescing under the impact of a low frequency discharge. Mr. Tesla points out in this connection that the high incandescence of the electrode is not the only result to be striven for. The more important factor is the high incandescence of the gas surrounding the button, by which means a far greater economy is obtained, and owing also to the fact that with a surrounding atmosphere the button is comparatively relieved. To obtain these effects Mr. Tesla finds it preferable at high frequency to employ only one electrode and one connecting wire. He also affirms his conviction that the illuminating device of the near future will not require for its operation more than one lead, and at any rate will have no leading-in wire, since the energy required can be transmitted through the glass.

On the question of personal safety in the operation of such appliances Mr. Tesla considers that there are two ways of rendering an electric appliance safe. One is to use low potentials, the other is to determine the dimensions of the apparatus, so that it is safe, no matter how high the potential is used. Still another reason why high frequencies are desirable is to be found in the fact that, the higher the frequency the slower would be the exchange of the air in the vicinity of the incandescent electrode, and hence the less the loss of energy. Mr. Tesla believes, indeed, that a frequency may be reached at which there would be no exchanges whatever of the molecules around the terminal. It would, in fact, be a rigid flame, and Mr. Tesla believes that contrary to what might be supposed, these effects may be obtained with comparatively low frequency. He was even able to obtain some results of this nature with frequencies as low as ten thousand per second.

To dwell upon the many points elaborated by Mr. Tesla would lead us far beyond the limits of our space, but the descriptions by Mr. Tesla, the reasons which led him to the construction of his various types of apparatus, the application of his deductions to the explanation of many electric and magnetic phenomena in nature, all furnish an instructive and fascinating continuation of a work, the first chapter of which was brought out at Columbia College last year.

THE EDISON INCANDESCENT LAMP LITIGATION.

More than twelve years after the issue of Edison's fundamental patent, and seven years almost to a day, after the commencement of legal proceedings by the Edison Electric Light Company against the United States Electric Lighting Company, the beginning of the end in the long-protracted incandescent lamp litigation has been reached. The case having been decided in the Circuit Court in favor of the Edison Company, the United States Company carried the case to the Circuit Court of Appeals, which tribunal now has final jurisdiction in all patent cases, and on Wednesday of this week, after eight days of argument by the ablest counsel of the land, the case goes to Justices Lacombe and Shipman for final decision. Summed up in brief, the contention of the complainant is, that to Edison the world is indebted for the art of incandescent electric lighting, and that the most essential instrumentality of the art, the high-resistance carbon lamp, is covered by the patent sued upon. The contention of the complainant, on the contrary, is that whatever Edison may have invented, the particular patent sued on neither describes nor covers the invention in controversy, and moreover, that the complainant, having delayed for many years to commence suit, during which time the defendant had invested large amounts of money in the business, should at least be required by the court to permit the defendant to continue the manufacture of lamps upon the payment of a reasonable royalty. We regret that the pressure upon our columns precludes the possibility of presenting more than the briefest outline of the arguments which have been presented by the able counsel on both sides.

THE TELEPHONE PATENTS.

It is now some months since the issue of the Berliner microphone patent gave rise to a great amount of newspaper discussion, of a character which, to say the least, was much more vehement than enlightening. A contributor to The Electrical Engineer, in commenting upon the matter at the time, took occasion to express a conviction that, as he aptly phrased it, the much-sought-for Ethiopian was concealed in an entirely different part of the wood-pile from that which was just then being so industriously overhauled, and to venture a prophecy that the controlling patent would ultimately turn out to be that of Edison. The expected issue on May 3, of a patent to Edison upon an application originally filed so long ago as July 20, 1877, shows that our contributor was right in his conjecture. Whether the proceedings which have kept this application pending in the Patent Office for fifteen years, have been conducted throughout in absolute good faith, is a question which, in the absence of definite information it would be premature to discuss, although there is already plenty of discussion on the subject.

ELECTRIC RAILWAY POLE LINE CONSTRUCTION.

BY

W. F. D. Crane, M. E.

Part I.—Iron Poles.

A noteworthy feature in the building of electric street railways in cities at the present time is the tendency toward construction of the most substantial and permanent character. Iron has almost universally superseded wooden poles; and the "extra strong" and more expensive pole is rapidly superseding poles of less strength and suitability. The reasons are apparent. A weak pole strained up to, or beyond its elastic limit, has no margin of strength to withstand accidents incidental to overhead construction. On the other hand a broken span wire is less expensive than a bent or broken pole.

In view of these facts and the growing demand for the heavier poles there is reason to believe that poles which shall be standards of use for streets of ordinary widths will be of "extra heavy" pipe and of the following dimension:

5 in., 4 in., 3 in. pipe 27 to 28 ft. long for streets from 30 to 40 ft. between curbs.
6 in., 5 in., 4 in. pipe 27 to 28 ft. long for streets from 40 to 60 ft. between curbs.
7 in., 6 in., 5 in. pipe 28 to 30 ft. long for ordinary pull-off poles.
8 in., 7 in., 6 in. pipe 28 to 30 ft. long for extraordinary strains.

There is a difference in the amount of tension put upon the span-wire. Some engineers prefer a comparatively weak pole with span-wire at low tension and deep sag; thus saving something in first cost but losing in sightliness of the line. Better practice, however, dictates a tightly strung span-wire with not more than nine to twelve inches sag and the use of strong, stiff poles strained within three to six inches of the elastic limit and abundantly able to meet accidental strains incidental to the carrying of guard, span and feeder wires.

Side poles are usually buried six feet in the ground and set in concrete or ballast from four to six or more inches thick around the butt. Pull-off and strain poles are usually buried from six to seven feet, depending upon the character of the soil, and reinforced by substantial concreting, ballasting or the judicious use of large stones. A suitable concrete is made from one part cement and three parts sharp sand, thoroughly mixed with stones not larger than goose-eggs. The rake away from the street, to be given iron poles will depend upon the character of the soil, width of street, weight of trolley line and fixtures, and the margin allowed for the elastic limit, and will vary from six to twelve inches according to the conditions.

Centre poles on straight streets, not being subject to severe side strains, may be advantageously made of lighter pipe, 5 in., 4 in., 3 in., and 6 in., 5 in., 4 in., standard weight, from 26 to 27 ft. long being common sizes, buried five feet or more in the ground. When the line follows the windings of streets and the poles are subject to side strains, heavier poles become necessary; a 6 in., 5 in., 4 in. extra strong pipe pole guyed at head and arms, diamond-guyed at intervals, answering most purposes. Centre poles when situated in the open street, should invariably be provided with wheel guards.

Bracket-arm poles, depending upon the length of pipe arm and weight of trolley wire, are made of extra strong pipe, 5 in., 4 in., 3 in., or of standard weight pipe, 6 in., 5 in., 4 in., 27 to 28 feet long, buried from five to six feet in the ground, as soil or setting may require. Bracket-arm poles under side strains should be made of 6 in., 5 in., 4 in., extra strong pipe, and guyed at intervals, as in the case of centre poles under similar conditions.

Poles should align truly, and have, apparently, the same rake. Cast iron bases should be provided to conceal the marring of flagstones or sidewalks which might otherwise be difficult to repair.

Before setting iron poles, the butts, for a distance of at least one foot above the ground line, should be thoroughly painted with a heavy coat of asphalt or other preservative paint. It is assumed that the poles have already received at least one coat of paint to prevent rusting while in transport or on storage. Where circumstances permit, it is highly desirable to paint iron poles with one of the better insulating paints which are manufactured for this and similar purposes. The point of greatest strain is at the ground line. This is also the point at which the paint deteriorates most rapidly, owing to alternate wet and dryness. Frequent painting here will undoubtedly add several years to the life and strength of the pole.

Poles should be painted at least once every three years, and oftener, if required. Handsomely painted poles add much to the appearance of a line.

CENTRAL STATION STATISTICS.

BY

Horatio A. Foster

I notice on page 352 of the April 6th issue of the Engineer Mr. Pope's remarks on the "Status of Lighting Companies in Massachusetts," and think I am in position to appreciate the difficulty of getting just the detail he asks for. I wish to call Mr. Pope's attention to the following list of expenses as asked for in the schedule for Electric Lighting Central Stations by the United States Census Bureau. I think it would be difficult to devise a list which would more accurately cover the points he names.

When it comes to filling it out the trouble begins, as a large proportion of the companies divide their expenses among very few accounts, many having but one account, and that "expense," to which is charged everything from coal to a dynamo brush. Again, many keep no double-entry books whatever. I have examined a large number of central stations in the past year, and think I can appreciate the position of the Massachusetts gas commission when they ask for a law to enable them to fine companies for not returning their schedules.

Expenses as asked for in Census Schedule for Central Lighting Stations.

Office Expense:
  Rent, salaries, sundries.

General Fixed Charges:
  Insurance, total annual premium.
  Interest, at — per cent., on total investment.
  Taxes, rate per cent. —, annual amount.
  Patent licenses and royalties.
  Franchise licenses and royalties.
  Depreciation on buildings.

Steam Plant, Station Expenses:
  Wages.—Engineers, firemen, helpers, etc.
  Supplies.—Fuel, oil, waste water, repairs, sundries.

Fixed Charges:
  Rent, annual amount (divide with electric plant).
  Depreciation on plant, rate per cent. —, annual amount.

Electric Plant, Station Expenses:
  Wages.—Dynamo engineers, helpers, etc.
  Supplies.—Oil, waste, repairs, sundries.

Fixed Charges:
  Rent, total annual amount (divide with steam plant).
  Depreciation on plant, rate per cent. —, annual amount.

Distribution Expenses:
  Wages.—Superintendent, inspectors, linemen, trimmers, all other employees.
  Supplies.—Incandescent lamps for renewals, carbons for arc lamps, globes for arc lamps, hoods for arc lamps, lamp repairs, poles and other supports, repairs, wire used for repairs, sundry supplies, sundry repairs, contingencies.

Fixed charges.—Rentals for poles, rentals for housetop privileges, rentals for elevated railway privileges, rentals for conduits and underground, depreciation on line construction at rate per cent.—, total annual amount.

WATER-POWER PLANT EXPENSE:
Repairs, depreciation, rate per cent.—, total amount; sundry charges for maintenance, rental if not owned.

RECAPITULATION:
Office expense.
General fixed charges.
Steam plant.
Water-power plant.
Electric plant.
Distribution.
TOTAL.

PUTTING IN EDISON HOUSE SERVICES IN BOSTON.

RECENT issues of THE ELECTRICAL ENGINEER have contained descriptions of the methods of putting in Edison house services in New York and Boston, and below we give the details of the work as done in the Boston Edison stations, and for which we are indebted to Mr. C. L. Edgar, general superintendent of the company.

Three forms are employed in order to keep a thorough check on the work.

Cause of trouble..........

The first form, No. 1, is given to the foreman to connect the service at the given place, and states the size of the service and the account to which it is to be charged. This slip is numbered, as will be noted, and is accompanied by a duplicate. The original slip is given to the foreman and the duplicate is entered upon a slip-book in the office. This number follows the job throughout of all stock used and of labor spent upon the same. After the foreman receives this slip he, in turn, issues slip No. 2 to the jointer, who is to put in the service. This is for the use of the jointer in keeping the amount of stock used and time consumed on the job, and at the same time, if he is working on repair work, to make remarks on the trouble found, etc.

After the job is completed the foreman turns back the original slip, Form 1, together with a cost slip, Form 3, which shows the total amount of stock used and the time consumed on the job and the size and length of the service. This is compared with the amount of stock which is charged on the books against that number, and, if it checks, is entered up on the stock statement and charged against the proper account.

DYNAMO-ELECTRIC MACHINERY.—I.[1]

BY J. HOPKINSON, F. R. S., AND E. WILSON.[2]

THE following is intended as completion of a paper by Drs. J. and E. Hopkinson (*Phil Trans.*, 1886, p. 331). The motive is to verify by experiment theoretical results concerning the effect of the currents in the armature of dynamo machines on the amount and distribution of the magnetic field which were given in that paper, but which were left without verification. For the sake of completeness, part of the work is given over again.

The two dynamos experimented upon were constructed by Messrs. Siemens Brothers & Co., and are identical, as far as it is possible to make them. They are mounted upon a common baseplate, their axles being coupled together, and are referred to in this paper respectively as No. 1 and No. 2.

Each dynamo has a single magnetic circuit consisting of two vertical limbs extended at their lower extremities to form the pole-pieces, and having their upper extremities connected by a yoke of rectangular section. Each limb, together with its pole-piece, is formed of a single forging of wrought iron. These forgings, as also that of the yoke, are built up of hammered scrap iron, and afterwards carefully annealed. Gun-metal castings bolted to the base-plate of the machine support the magnets.

The magnetizing coils on each limb consist of 16 layers of copper wire 2 mm. diameter, making a total of 3,968 convolutions for each machine. The pole-pieces are bored out to receive the armature, leaving a gap above and below subtending an angle of 68 degrees at the centre of the shaft. The opposing surfaces of the gap are 1.4 cm. deep.

The following table gives the leading dimensions of the machine:

	cm.
Length of magnet limb	66.04
Width of magnet limb	11.43
Breadth of magnet limb	38.10
Length of yoke	38.10
Width of yoke	12.06
Depth of yoke	11.43
Distance between centres of limbs	23.50
Bore of fields	21.21
Depth of pole-piece	20.32
Thickness of gun-metal base	10.80
Width of gap	12.06

---

[1] Abstract of paper read before the Royal Society.

[2] It must not be supposed from his name not appearing in this short paper that my brother, Dr. E. Hopkinson, had a minor part in the earlier paper. He not only did the most laborious part of the experimental work, but contributed his proper share to whatever there may be of merit in the theoretical part of the paper.—J. H.

The armature core is built up of soft-iron discs, No. 24 B. W. G., which are held between two end plates screwed on the shaft.

The following table gives the leading dimensions of the armature:

	cm.
Diameter of core	18.41
Diameter of shaft	4.76
Length of core	38.10

The core is wound longitudinally according to the von Hefner-Alteneck principle with 208 bars made of copper strip, each 9 mm. deep by 18 mm. thick. The commutator is formed of 52 hard-drawn copper segments insulated with mica, and the connections to the armature so made that the plane of commutation in the commutator is vertical when no current is passing through the armature.

Each dynamo is intended for a normal output of 80 amperes, 140 volts, at 880 revolutions per minute. The resistance of the armature measured between opposite bars of the commutator is 0.042 ohm, and of each magnet coil 13.3 ohms.

In the machine, the armature core has a greater cross-section than the magnet cores, and consequently the magnetizing force used therein may be neglected. The yoke has the same section as the magnet cores, and is therefore included therein, as is also the pole-piece. The formula connecting the line integral of the magnetizing force and the induction takes the short form $4\pi n c = 2l_2\, I/A_2 + l_3 f(\nu I/A_3)$,[3] where

n is the number of turns round magnet.

c is the current round magnet in absolute measure.

l_2 the distance from iron of armature to rim of magnet.

A_2 the corrected area of field.

I the total induction through armature.

l_3 the mean length of lines of magnetic force in magnets.

A_3 the area of section of magnets.

ν the ratio of induction in magnets to induction in armature.

f the function which the magnetizing force is of the induction in the case of the machine actually taken from Dr. J. Hopkinson on the "Magnetization of Iron," *Phil. Trans.*, 1885, Figs. 4 and 5, Plate 47.

In estimating A_2 we take the mean of the diameter of the core and of the bore of the magnets, 19.8 cm., and the angle subtended by the pole-face, 112 degrees, and we add a fringe all round the area of the pole-face equal in width to the distance of the core from the pole-face. This is a wider fringe than was used in the earlier experiments (*Phil. Trans.*, p. 337), because the form of the magnets differs slightly. The area so estimated is 906 sq. cm.

l_3 is taken to be 108.8 cm.

A_3 is 435.5 sq. cm.

ν was determined by the ballistic galvanometer to be 1.47. It is to be expected that, as the core is actually greater in area than the magnets, ν will be more nearly constant than in the earlier experiments. It was found to be constant within the limits of errors of observation.

Referring to Fig. 1, the curve C is the curve $x = l_3 f(\nu\, y/A_3,)$ and the straight line B is the curve $x = 2\, l_2\, y/A_2$, whilst the full line D is the characteristic curve of the machine $x = 2\, l_2 y/A_2 + l_3 f(\nu\, y/A_3,)$ as given by calculation.

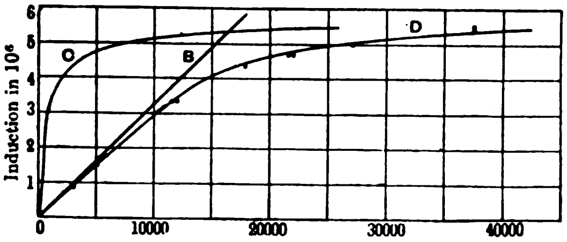

FIG. 1.

The marks + indicate the results of actual observations on machine No. 1, and the marks 0 the results on machine No. 2, the total induction I being given by the equation:

$$I = \frac{\text{Potential difference in volts} \times 10^8}{208 \times \text{revolutions per second}}.$$

Experiments made upon the power taken to drive the machine under different conditions show that it takes about 250 watts more power to turn the armature at 660 revolutions when the magnets are normally excited than when they are not excited at all. The volume of the core is 9,465 cub. cm., or in each complete cycle the loss per cub. cm. is

$$\frac{250 \times 10^7}{11 \times 9{,}465} = 24{,}000 \text{ ergs.}$$

The loss by hysteresis is about 13,000 (*Phil. Trans.*, 1885, p. 463) if the reversals are made by variation of intensity of the magnetizing force, and the iron is good wrought-iron. This result is similar to that in the earlier paper (p. 352), where it is shown that the actual loss in the core, when magnetized, is greater than can be accounted for by the known value of hysteresis.

THE FISHER AUTOMATIC CUT-OUTS.

BY

HENRY W. FISHER.

THESE cut-outs are designed so as to open the main circuit or any other circuit when the E. M. F. of the working circuit becomes greater than that for which the cut-out has been set. The principle on which they operate is believed by the writer to be entirely new and is exemplified in the accompanying engravings, Figs. 1 and 2, which represent a cut-out designed for arc circuits. The former shows the position of the various parts before operation and the latter after operation.

It will be noticed that the essential feature of the cut-out is a fine, strong thread that passes between two sets of needle points, holding by suitable fixtures the arms of the switch in place. As soon as this thread is burned by the passage of a spark across the points, the circuit is instantly opened, as shown in Fig. 2, and as will be more fully explained later on. The writer will first describe the arc light cut-out, then he will mention some rather severe tests to which it was subjected and the various uses which it subserves.

The cut-out, as shown in Fig. 2, is about 20 inches long and 8 inches wide; it can be adjusted so as to open the circuit at any voltage ranging from 1,000 to 6,000 volts; its action is extremely rapid, and it responds instantly to an increase of E. M. F., which may happen to reach or become greater than the voltage for which it is set. The central part is a piece of hard rubber upon which certain brass pieces are mounted; this hard rubber base is removed by taking hold of the handle *j* and pulling in an upward and outward direction. The writer can best describe it by telling how to reset the various parts.

After the circuit has been opened, as shown in Fig. 2, the hard-rubber piece is removed and then one end of the thread is knotted and placed in the groove *f*; then the thread is extended around the pins in *m* and *m'*, back from the point in *e* around *f*, whereupon the string is brought into tension by turning the spool, at the same time loosening or relieving *m* and *m'* until they and *e e* assume the position shown in Fig. 1. The old needles are now removed from the grooves in *k k* and *l*, replacing them by new ones; the needles in *l* are fixed so that the points are just above and touching the thread; the gauge is placed between each set of points in turn and the needles in *k* are advanced until the points are just the thickness of a gauge apart. Mention will be made of this gauge later on.

The parts *h h* are resistances, which are designed so as to stand the strain of being suddenly subjected to high voltages and yet which permit sufficient current to pass to burn the thread instantly. When the hard-rubber part is set up for the first time, or when the cut-out is going to be used for a different voltage, the resistances *h h* are inserted for the voltage in question between the holders *i* and *i'*. The resistances as sent out on the market are stamped for the voltage for which they are to be used, but they will stand under the action of the cut-out two or three times the pressure for which they are designed.

The rubber base is now ready to be put in place, and to do this the brass catch *d* is placed in a groove in the marble and the rubber base is brought into its final position by pressing with a downward and inward pressure; by so doing *p* is connected electrically with *m*, *q* with *o*, *p'* with *m'* and *l* to a ground wire terminal at the back of the marble base. The base is fastened to the wall in a vertical position by four long screws, and is held from the wall by four suitable pillars or insulators; after the hard rubber part is in place, the arms *c c* are latched with *e e*; then the rubber handles *x x* are grasped and the notched connectors *z z* are forced into place. Before closing these, however, it is advisable to regulate the pressure of the brushes *v v* by their screws, so that the collar *t t* will just be forced all the way to *r r* by the springs *s s*.

The main wires from the dynamo are connected to *r r* by suitable binding posts, and the wires running to the outside circuit are taken off from *a a*. The arms *c c* are made of spring brass so as to allow the end of the connectors to be shoved into place in order to hold them and to make good electrical contact. They are made light, and, being under considerable strain, they move very rapidly, thus liberating the connecting rods *w w* instantly. The springs *s s* are very strong, and, by the method by which they are made to move the arms *w w*, great rapidity of break is insured; moreover, the springs *g g* are designed so as to impart rapid motion to the parts *e e*; these also serve as a means of making electrical connection from *e* to *i*; it will be noticed that the instant the cut-out operates, the electrical connection is broken between the lugs *a a* and *e e* by means of the arms *c c*; this prevents the resistances *h h* from being injured in case there happens to be a cross on the outside circuit such as might otherwise cause a current of electricity to flow from *a* to *a* through these resistances. In this particular cut-out both sides of the circuit are broken through a distance of ten inches. The marble slabs 2 2 extend over an inch above the highest of the other parts and thus effectually prevent the rubber or any of its parts from being injured by any arc that might occur at *b b*.

---

[3] *Phil. Trans.* p. 335.

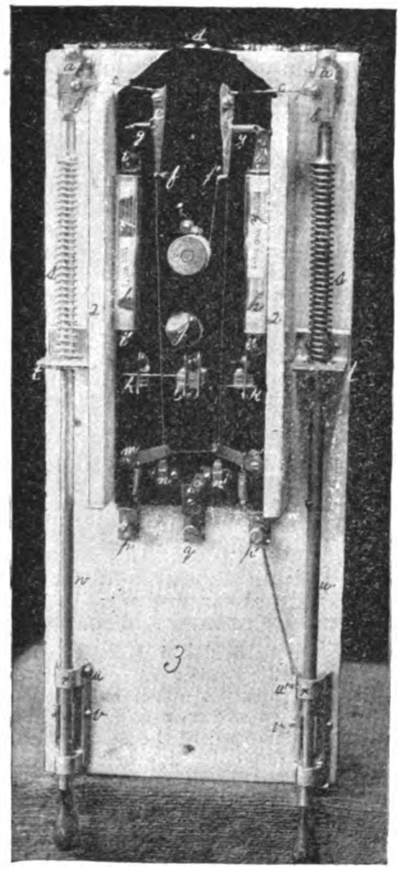

FIG. 1.—FISHER AUTOMATIC CUT-OUT.

The writer will now explain the function of the lower parts of the hard-rubber strip and the corresponding parts *p*, *q* and *p'* in the marble. A third wire is run from the brush of the field side of the dynamo to *q*. The connector *o* is constructed so that electrical connection can be made between *q* and *n'* or between *q* and *n*, as desired; *p* or *p'* can also be connected to *u* or *u'* by a suitable wire. The object of the switches *m* or *m'* is to short-circuit the field coils of the dynamo at the instant the thread burns and this is effected by connecting the field side of the circuit with *p* or *p'*, as the case may be, placing the connector *o* at the corresponding side of the circuit. This is shown in Fig. 1, where *p'* is connected with *u'*, *u'* being a part of the brush side of the circuit; practically, the main circuit is opened simultaneously with the closing of the switches *m* and *m'*; but from several tests made the switch *m'* acts rapidly enough to cause a sudden drop of E. M. F. of the dynamo so that there is no apparent arc of breaking, and the sudden resultant rise of E. M. F., so destructive to the insulation of cable circuits, is avoided.

The object of having duplicate parts *p*, *p*, *m*, *m*, as shown in the figures, is to facilitate the linemen in making the necessary connections in case the cut-out is to be placed in a station where the wiring has already been done. If desired, an annunciator can be operated by the closing of the switch *m* or *m'*, which is not used for cutting out the field coils, thus notifying the engineer in charge that the circuit has been opened. In connection with this cut-out a suitable apparatus for measuring the double-spark length has been designed; this apparatus, by means of a micrometer device, enables one to determine the length of the air gaps for the normal E. M. F. of any given machine; having determined this to one one-thousandth of an inch, a suitable gauge of copper is constructed; this gauge, however, must be made slightly thicker than the actual sparking distance for the voltage in question. The increase in the thickness of the gauge above the actual sparking distance, depends upon the voltage and upon the type of machine. The object of doing this, of course, is to have the needle points set at such a distance that the normal working of the dynamo will not be interfered with by the opening of the circuit by the cut-out. In stations where it may be difficult to reset the parts on the hard-rubber instantly, it is desirable to use a duplicate part which can be instantly put into place, the other being reset at the leisure of the engineer in charge.

A number of tests were made with this cut-out in order to test its thorough reliability under all conditions, the alternating current being used for convenience.

Test No. 1. The needle points were adjusted so that the cut-out would not operate under a pressure of 1,000 volts, but would do so the instant the voltage was increased to 1,500 volts. The wires were run from the part *a a* of the cut-out to ten 100-volt lamps in series, which, of course, were just brought up to candle power by the 1,000-volt circuit; instantly the voltage was increased to 1,500 volts, whereupon the cut-out opened the circuit so rapidly that the lamps had not time to become any brighter.

Test No. 2. The needle points were set as before, the same ten lamps were placed in series, but a pressure of 2,000 volts was used; and upon closing the circuit switch the cut-out operated so rapidly that the filaments of the incandescent lamps had not time to reach their normal candle power, whereas, if this voltage had been placed on the lamp circuit for even a very short length of time one or more of the lamps would certainly have burned out.

The writer neglected to mention before the function of the part 1; it was stated that when the rubber piece is put in place, 1 is connected to a ground wire terminal at the back of the marble base; the object of this is twofold. In the first place, it enables the cut-out to be usd as a lightning arrester for the lightning discharge will choose the point of least resistance, namely, through the small air gaps at the needle points to ground, and this it can do from either side of the circuit, thus opening both sides of the circuit and saving the dynamo from being burned out by the lightning discharge. The second function of the ground wire connected to 1 is to enable the cut-out to open the circuit whenever a ground appears, or even when the insulation of a circuit becomes dangerously low; this is evident when we consider that by grounding one side of a circuit the air-gap has been reduced to one-half, and hence, unless there are more grounds than one in the circuit, and unless the insulation is proportionately low all over the circuit, there will be a spark across the points and the circuit will be opened.

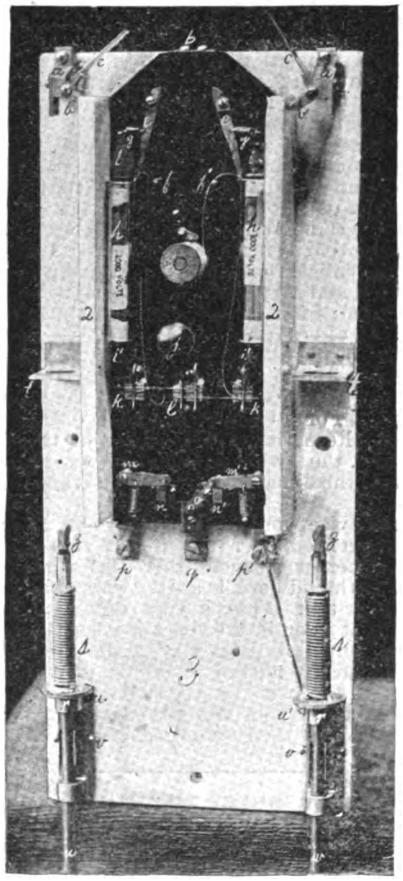

FIG. 2.—FISHER AUTOMATIC CUT-OUT.

Test No. 3. This was made to illustrate the working of the cut-out when one side of the circuit became grounded. The needle points were set so that 1,000 volts would not operate the cut-out; a pressure of 1,000 volts was used. One side of the circuit was grounded, whereupon the circuit was opened instantly.

Test No. 4. This was the most exacting test to which the cut-out was subjected and it forcibly illustrates the exceeding rapidity with which the device operates. Pieces of a cable having very thin insulation were tested with a view to determining what voltage would break through this insulation; 2,000 volts were found to do this, and so far as could be determined by the senses, the cable broke down the instant the 2,000-volt switch was closed; then a piece of this cable was connected to the circuit side of the cut-out, the points were adjusted so that the cut-out would operate under 2,000 volts and then a pressure of 2,000 volts was connected to the other terminals of the cut-out; upon closing the circuit switch the cut-out opened the circuit so rapidly that the cable was not in any way injured, as was shown by a subsequent insulation test. The same pressure was then connected directly to this same piece of cable, whereupon it broke down instantly. Subsequent tests demonstrated the efficiency of the cut-out as a protective device against burn-outs which might be caused in absence of the cut-out by the abnormal rising of the E. M. F.

The cut-out was also tested at the arc station of the Allegheny County Light Company, and a practical test was witnessed by the officials of that company, who expressed themselves as being well pleased with the result. The needle points were first set so that the cut-out would operate before the E. M. F. of the arc machine reached its normal value, namely, 2,800 volts. The cut-out operated so easily that no one present became aware of the fact for several seconds after its operation; then the points were set so that the cut-out would not operate under the normal working of the machine; after the lamps were up to full candle power one side of the circuit was grounded, the result being that the cut-out opened the circuit and the action of the short-circuit switch was so rapid that there was no visible arc whatever at the time of breaking, whereas, usually the arc is several inches long. This shows that this form of cut-out can be used on high voltage arc circuits operating through a system of underground cables, and that there need be no fear of the cables being injured by the sudden opening of a circuit by means of the cut-out.

Briefly summing up the uses of the cut-out, it may be considered as being a protection to dynamos and cables against abnormal rises in the E. M. F. of a dynamo, against crosses that may tend to augment the E. M. F. of a dynamo, against lightning discharges and against grounds. If the circuit becomes grounded and it is still necessary to operate the machine, the remedy is to disconnect the ground wire from the marble base; but this is, of course, only recommended as a temporary alternative.

The other styles of cut-outs embody the principles of the one just described, the same style of connectors and the vertical accelerated drop motion being used. The parts as shown in the lower part of the rubber base in the accompanying figures, are, however, different and they are made to suit the style of machine under consideration; for instance, if the cut-out is designed to be operated upon an alternating circuit and if it was desirable to lower the E. M. F. of the alternator before, or at the same time the circuit was opened by the cut-out, the parts *m* and *m'* would be designed so as to open the exciter circuit of the alternator at the instant of break. For a dynamo machine operating under the principle of the alternating arc machine of the Westinghouse Electric Company, the switches *m* and *m'* would be designed so as to short-circuit the dynamo slightly in advance of opening up the main circuit.

This form of device would seem to have an advantage, so far as rapidity is concerned, over the cut-outs that use the principle of the electromagnet or solenoid, there being no retardation in the circuit. The thread used is a silk twist which is very strong and yet so slender that it burns very quickly. It is stretched very tightly so that even if the spark is a small one, long before the thread is consumed it gives way under the tension and this sudden releasing has a tendency to augment the movement of the parts that are held in place by the string. This device was designed in the laboratory of the Standard Underground Cable Company, and made in their own machine shop.

THE MAGNETIC CLUB DINNER TO THE HON. JAMES D. REID.

A MOST successful dinner was given on Saturday, April 30, at the Columbia, West Fourteenth street, by the Magnetic Club to the Hon. James D. Reid, U. S. Consul at Dunfermline, Scotland, who is now on a visit to this country to celebrate his golden wedding. More than 150 members and friends sat down to dinner, under the chairmanship of Mr. W. H. Baker, in the unfortunate absence of President Cockey, who was detained at home by illness. After dinner, Mr. Baker gracefully called on Mr. W. J. Dealy to preside, and then began a flow of oratory, song and mirth that lasted pretty well all through the "red message" hours. Mr. Dealy was himself never more eloquent. Mr. Reid was received with many rounds of applause and repaid them in some very tender and charming words of thanks, the pathos and humor of which showed that he had not been spending his time in the land of Robbie Burns for nothing. The most interesting part of his address was that in which he referred to recent efforts to belittle the fame and memory of Prof. Morse, and called upon his hearers to do all in their power, should occasion arise, to defend the pure reputation of the man who had founded the great telegraphic industry with which they were all connected. Mr. Reid's eloquent appeal in behalf of his old chief and friend was heard with the closest attention and was greeted with warm approval. The other speakers were Messrs. T. F. Clark, C. A. Tinker, W. C. Humstone and R. J. Hutchinson.

BOSTON SOCIETY OF OPERATIVE ELECTRICIANS.

THE BOSTON SOCIETY OF OPERATIVE ELECTRICIANS held its regular semi-monthly meeting at the American House, last Wednesday evening, President A. T. Chase, presiding. The speaker of the evening was Mr. A. T. MacCoy, electrician of the United Telegram Co., who presented an elaborate and carefully prepared paper on the system of that company for the distribution of stock quotations. The various instruments used and the arrangement of apparatus and circuits were carefully explained, being illustrated by some of the actual apparatus and by numerous diagrams. Mr. MacCoy's paper presented in a striking manner the completeness with which the details of this system have been elaborated, and formed a worthy addition to the numerous interesting and instructive papers with which the society has been favored during the past season.

The society aims especially to bring before its members by lectures and discussions the practical applications of electrical science to regular commercial work; and persons interested in the work of the society or who might desire to become members are welcome to attend any of the meetings, which are held the first and third Wednesdays of each month at 8 P. M., at the American House, Boston.

TROPICAL AMERICAN TELEPHONE CO. DISSOLUTION.

UPON the application of Charles M. Hough, complainant, Hon. Alex. T. McGill, chancellor, issued an order, at Newark, N. J., April 20, directing the Tropical American Telephone Co. to show cause why an injuction should not issue and a receiver be appointed to close up its business; at the same time ordering that corporation to refrain from collecting or paying any money and from selling or transferring any of its property. The valid assets of the company are understood to be insufficient to meet its liabilities. It is not true as reported in other journals that the Western Electric Company has purchased a majority or any of the stock of the Tropical American Telephone Co.

AN IMPORTANT LIGHT AND POWER ENTERPRISE AT CONCORD, N. H.

THE CONCORD LAND AND WATER CO., of Concord, N. H., Geo. F. Page, president, is beginning to carry out a very important light and power enterprise.

The facts, briefly stated, are that a dam is to be constructed at Sewall's Falls during the coming season, work to be commenced upon it in May; the dam to be completed by the middle of November; the increased capital for the work being already pledged. A canvass of the city of Concord has been made for lighting and is being made for power. More than 124 arc and more than 5,000 incandescent lights, besides isolated plants, are already assured in the city of Concord. New industries are being invited, and it is expected that some will be constructed and begin manufacturing at an early day on the ground at Sewall's Falls, which is four miles above the State House or central wards of the city. Sewall's Falls are in the Merrimack River. There is a head and fall of 22 feet. A reservoir will extend 13 miles up stream when the dam is built and the flash boards are in place; 5,000 h. p. can be secured the year round by the electric installation which it is proposed to make, for it is intended to develop all the power through dynamos and distribute this power on the ground and elsewhere electrically. A beautiful site for the erection of buildings, both for residences and manufacturing purposes, is afforded by the land contiguous to the Falls. Two railways in competition pass through the property, and an electric railway passes along at one side thereof. The company will offer to parties who desire cheap land and cheap power excellent facilities for manufacturing. The rates of transportation are low. Exemption from taxation for a term of years can be secured, and everything is offered that can be asked for to make this a thriving settlement. The proposed town site will form a ward of the city of Concord, which is the capital of the State. The very best of electrical apparatus will be employed. The company are under no obligations to any one company, as they will pay cash for what they purchase, and all the work will be done under the most thorough system of engineering possible. It is intended to make this a model electrical plant in every particular, and finer than any other in the country at the present time.

Legal Notes.

THE EDISON INCANDESCENT LAMP PATENT—FINAL HEARING BEFORE THE U. S. CIRCUIT COURT OF APPEALS.

THE suit of the Edison Electric Light Company against the United States Lighting Company, for an alleged infringement of Edison's patent for an incandescent lamp, No. 223,898, which has been pending in the United States courts since May, 1885, came up on appeal for final hearing and determination on April 25, before Justices Lacombe and Shipman, in the United States Circuit Court of Appeals for the second circuit. The present hearing is an appeal from the decree of Judge Wallace, in the Circuit Court, filed July 14, 1891, by which the Edison patent was sustained and the defendant's lamps held to be infringements. An imposing array of eminent counsel were present. The Edison Company were represented by S. B. Eaton, G. P. Lowrey, C. A. Seward, A. H. Walker and R. N. Dyer. The United States Company were represented by S. A. Duncan, L. E. Curtis, E. Wetmore, and F. H. Betts.

Mr. Wetmore, in behalf of the United States Co., after rehearsing the history of the litigation in the lower court, proceeded to a consideration of one of the defenses in the case. Before proceeding to discuss the patent itself, and the issues of novelty and infringement, he would speak of a defense which was established by an admission of fact. It was that there was no complainant in this case. The corporate existence of the plaintiff, "The Edison Electric Light Company," had ceased on December 31, 1886, when that company had been consolidated with the "Edison Company for Isolated Lighting" to form a new company known as "Edison Electric Light Company." Notwithstanding the provisions of the State law, he contended that the act of consolidation conveyed no legal title in the patent in suit to the new company. Such title could only pass by a written assignment as required by the Federal statute, consequently the new company was incompetent to prosecute suit for an injunction, either in its own name or under the name of the old company, nor could the original plaintiff company longer ask for an injuuction. Its corporate functions had expired with the consolidation, it had ceased to manufacture under the patent or to exercise control over it and could no longer be injured by any infringement. The only regular procedure would have been to have transferred the legal title of the patent to the consolidated company, and then for that company under proper proceedings to have secured substitution. This not having been done, there was no party before the court entitled to an injunction. The State law provided that suits pending at the time of consolidation might be continued in the name of the old company, by order of the court in which the proceedings were pending, but a patent monopoly was surely a question of statute, and could in no wise be affected by any State legislation. The suit must be brought by the owner of the legal title. This had been established by a long series of Federal decisions. It was a matter wholly beyond the jurisdiction of the State Legislature.

General Duncan, in opening the main portion of the case for the United States Company, contended that the granting of an injunction was a substantial error of the court below. Even upon its interpretation of the patent, it ought not, in view of the equities of the case, have enjoined the defendant—certainly not upon an interlocutory decree, provided it was willing to enter into bonds to pay the plaintiff a reasonable compensation for the continued use of the invention, in case the patent had been ultimately sustained with the broad construction adopted by the circuit court. The defendant had entered upon the business of incandescent lighting, involving the use of the alleged infringing lamp early in 1880, a date practically contemporaneous with the issue of the patent in suit. It had prosecuted the business diligently and at the date of the commencement of the suit it had installed over 1,000 lighting plants having a capacity of 350,000 lamps representing a cash investment on the part of the purchasers of $5,000,000, and had itself invested capital approximating $2,000,000. The infringement complained of had beeen carried on openly in all parts of the country for five years before the commencement of the suit. Important contracts had been obtained by defendant in competition with the plaintiff. Finding abundant reason in plaintiff's conduct to suppose that no attack would be made, defendant had gradually enlarged its operations from year to year, and had been led to invest a vast amount of money in the business of manufacturing, all of which capital would be imperiled if an injunction were to be granted. Moreover, the plaintiff by its contracts with Mr. Edison, had parted with its right to manufacture lamps and by its contract with local companies had parted with the right in the large part of the territory of the country to use and sell lamps embodying the Edison invention. It did not appear that the plaintiff, who was not a manufacturer of lamps, would suffer more than a merely nominal injury for the refusal of the injunction, while the granting of the injunction would imperil millions of capital, not merely capital invested by the defendant, but the capital of local lighting companies in all parts of the country. Under all the circumstances, sound practice would seem to have dictated, that the question of injunction should have been reserved until the coming in of the master's report, and the settlement of the final decree. Either therefore the decree below should be reversed absolutely as to the injunction clause, or the injunction should be modified, and made conditional upon defendant's refusal to file the bond with proper security to pay plaintiff such royalty for the lamps which it might hereafter make, use or sell, as the court should ultimately adjudge be reasonable and just.

Two excuses had been offered for the delay in commencing this suit. Major Eaton, who was then president of the company, has testified that they were perfectly aware of the competition of the defendant, but did not think it amounted to much and did not care to spend time or money in prosecuting the matter. They proposed to wait until the business of the defendant had become of serious importance. They say furthermore that they preserved their legal rights by giving notice to the defendant, which was all they were required to do. Defendant would contend that the reasons which had been assigned for that delay were not substantiated by the record. The infringement had been of a serious character. Two years after the date of the patent the Edison Company had sold 34,000 lamps; three months after that the defendant had sold 36,000 lamps. The notices alleged to have been sent out contained simply a list of 160 patents, and a statement to the world at large that if any one of those patents should be infringed, the company was going for them. Defendant had received a copy of the notice and so had all other electric lighting companies. Such a notice could not establish a right to wait indefinitely before suing for an infringement that had been going on on a large scale for years. Their other excuse had been that the state of the law by repeated decisions in the Circuit Court had led them to believe that the patent now in suit had expired by reason of a prior short-term Canadian patent; that they had a right to rely upon that as the settled law, and that it so continued until the Supreme Court in January, 1889, had reversed the decision of the circuit, and hence that from that time only they had been chargeable with diligence in the prosecution of infringers. But they could not complain if defendants also, relying not only on plaintiff's delay in bringing suit, but upon repeated adjudications in circuit, had invested millions of dollars in the business of building up electric light manufactures; and having done that during the pendency of plaintiff's delay, it did not lie in their mouths now to say that they had a right under the law, as it had been expounded though erroneously by the lower court, to delay bringing suit during all that time.

Upon the admitted facts as presented, what was the part of equity? If it were true that during this period of delay, defendant had maintained active competition with plaintiff, and had received no notice from plaintiff alleging infringement upon the rights covered by this patent, were they to be enjoined? If for every lamp sold there had been put out apparatus twenty times the value of the lamp, was an injunction to go that would destroy those investments? Was there any corresponding benefit to the plaintiff which would justify such a harsh application of the doctrine of injunction? He would contend also, that in view of the extraordinary laches in this case, it was incumbent upon the plaintiff to show affirmatively that no injury would come to the public. What was going to become of the $80 invested in electric plants for every dollar invested in lamps? General Duncan then cited a great number of cases in which the court had refused an injunction, on the ground that the owners of the patent had been dilatory in asserting their rights, and contended that even if it were true that there had been no adjudicated cases in which laches had continued for a period less than five years, and in which the court had refused an injunction, that was no reason why this court should not make a precedent. The question was, What was equity? Judge Story, in *Wyeth vs. Stone*, after citing a long list of authorities, had thrown them all aside and had said: "But if there were no authority on this point, I should not have the slightest difficulty in asserting the doctrine, as founded in the very nature and character of the jurisdiction exercised by courts of equity on this and other analogous subjects." To say that the plaintiff had not lost his rights because he had not waited six years, when, in fact, he waited five years, and until defendant had invested millions of dollars, believing that he had a right to make this right seemed almost puerile.

General Duncan then entered upon elaborate explanation of the construction and the principles involved in the operation of the incandescent lamp, which lack of space reluctantly compels us to omit. In the course of this, he pointed out the importance of high resistance in the lamp, and called attention to three elements of resistance which he said were important to be kept in mind, viz., specific resistance, cross-section and length, all of which were determining factors in the total resistance. In electric lighting by incandescence there was one prime rule to be observed, which was not only embodied in all modern commercial lamps, but from defendant's point of view had been embodied in every lamp ever made. It referred to the smallness of the cross-section of the burner. If it were asked what is meant by "smallness of cross-section," it was difficult to answer. The other side had contended that it was the very essence of the invention covered by the patent, but neither in all the discussion in the court below nor in the voluminous brief filed in the present case had defendants answered that question. General Duncan then explained that it was desirable, in order to keep down the volume of light, to have a small burner rather than a large one. Another reason for having a small cross-section was to get the necessary resistance for economical work. A third reason was that with the limited supply of current a small burner might be brought to incandescence when it would be impossible to do so with a large one. The remainder of the day was occupied by General Duncan in explaining the difference in the results obtained by arranging the lamps in series or in multiple arc.

TAXING THE WESTINGHOUSE CO. NOT LEGAL.

In the case of the Westinghouse Electric Company the Supreme Court of Pennsylvania has held that it is a manufacturing corporation, and therefore not liable to tax on its capital stock, which is largely invested in patent rights covering important improvements in electrical appliances. The court is careful to point out that while the intangible right existing in a patent may not be taxed, the tangible articles manufactured under patent rights are legitimate subjects of taxation.

Society and Club Notes.

PRELIMINARY ARRANGEMENTS FOR THE WORLD'S ELECTRICAL CONGRESS.

Dr. Elisha Gray, chairman of the Committee on Electrical Congress, of the World's Columbian Exposition, has sailed for Europe, where he will spend three or four months devoted chiefly to a study of questions connected with the Congress. Prof. H. S. Carhart, of Ann Arbor, secretary of the committee, will also spend some time abroad. Active work in this country will be resumed in the fall. Before leaving New York for London, Dr. Gray called a meeting of the Eastern members of his advisory council, on April 26, at the headquarters of the American Institute of Electrical Engineers, when a large number participated in an active discussion of various details connected with the organization of the Congress, its work, time of holding it, qualifications of membership, etc. One point that was practically settled is that, if possible, the Congress shall be held the last week in August of 1893.

The following gentlemen have been appointed to constitute the Advisory Council of the World's Congress of Electricians:

England.—Sir William Thomson, F. R. S. (Lord Kelvin), The University, Glasgow; William H. Preece, F. R. S., Electrician-in-Chief, General Post-Office, London; Prof. W. E. Ayrton, F. R. S., City and Guilds of London Institute, Central Institution, Exhibition Road, London; Lord Rayleigh, Terling Place, Witham, Essex; Prof. S. P. Thompson, D. Sc., London.

France.—Prof. E. Mascart, College de France, No. 176 Rue de l'Université, Paris; E. Hospitalier, No. 6 Rue de Clichy, Paris.

Germany.—Dr. Werner Siemens, Berlin; Prof. H. Von Helmholtz, Berlin.

Italy.—Prof. Gallileo Ferraris, Turin.

Austria.—Joseph Kareis, K. K. Baurath, Wien II., am Tabor 6.

Switzerland.—Prof. Dr. Weber, Ecole Polytechnique, Zurich.

Belgium.—Prof. E. Gerard, Inst. Electro-Tech. de Montefiore, Liege.

Russia.—Prof. A. Repman, Moscow; Prof. A. Stoletow, Moscow.

Mexico.—S. Yslas, de los Telegrafos Federales, City of Mexico.

Spain.—Director General of Telegraphs, Madrid.

U. S. A.—Prof. Geo. F. Barker, M. D., University of Pennsylvania, Phila., Pa.; Prof. C. F. Brackett, College of New Jersey, Princeton, N. J.; Prof. Henry A. Rowland, Ph. D., Johns Hopkins University, Baltimore, Md.; Prof. T. C. Mendenhall, LL. D., Director U. S. Coast and Geodetic Survey, Washington, D. C.; Prof. B. F. Thomas, Ohio University, Columbus, Ohio; Prof. Thomas Gray, Rose Polytechnic Institute, Terre Haute, Indiana; Prof. A. E. Dolbear, Tufft's College, College Hill, Mass.; Prof. John Trowbridge, D. Sc., Harvard University, Cambridge, Mass.; Prof. F. E. Nipher, Washington University, St. Louis, Mo.; Prof. Sidney H. Short, Cleveland, Ohio; Prof. Henry Morton, Stevens Institute, Hoboken, N. J.; Prof. Brown Ayres, Tulane University, New Orleans, La.; Prof. John E. Davis, LL. D., University of Wisconsin, Madison, Wis.; Prof. A. P. Carman, Purdue University, Lafayette, Ind.; Prof. Lucian I. Blake, Ph. D., University of Kansas, Lawrence, Kan.; Charles F. Brush, Cleveland, Ohio; Dr. Channing, Pasadena, Cal.; Michael I. Pupin, Ph. D., Columbia College, New York, N. Y.; Prof. Elihu Thomson, Lynn, Mass.; Franklin L. Pope, Elizabeth, N. J.; George M. Phelps, New York, N. Y.; Frank J. Sprague, New York, N. Y.; Edward Weston, Newark, N. J.; Prof. William A. Anthony, Manchester, Conn.; Louis Duncan, Ph. D., Johns Hopkins University, Baltimore, Md.; Prof. Alex. Graham Bell, Washington, D. C.; Francis B. Crocker, Columbia College, New York, N. Y.; Nikola Tesla, New York, N. Y.; Thomas A. Edison, Ph. D., Orange, N. J.; Carl Hering, Philadelphia Pa.; T. Commerford Martin, New York, N. Y.; Prof. Edward L. Nichols, Ph. D., Cornell University, Ithaca, N. Y.; Prof. Edwin J. Houston, Central High School, Philadelphia, Pa.; Dr. William E. Geyer, Stevens Institute of Technology, Hoboken, N. J.; A. E. Kennelly, Orange, N. J.; Thomas D. Lockwood, Boston, Mass.; Louis Bell, Ph. D., Chicago; Prof. Charles R. Cross, Mass. Institute of Technology, Boston, Mass.; George A. Hamilton, Elizabeth, N. J.; Ralph W. Pope, Elizabeth, N. J.

THE CHICAGO ELECTRIC CLUB.

The annual meeting of the Chicago Electric Club was held on April 21st. The following-named gentlemen were selected for the ensuing year:

President, B. E. Sunny; first vice-president, F. B. Badt; second vice-president, Alex. Kempt; third vice-president, M. A. Knapp; fourth vice-president, W. B. Pearson; secretary, W. A. Kreidler; treasurer, F. S. Terry; managers, F. W. Parker, chairman; Geo. C. Bailey, E. Baggot, J. P. Barrett, W. J. Buckley, F. W. Cushing; F. E. Degenhardt, E. R. Gilman, J. J. Nate, C. H. Wilmerding; membership committee, C. C. Haskins, chairman; T. G. Grier, Geo. Cutter.

The old quarters on Adams street, which have been occupied during the last two years, will be deserted on May 1st, when the club will take possession of its new rooms on the northeast corner of Clark and Monroe streets.

CHICAGO ELECTRICAL ASSOCIATION.

The meeting of the Chicago Electrical Association, last week, was cut rather short by the sudden departure of the audience. Mr. F. R. McBerty was reading a paper on the sparking of dynamos and the members were getting warmed up by his treatment of this fiery subject, when it was found that the upper two stories of the building were not only sparking but blazing, and the meeting adjourned *sine die.*

The electrical brethren all got out unscathed. A group of them was afterwards seen watching the work of the "boys in blue," and discussing the uses of electricity for operating extinguishers, and proposing measures to prevent the sparking of buildings.

MEETING OF LA SOCIÉTÉ INTERNATIONALE DES ELECTRICIENS.

At the meeting which took place on the 2d of March, 1892, the president, M. Joubert, reminded the members that the elections for the committee had taken place during the previous month, and that M. Carpentier had been elected president for next year.

M. C. Rechniewski then made a communication on the dissipation of heat in the armatures of dynamo-electric machines. The author has made on this subject a series of experiments. In one machine, having an output of 3,300 watts, in order not to exceed a maximum of 50° C., copper of 440 cubic centimetres, and iron of 1,100 cubic centimetres, was necessary. The total cooling surface was 950 square centimetres. For a machine with a ring armature, to obtain the same conditions, it was necessary to have a cooling surface of 5.73 square centimetres per watt. With a multipolar machine, having a total cooling surface of 7,440 square centimetres, giving 33 amperes at 120 volts, and running at 490 revolutions per minute, M. Rechniewski has found that it is necessary to have a cooling surface of 3.8 square centimetres per watt.

Letters to the Editor.

A PROPHECY OF INDUCTION RAILWAYS.

Referring to your April 20, article on page 411, in connection with an induction electric railway system, I wish to call the attention of your readers to the last paragraph but one of a lecture which I delivered before the Franklin Institute in Feb. 1891, wherein I prophesy an induction system of this kind in the following words: "On the asphalt highways, underlaid in certain lines, separate from the horse-tracks, with induction plates, glide tricycles and other low carriages of analogous light and elegant construction—their motors running at will, when brought over the sunken wire-bound plates."

What I had in mind at the time was of course but a modification of the transformer principle, the primary coils thereof being laid in the ground, as close as possible to the surface, and the secondary coil being carried upon the car. I am not even sure that this suggestion was original with me at the time, as I might have seen a hint of it published somewhere, but cannot be certain upon this point. I do not know what claims are made in regard to the present system in question, but it seems very certain that the inherent principle involved is not entirely new.

OBERLIN SMITH.

BRIDGETON, N. J., April 28, 1892.

Obituary.

EUGENE H. COWLES.

EUGENE H. COWLES, eldest son of the late Edwin Cowles, who was the editor of the Cleveland *Leader*, died on April 21, at El Paso, Texas, where he had gone for his health. Hemorrhage of the lungs caused his death. Mr. Cowles was 38 years old. He was a director and secretary of the Leader Printing Company, and manager of the Cowles Electric Smelting and Aluminum Company, of Lockport, N. Y. Together with his brother, A. H. Cowles, he invented the Cowles process of making aluminum by means of electrical heat, the discovery marking a distinct step in metallurgic progress. He also invented improvements in the overhead trolley system of propelling street cars by electricity.

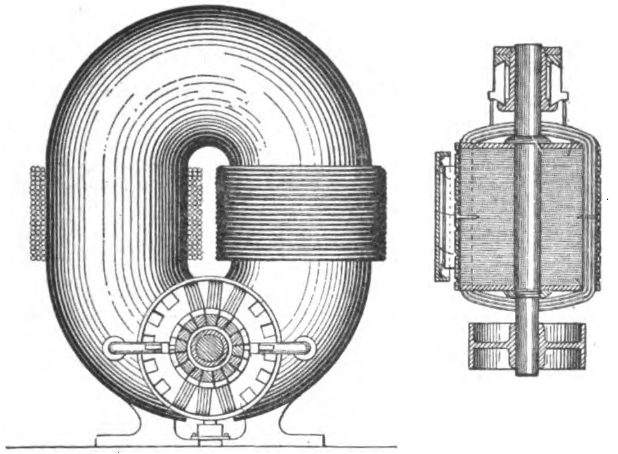
Personal.

DR. F. A. C. PERRINE, who has for some time past been connected with the electrical wire interests of the Roeblings at Trenton, N. J., is resigning there and will go to Boston, where he will join the forces of the Germania Electric Company.

Patent Notes.

A "SHORT" DYNAMO DISPENSING WITH AIR SPACE AND JOURNALS.

IN order to diminish the magnetic resistance of the interpolar space, and also to increase the relative number of the lines of force passing through the armature, Mr. Sidney H. Short, of Cleveland, Ohio, has invented the form of generator shown in the accompanying ilustrations, where Fig. 1 is a side elevation of the machine, partly in section, and Fig. 2 a longitudinal section of the armature and lubricating cup. As will be seen, the armature, covered with a continuous ring of iron, revolves between the pole-pieces which act as a journal, means for lubrication being provided. The field magnets can thus be reduced in size and excited with a less number of ampere turns, while exercising an equal effect in the machine, and are so placed that their action is opposed to that of gravity, which minimizes the pressure on the bearing surfaces.



FIGS. 1 AND 2.—NEW "SHORT" DYNAMO.

This is a most radical departure from existing methods of dynamo construction, and the test of its practical utility will be awaited with interest.

MR. H. F. PARSHALL has been transferred from the electrical engineering department of the Edison General Electric Co. to the Thomson-Houston Works at Lynn, as designer of apparatus and electrical engineer in the railway and power department.

EXTENSIVE ELECTRIC RAILWAY WORK NEAR NEW YORK CITY.

FIVE electric railway companies have just been incorporated in this State to operate in the "annexed district" of New York City. The directors of these companies are Howard Carroll, Thurlow Weed Barnes, George C. Clausen, James McNaughton, Frank M. Pitton, George H. Laurence, Frank T. Scott, William H. Jasper and Charles E. Coddington. A majority of the stock in each company is taken by Carroll and Coddington.

The first of the five is the William's Bridge and Westchester Traction Railroad Company, with a capital of $80,000 and a length of four miles. The termini of this road are to be at the junction of the Bronx River and Olive avenue in the village of William's Bridge and the junction of Main street in the village of Westchester and Westchester Creek.

The second is the Suburban Traction Company, with a capital of $150,000 and a length of five miles. The termini of the main line are the junction of Bronx River and the southern turnpike of Harlem road and the junction of Main street in the village of Westchester and Westchester Creek.

The third is the Hopefield and Westchester Traction Company, with a capital of $100,000 and a length of seven miles. The termini are the intersection of Fifteenth avenue and Third street in the village of William's Bridge and the junction of Long Island Sound with the new road between the Eastern Boulevard and Long Island Sound.

The fourth is called the West Farms and Westchester Traction Company, with a capital of $80,000 and a length of three miles. Its termini are the junction of the Bronx River and the new West Farms Road and the junction of Main street in the village of Westchester and Westchester Creek.

The fifth is called the Van Nest, West Farms and Westchester Traction Company, with a capital of $150,000 and a length of five miles. The termini of its main line are the junction of the Bronx River and the new West Farms Road and the junction of the main street in the village of Westchester and Westchester Creek.

LANDING THE FRENCH CABLE.

THE joint resolution granting to the French Cable Telegraph Company, of Paris and New York, the right to land a cable on the shores of Virginia and South Carolina, thence to go from Cuba to San Domingo, was the subject of a hearing last week before the Senate Committee on Commerce, at which Secretary Blaine, members of the French Legation in Washington, and attorneys for the company were heard. Secretary Blaine made a vigorous protest against the passage of tho resolution, urging that it should be killed in committee. It would, he said, prevent the growth of an American cable system to Brazil.

PLANTÉ AND MODERN ACCUMULATORS.[1]

IT is strange that so much of Planté's work has been ignored and then rediscovered. It is often thought that charging at 2½ volts or more is a modern practice. Planté states that 1½ times the E. M. F. of a Bunsen is all that is necessary. That is to say, he always employs a high enough pressure to charge quickly. He mentions the liberation of gas, and explains when it shows that a cell is charged to saturation and when it does not. Planté did not regard his cells as being solely for filling slowly and emptying quickly; he pointed out that they might be used for charging quickly and discharging slowly. He was also aware of the high initial pressure of a cell after charging and its sudden drop. What is still more remarkable is that Planté pointed out that to keep a cell right it must be charged fully and kept charged. He recommends Bunsens for charging and Daniells for keeping fully charged. He also points out how a fully charged cell protects its own plates from local action. Most of these properties of batteries had to be rediscovered, Messrs. Drake and Gorham and others finding them out gradually. Planté's book went out of print in 1881, and the English translation did not appear till 1887, so that though every electrician knew of Planté, few knew what he had actually done.

The remarkable constancy of pressure or discharge of a Planté cell is almost unknown in modern practice. It is, however, nearly reproduced in the Epstein cell, which will give practically its whole discharge with an exceedingly small fall of pressure.

THE ELECTRIC PLANT ON LEAK'S ADVERTISING CAR.

THE ROCKFORD MFG. CO., of Rockford, Ill., furnished some time ago a small lighting plant, comprising a boiler, six h. p. engine and 60-light dynamo for Leak's private car, which is now in Chicago, and parties interested in the products of Place county, Cal., are invited to inspect the same. The plant runs 65-lights and has done excellent work and Mr. M. Leak is enthusiastic in its praise.

---

[1] *Industries.*

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED APRIL 19, 1892.

Accumulators:—

Secondary Battery, H. E. Dey, 473,146. Filed Sept. 10, 1890.

Claim 2 follows:

A negative plate for secondary batteries composed of finely divided or spongy lead having its edges compressed or compacted and raised above one face, forming a flange or protecting edge along the sides and bottom of the plate.

Secondary Battery, H. E. Dey, 473,147. Filed Sept. 17, 1890.

Claim 1 follows:

The combination in a secondary battery with the positive and negative plates of the same, of metallic partition plates interposed between contiguous active plates and provided with thickened or flanged edges and packing between the edges of said partition plates.

Alarms and Signals:—

Signaling System, H. A. Chase, 472,983. Filed Nov. 6, 1891.

A signaling system capable of transmitting a given number in a series of short impulses and a series of long impulses whereby two distinct purposes may be indicated.

District Telegraph Box, C. Selden, 473,024. Filed June 15, 1885.

Consists in the combination with a district signal apparatus of an indicator operated by an electromagnet having two coils connected respectively with the line and the ground circuit.

Electrical Annunciator, T. W. Lane, 473,121. Filed Dec. 15, 1890.

Employs an electrical set-back composed of a magnet, armature having a spring connection, supporting posts therefor and a suitable locking device.

Railway-Signal, U. S. Jackson, 473,190. Filed Oct. 21, 1891.

Anelectric block system, adapted to be operated both mechanically and electrically.

Electric Railway Signal, J. M. Brasington, 473,288. Filed July 24, 1891.

A signal for a locomotive cab adapted to warn the engineer of a break or obstruction on the track.

Conductors, Conduits and Insulators:

Conduit and Trolley for Electric Railway Systems, S. C. Carll and J. W. Phillips, 472,982. Filed Feb. 19, 1891.

A double-wire conduit and trolley for electric railways.

Conduit for Electric Wires, C. H. Wilson, 473,044. Filed Sept. 19, 1889.

Claim 8 follows:

A subway for electric conductors formed of sections of pipe, the different sections being joined by a flexible joint and a T forming a part of said pipe, in combination with a lateral extending from said T.

Electric Cable, W. H. Sawyer, 473,267. Filed Oct. 27, 1891.

Consists of a series of wires interbraided with fibrous material into tubular form.

Electric Cable, W. H. Sawyer, 473,351. Filed Oct. 27. 1891.

Similar in construction to No. 473,267, but having an air-space through the centre.

Electric Cable, W H. Sawyer, 473,352. Filed Oct. 27, 1891.

Similar to No. 473 351.

Electric Cable, W. H. Sawyer, 473,353. Filed Oct. 27, 1891.

Similar to No. 473,351.

Dynamos and Motors:—

Armature Core for Electric Motors, D. Pepper, Jr., 473,077. Filed July 24 1891.

A core built up of sections, having at their ends tongues and enclosed recesses with a spider having arms arranged to grasp and centre the interlocked sections.

Armature Ring, D. Pepper, Jr., 473,078. Filed Dec. 3, 1891.

An armature ring adapted for use in connection with the core described in No. 473,077.

Commutator Brush, G. Meyer, 473,195. Filed June 6, 1891.

Commutator brush having various independent points of contact, flexibly secured so that the breaking of one will in no way affect the other for the purpose of preventing sparking and wearing of the commutator.

Armature for Dynamo-Electric Machines, S. H. Short, 473,363. Filed June, 10. 1891.

Employs a foundation ring grooved circumferentially on its inner periphery and a laminated core, a portion of the folds of which are of less width than that of the foundation ring.

Armature for Dynamo-Electric Machines, S. H. Short, 473,364. Filed June 19, 1891.

Claim 2 follows:

An armature for a dynamo electric machine provided with a branch conductor for a commutator connection united to the bobbin wire by a flat line joint which leaves the bobbin wire practically continuous for winding.

Armature for Electric Generators or Motors, S. H. Short, 473,366. Filed June 24, 1891.

A tooth armature having magnetic material projecting over the outside of the rectangular bobbin recesses so that a narrower slot is left between them through which the bobbin wire may be introduced for winding.

Dynamo-Electric Machine, S. H. Short, 473,367. Filed June 24, 1891.

Claim 1 follows:

A dynamo-electric machine having the armature turning in sliding contact with the field poles.

Galvanic and Thermo-Electric Batteries:—

Electric Battery, J. E. Emley, 473,386. Filed Jan. 27, 1891.

Claim 2 follows:

In an electric battery an electrode formed of two discs arranged parallel with each other and suitably secured together, an electrode of opposite polarity, consisting of a disc mounted upon a shaft and arranged to rotate between the discs of the first-named electrodes, means of rotating said shaft and means for conducting the electricity from the electrodes,

Lamps and Appurtenances:—

Electric Arc Lamp, O. Patin, 473,076. Filed April 11, 1891.

An arc lamp adapted to work either in series or shunt and with continuous or alternating currents, and producing the lighting and regulating by means of a simple coil mounted in shunt with the poles of the arc.

Incandescent Electric Lamp, A. C. Carey, 473,208. Filed Dec. 1, 1891.

Provides means for renewing the carbons of incandescent lamps when broken.

Rheostat, A. C. Carey, 473,209. Filed Jan. 27, 1892.

Provides means for controlling the brilliancy of incandescent lamps by interposing rheostats in the individual circuits.

Electric Light Support, G. M Kim, 473,229. Filed Oct. 10, 1891.

Lamp Shade and Holder for Incandescent Lamps, G. F. Seavey, 473,240. Filed Aug. 6, 1891.

Electric Arc Lamp, T. E. Adams, 473,283. Filed July 8, 1890.

Has for its object to provide an adjustment that will remain fixed and certain for any given current and cannot be changed or modified by the trimmer or attendant.

Incandescent Electric Lamp Socket, C. R. Arnold, 473,373. Filed Dec. 17, 1891.

A spring socket for incandescent lamps subjected to vibration or jar.

Metal-Working:—

Heating and Welding by Electricity, H. Howard, 473,003. Filed Oct. 21, 1891.

A welding system in which the material to be welded forms one pole, and a pencil the other pole of an electric arc.

Metallurgical:

Electrode, P. L. T. Heroult, 473,398. Filed Aug. 8, 1889.

An electrode for metallurgical works consisting of carbon, a plate of metal extending its entire length and means for fastening them together.

Method of Producing Metallic Zinc, P. C. Choate, 473,186. Filed Jan. 5, 1891.

Consists of forming an electrolytic solution by dissolving in dilute sulphuric acid oxide of zinc in the state of fume free from the lighter soluble impurities and then treating the solution by electrolysis.

Apparatus for Producing Aluminum or other Metals, P. Heroult, 473,118. Filed Dec. 27, 1887.

Electrode for use in Electro-Metallurgical Processes, P. Heroult, 473,117. Filed Sept. 8, 1889.

Consists of carbon strips secured together in a single block and a metal combined therewith in order to lower the electrical resistance of the electrode when in use.

Electrolytic Apparatus for Separating Gold and other Metals from their Ores, G. J. Atkins, 473,105. Filed Apr. 28, 1891.

Ore Separator, S. G. Elliott, 473,066. Filed Aug. 19, 1890.

Miscellaneous:—

Electric Clutch, P. W. Willans, 473,042. Filed July 21, 1891.

Contains an iron ring provided with a series of horns having metal rings of low resistance, circuit windings between the horns and an iron cross-head rotating within the ring and having circuit wires wound upon its opposite extremities parallel to its axis of rotation.

Lightning Arrester, M. M. Wood, 473,045. Filed June 20, 1891.

Consists of a ground wire and a wire leading to the line.

Claim 1 follows:

The combination of a ground wire with a wire leading to the line and a connecting circuit from line to ground, consisting in part of a substance of high resistance and a substance of low resistance, the two opposed to each other and the one substantially surrounding the other.

Electric Lock, C. H. Crockett and C. C. Allen, 473,061. Filed May 5, 1888.

Machine for Making Insulated Magnetic Coils, C. E. Lipe, 473,123. Filed Oct. 8, 1890.

Electro-Therapeutic Heating Pad, F. H. Soden, 473,133. Filed Sept. 1, 1891.

Ship's Log, R. T. Hall, 473,222. Filed Sept. 7, 1891.

Consists of a flexible diaphragm below the water line, a resistance coil, connections between its pole-pieces and the diaphragm, an electric generator and an indicating device for the variations of resistance.

Electric Odometer and Speed Indicator, W. A. Phillips, 473,341. Filed March 19, 1891.

The combination with the anchor or detent of the escapement wheel of the register-hand-actuating-gear mechanism, the armature lever having one end normally resting upon said anchor at its elevated end, and an electromagnet having electrical connection with the car wheel axle.

Electric Stop Motion for Looms, J. C. Brooks, 473,378. Filed May 14, 1891.

Railways and Appliances:—

Hanger for Electric Wires, T. Imeson, L. D. Tibbets and C. L. F. Kellogg, 473,158. Filed Feb. 2, 1892.

A trolley-wire hanger consisting of two interlocking jaws in combination with a pivot plate.

Converter System for Electric Railways, M. W. Dewey, 473,253. Filed June 25, 1889.

See THE ELECTRICAL ENGINEER of April 20th.

Multiple Arc Railway System, S. H. Short, 473,361. Filed Jan. 8, 1890.

Provides a series of independent blocks of conductor and automatic cut-out devices combined with each block.

Trolley Switch, S. H. Short, 473.362. Filed Jan. 8, 1890.

An automatic switch operated by the trolley itself.

Gearless Motor for Electric Railway Cars, S. H. Short, 473,365. Filed June 24, 1891.

Relates to street car motors in which the armatures are axially placed with reference to the driving axles and directly connected therewith.

Gearless Propelling Mechanism for Electric Railway Cars, S. H. Short 473,368. Filed July 6, 1891.

Claim 1 follows:

The propelling mechanism for an electric railway car comprising, in combination with the driving axle, an armature mounted on said axle and rotating therewith, and field magnets provided with journal bearings at the periphery of said armature.

Switches and Cut-Outs:—

Electric Switch, F. H. Soden. 473,132. Filed July 2, 1891.

Permits a ready and convenient use of a hand-operating switching device in connection with any desired number of contacts.

Electric Switch, F. H. Soden, 473,134. Filed Oct. 26, 1891.

Similar in its object to 473,132.

Electric Switch, E. H. Johnson, 473,228. Filed Aug. 25, 1891.

A switch designed especially for currents of considerable quantity and high tension; the construction being such that dangerous heating is practically impossible for the reason that should the contacts begin to heat they become more firmly pressed together by the expansion of the metals, thus automatically increasing their carrying capacity.

Cut-Off for Electrical Machines, J. P. Woolley, 473,282. Filed Nov. 23, 1891.

Claim 1 follows:

The combination with an electromagnet, of a weight normally suspended under, and supported by, said magnet and a cord passing over pulleys and connecting to a circuit breaker.

Electric Switch, E. P. Warner, 473,435. Filed Feb. 2, 1889.

Consists of two pairs of springs mounted on the opposite side of an insulating block and a pivoted shifter whereby either pair may be separated from the lamp circuit terminals and connected together, while the other pair close upon the terminals.

Telegraphs:—

Electric Indicating System and Instrument, H. J. Haight, 473,174. Filed Dec. 15, 1891.

A system for the purpose of enabling the transmission of a variety of data concerning each of several subjects.

Telephones and Apparatus:—

Testing Apparatus for Trunk-Lines of Telephone Exchanges, C. E. Scribner, 473,089. Filed March 13, 1885.

Enables the operator wishing to connect with a trunk-line to make a quick test to determine what trunk lines are free.

Telephone Receiver, E. C. Hess, 473,256. Filed July 1, 1891.

A receiver adapted to be applied to both ears at once.

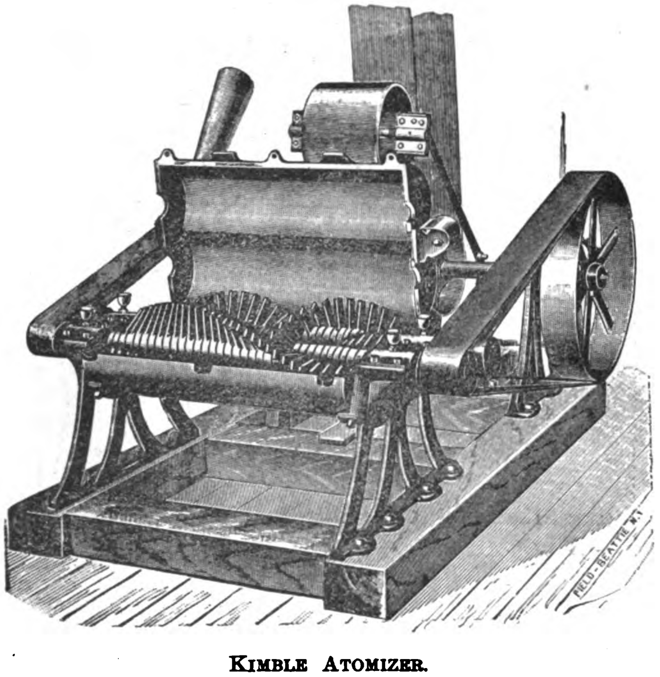
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

An ad. is a good search light to find new customers with.

THE KIMBLE ATOMIZER.

We present on this page an excellent cut of the Kimble atomizer showing its interior very accurately. The atomizer is set up with back countershaft and tightener and is belted ready to attach power. The power required to run one machine is about 10 h. p. The space occupied by the machine is about 5 feet by 7 feet. Attention may be called to the two shafts upon which are set a number of beaters or fingers. These are made of a superior grade of gun-metal. A key seat is cut in each beater, they are then put in place and firmly fastened with a nut holding them firmly. It will be noticed that the belt on shaft No. 1 in running rides off shaft No 2, both running in the same direction and at a speed of 6,000 revolutions per minute. The fingers on shaft 2 in revolving pass through the fingers on the other shaft and *vice versa*. On shaft 2 the fingers are placed spirally, giving them a tendency to carry the material from left to right in the machine at a velocity of 18,000 feet per minute; while on shaft 1 the fingers are put on the reverse way, carrying the material in the opposite direction at a velocity of 9,000 feet per minute. It will be seen by this that we have two opposing parts running in opposite directions at a wonderful velocity. This machine is an almost indispensable article to those whose business necessitates the atomizing of mica, asbestos, graphite, carbon, aluminum earths, oxides. etc. The R. R. Mica Lubricant Company, 444 Pearl street, New York, are the manufacturers and furnish a nicely illustrated and descriptive catalogue.



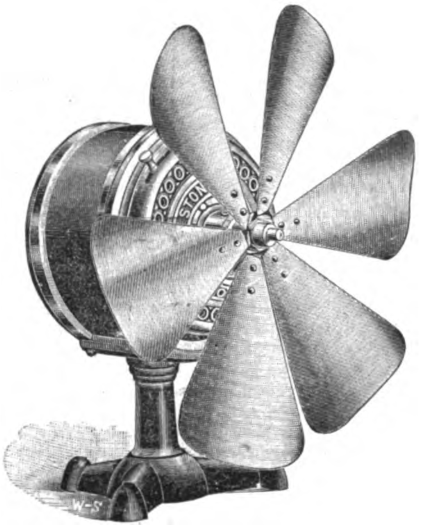
Kimble Atomizer.

THE MESTON ALTERNATING FAN MOTOR.

The accompanying illustration shows the 1892 model of the Meston alternating fan motor, manufactured by the Emerson Electric Mfg. Co., of St. Louis. The fan is 12 inches in diameter, and has a variable speed up to 2,000 revolutions per minute. The motor takes a current of 1.8 ampere and runs on a 52-volt circuit. It is finely finished in polished bronze and black enamel, and is thoroughly artistic in design. The base or stand is a graceful tripod, furnished with soft-rubber cushions, which gives a secure footing for the motor, and prevents all noise by vibration.

The polished bronze castings which serve as bearings for the armature shaft, are of highly ornamental design, and are extremely strong and substantial. The motor is completely enclosed, no wire being visible, nor any of the working parts exposed to possible injury. At the same time it is easily accessible, as the end covers may be removed entirely in a moment, and the armature taken out without disconnecting any wires or disarranging any adjustment.

The regulating device is exceedingly simple. Not only can the speed and the consumption of current be varied instantly at will, but the direction of rotation can be changed by a further movement of the same button. The armature, commutator, brushes and holders are of the finest workmanship and are made to last, while the self-oiling bearings form a special feature of the motor, and cannot throw oil.



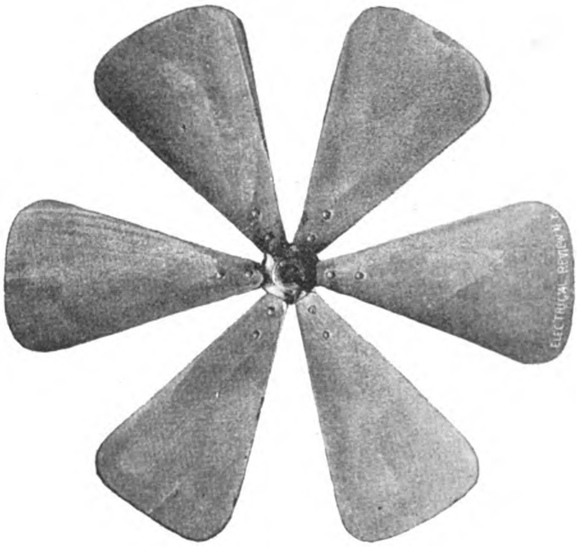
Meston Alternating Fan Motor.

The Emerson Electric Mfg. Co. are overrun with orders for this fan, and have been compelled, thus early in the season, to increase their facilities.

THE HOLMES, BOOTH & HAYDENS BALANCED FAN.

The accompanying illustration shows a brass fan for electric motors, recently introduced by Messrs. Holmes, Booth & Haydens, of this city, and Waterbury, Conn.

Experience has been availed of, to produce a fan that will distribute the breeze from it, and not throw it out like a gleam from a search light, as many fans do. The high speed of a motor fan requires absolute mechanical efficiency to ensure safety, and as these fans are finished by the lamp department of Holmes, Booth & Haydens, an elegance is secured which makes them decidedly ornamental. They are of all sizes from 5 to 15 inches, and lacquered, or silver-plated. Fan guards are also made for any size of fan.



Balanced Electric Fan.

THE STEARNS MANUFACTURING CO.

We learn that the Stearns Manufacturing Co., of Erie, Pa., have now acquired by purchase the remaining franchises of Woodbury, Booth & Pryor and the Woodbury Engine Co., of Rochester, N. Y., including all patterns, patents, special tools, trade marks, good-will, etc., etc. This puts into the hands of the Stearns Company not only the sole ownership of the Woodbury high-speed automatic steam engines, which they previously purchased, but also the "Woodbury Medium-Speed Automatic Engines" and the means of producing both.

The name "Woodbury" has been for forty years synonymous with good steam engines, and with something over three thousand of the two classes here named, all bearing the "Woodbury" earmarks, to point and refer to, the Stearns Company ought to be satisfied they have made no mistake in adding the medium-speed automatic Woodbury to the Woodbury high speed they have already pushed to the front rank of its class.

THE "VICTOR" CYLINDER AND REGISTER GATE TURBINES.

The electrical transmission of power over long distances gives an immediate value to water-powers, which have hitherto remained unimproved because located more or less remotely from transportation lines, or because the local demand for power was not sufficient to justify the expense. The country abounds in such water-powers, many of them of immense magnitude, and it is only a question of time when they will be improved and the power generated, transported by wires to the surrounding cities and towns utilized for light, heat and power. In view of these facts a new and increased interest attaches to the question of turbines, their construction and application.

With a commendable determination to meet all reasonable demands of customers, and maintain their position as manufacturers, the Stilwell & Bierce Manufacturing Company, of Dayton, Ohio, have perfected and introduced their "Cylinder Gate" Victor turbine, which has been carefully tested in the Holyoke testing flume with gratifying results, not only as to high efficiency but as to power, which was proved to be larger for its diameter than any other known turbine. The tests also developed a remarkably high efficiency at all degrees of gate opening, from one-half to full gate.

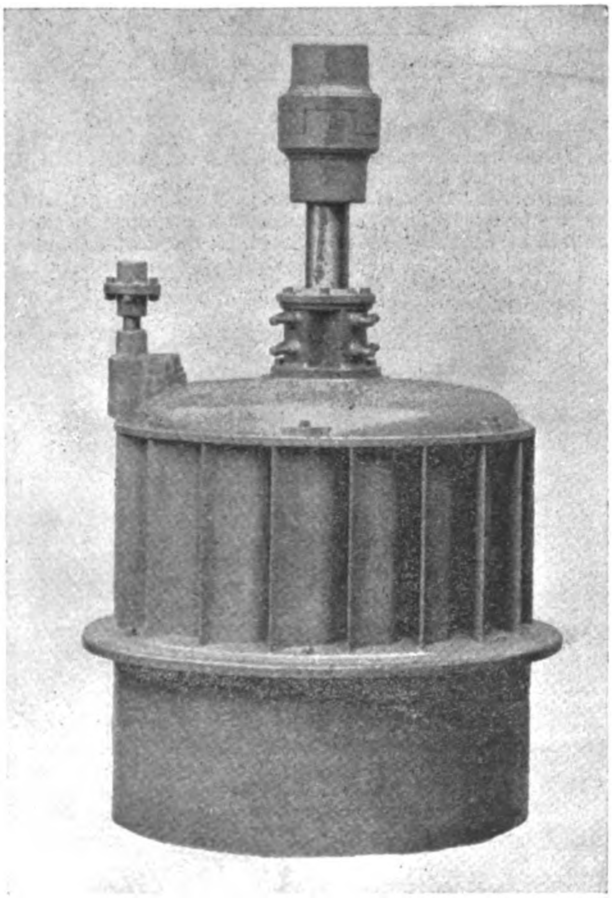


Fig. 1.—The "Victor" Cylinder Gate Turbine.

The accompanying illustrations show both styles of the "Victor" turbine made by this company, Fig. 1 showing the "register gate" and Fig. 2 the "cylinder gate." A separate catalogue is published for each one of these wheels, and will be furnished by the manufacturers to interested parties on application.

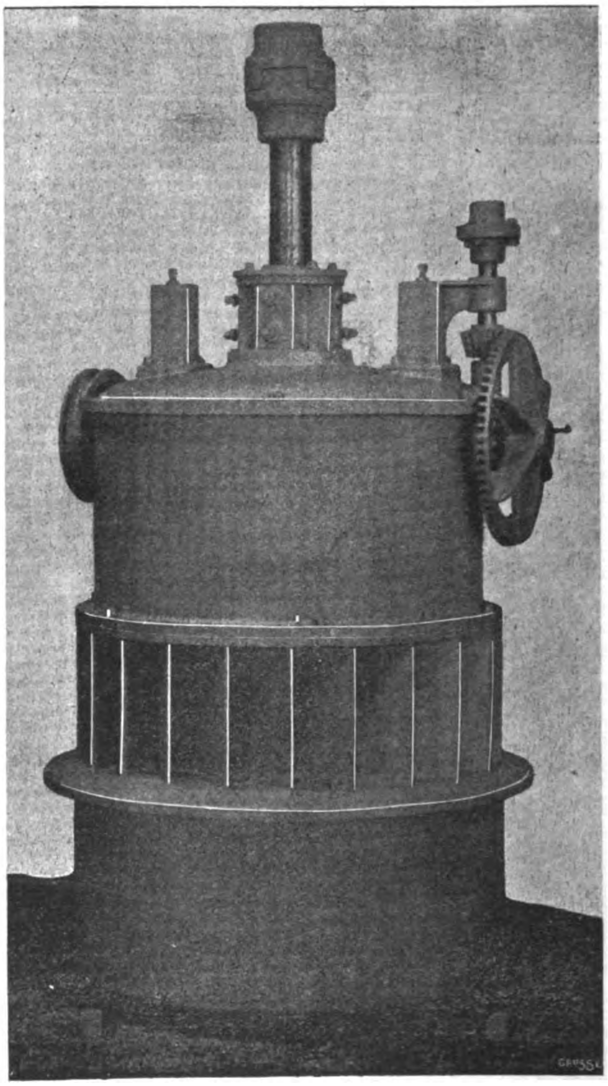

Fig. 2.—The "Victor" Register Gate Turbine.

These turbines are built in sizes ranging from six to sixty inches in diameter, on vertical or horizontal shafts, in a great variety of plans adapted to all classes of establishments, from the simple country mill requiring 50 h. p. or less up to the mammoth cotton mills, paper mills or electric plants, consuming many thousand horse power. The Stilwell & Bierce Manufacturing Company are also provided with a very complete assortment of patterns of all kinds of modern appliances for transmitting power, and make a specialty of complete water-power plants for all purposes.

A "SHORT" RAILWAY PLANT FOR SIAM.

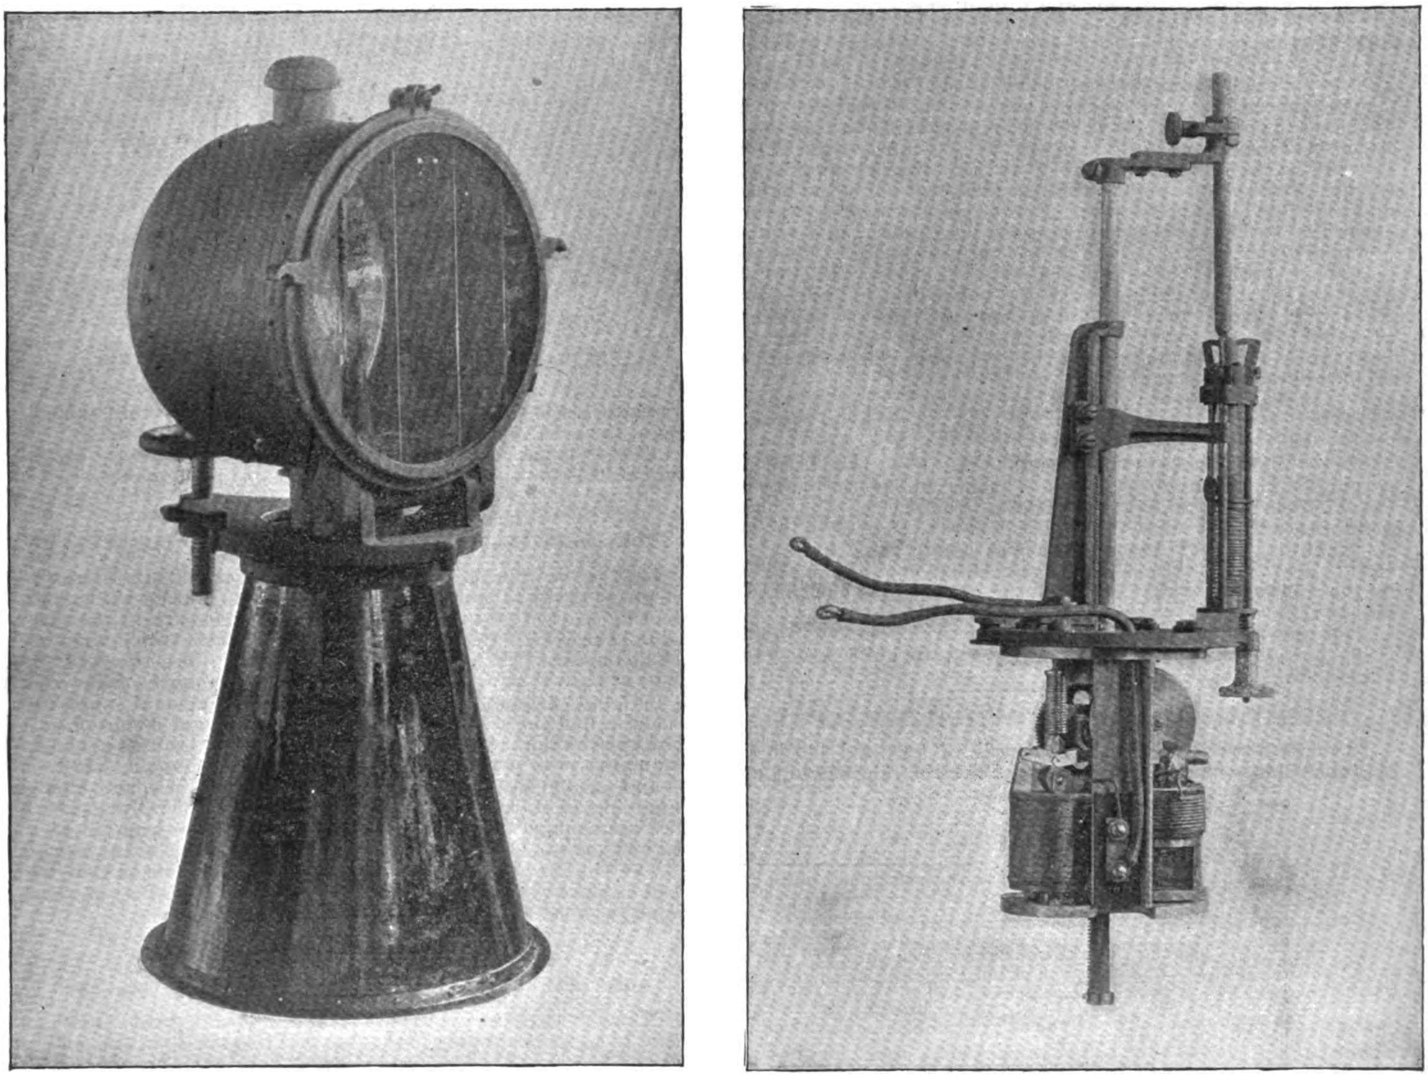
The Short Electric Railway Co. are now shipping to Siam the entire installation for the first electric tramway in that country. The plant goes to the Bangkok Tramways Co., who will equip a road 6 miles long, 6 foot gauge. The road is practically level and most interesting throughout its entire length, crossing fourteen of the many canal bridges in Bangkok. Teakwood poles will be used in construction throughout—in fact, all wood used in connection with the installation will be teakwood. The plant includes two generators, two steam plants complete, six car equipments and extra parts to last for six months.

The order is the outcome of the visit to this country of Mr. Aage Westenholz, who made a thorough examination of electric railway apparatus, both in Europe and in this country, visiting all the large manufacturing companies and the most succesful of their plants. Mr. Westenholz is the leading engineer in Siam.

NEW EDISON SEARCH LIGHT PROJECTOR.

WE give below description and illustrations of the new "D" type search light projector, recently designed by the Edison General Electric Co. Fig. 1 shows the side and front view, and Fig. 2 the lamp mechanism, which will give a good idea of the general style of the projector.

The lamp is designed to run on an incandescent circuit with a potential of 50 to 55 volts, at which it requires about 15 amperes and gives a light of 3,000 c. p. A suitable resistance is placed in series with the lamp to permit of its adjustment to the potential of different circuits upon which it may be used. The lamp is both self-regulating and self-focusing. The lower carbon is pressed upwards against fixed stops by a spiral spring, thus maintaining the arc in the focus of the reflector. A hand adjustment is provided for raising and lowering these stops, by which the vertical position of the arc can be altered. The upper carbon falls by gravity, its descent being perfectly regulated by the lamp mechanism, so that great steadiness of light is obtained. The negative carbon being placed a little back of the line of the positive carbon, a crater is thus formed on the side of the latter and nearly all the light is thrown toward the reflector. A ventilating hood on the top of the drum provides an escape for the heat.



FIGS. 1 AND 2.—NEW EDISON SEARCH-LIGHT PROJECTOR.

The drum is of iron and 18 inches in diameter. A highly polished silver plated parabolic reflector 17 inches in diameter, with five-inch focus is mounted at one end of the drum on a finely threaded screw-piece, by which it can be moved to or from the arc. By this means the light can be concentrated in a narrow beam or be widely diverged. The usual focus in projectors of this class is from two inches to three inches, and considerable advantage is derived by the increase in focus obtained in this projector. A fine hole is drilled through the screw-piece on which the reflector is mounted, through which the exact position of the arc is shown on a small piece of ground glass.

The drum is provided with vertical and horizontal adjustments. The vertical adjustment is effected by means of a hand wheel operating a double-threaded screw. It has a vertical movement of 30 degrees, 15 degrees above and 15 degrees below the horizontal line, which is sufficient for ordinary purposes. The horizontal adjustment permits a complete revolution of the drum upon its base, so that the light can be readily thrown toward any point of the compass. By means of a clamp screw the drum can be quickly fastened in any position.

Provision is made for a cord attachment in order that the projector may be operated from a distance if preferred, as for instance from the pilot house, when the projector is set at the bow or any other part of a vessel. The connecting terminals for the lamp are placed on opposite sides of the drum; the conductors can therefore be brought up in the form of spirals without risk of their "crossing."

The height of the projector is 48½ inches and the centre of the reflector is 36 inches above the bottom of the base. The floor space required for the base is 22 inches in diameter. This projector is simple, strong and substantial, and all the parts have been arranged with a view to secure efficient and easy operation. It is estimated that in clear weather the beam of light will have an effective range of 2,000 yards. The compactness of the entire apparatus renders it especially advantageous for use on vessels, wharfs, etc.

BIDS WANTED FOR AN ELECTRIC RAILWAY AT NIAGARA.

MR. W. T. JENNINGS, engineer, informs us that on Monday, May 2, plans, profiles and specifications will be on exhibition at the office of the Niagara Falls and River Railway, Niagara Falls, Ont., upon which tenders will be received up to May 10, 1892, for the complete electrical equipment of the line as far as at present required.

BLOCK SIGNALS ON THE NEW YORK CENTRAL.

An important step and one that is certainly in the right direction has been taken by the management of the New York Central and Hudson River Railroad. This is the adoption of a complete system of block signalling over their entire line between New York and Buffalo. After months of the most careful consideration and experimenting, they have finally decided upon the systems of signals they will use as more or less adapted to different portions of their lines. Contracts have been let, and the work is well under way. Mr. Theo. Voorhees, general superintendent of the New York Central, states that the contract for the work between this city and Poughkeepsie has been let to the Johnson Railway and Signal Company, and that portion between Poughkeepsie and Albany to the Union Switch and Signal Company. That portion of the company's lines between Albany and Buffalo required very careful consideration on account of the great amount of freight handled there. After special trips over this particular part of the system, a general plan of operations was decided on. It is proposed to establish absolute block stations for the passenger tracks between Albany and Buffalo at a distance of about three miles apart. These same stations will be used as a block for all freight tracks over the greater part of the entire distance. At each end of the divisions and at the approach to large yards, auxiliary electric signals will be placed on each side of the freight tracks between the signal stations, causing those portions to be operated under what might be termed a permissive block system. Between Albany and Buffalo there will be ninety-three signal stations, seventy-three of which will be iron bridges spanning the tracks. These will be light structures, and will carry the signals and the cabin of the operator. Every operator's cabin over the entire line will be equipped with Sykes instruments and will be operated under what is known as the "Sykes system." The system is expected to be completed between Albany and Buffalo about the month of August, and the entire line by the first of November. This work is to cost several hundreds of thousands of dollars, and the traveling public can now rest assured that the best known and absolute systems of protection will be installed regardless of their cost.

THE WADDELL-ENTZ CO.

The Waddell-Entz Electric Co., has just been incorporated in the State of West Virginia under the name of the Waddell-Entz Co., with a capital of $5,000,000. The incorporators are Montgomery Waddell, J. B. Entz, W. A. Phillips and A. Knauth. In 1890 the concern was incorporated under the statute laws of the State of New York with a capital of $100,000. Of the $5,000,000 capital stock of the new company, $2,500,000 will be represented by cash and $2,500,000 by patents.

It is proposed to greatly enlarge the factory of the company in Bridgeport, Conn., and, if found necessary, to build a new one altogether.

TERMINAL BLOCK FOR STATION SWITCHES.

The cuts herewith shows a new style of terminal block for station switches manufactured by the Electric Engineering and Supply Company, of Syracuse, N. Y. The wires are all brought in from the back, none whatever showing in front of the slate base, thus adding greatly to the neat appearance of the switch, and to the ease with which the wires can be inserted or withdrawn from the terminal blocks.

To insert the wire into the terminal, one has only to loosen the set-screw, and draw out the hollow terminal plug and solder the wire into it, when it can be readily pushed into the terminal block again, the set-screw tightened, and the operation is complete.

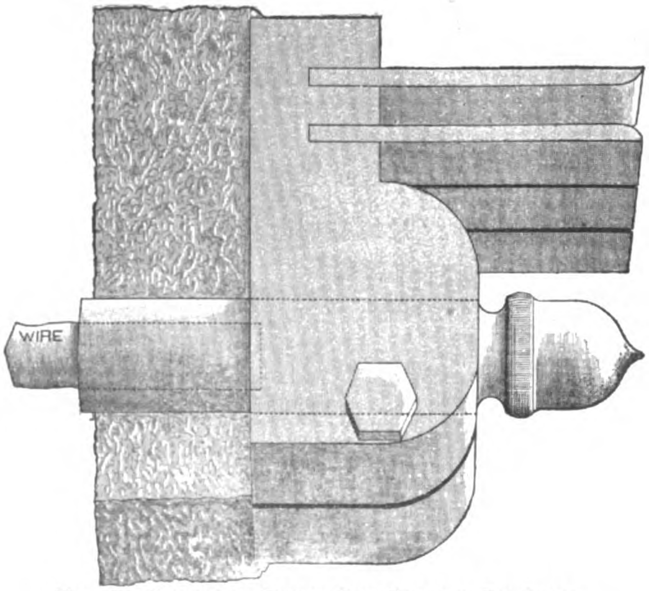


Fig. 1.—Terminal Block For Station Switches.

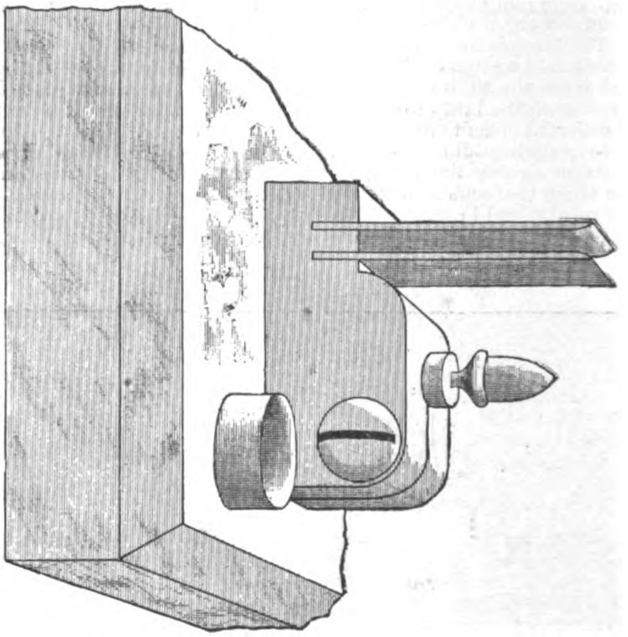

Fig. 2.—Terminal Block For Station Switches.

This style of terminal is now used by this company for all sizes of station switches from 35 amperes to 1,000 amperes.

A STORAGE BATTERY STATION AT HAVERFORD COLLEGE, PA.

Last week we published an editorial article with reference to the growing use of storage batteries in central station work, commenting on the fact that so little had been done here in the same field. The *Western Electrician* of April 30, has a very interesting article on the subject, with special details and illustrations of the plant at Haverford College, Pa. This plant was started as far back as 1887, but early sustained reverses, and the general inpression has been that the storage plant was in a moribund condition. It now appears that although the underground cables used as charging mains have virtually been abandoned, the company has gone on and during the last year has built overhead lines, and is now supplying about 3,000 lights. The batteries are generally placed in the basements of the houses, and each set supplies from three to ten residences. The batteries of the Accumulator Co. and apparatus of the Electro-Dynamic Co. are used. The success that has been attained with this small plant is a fair indication of what might be expected on a larger scale.

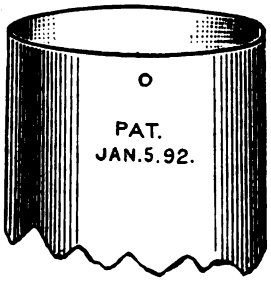
ELECTRIC RAILWAY DEVELOPMENT IN NEW ORLEANS.

New Orleans is practically the last of the great American cities to adopt the trolley, but it has had to come to it, and a large plant is now to be put in by the New Orleans and Carrollton Railroad Company. The road will be several miles long, and the change from mules will be made as quickly as possible. The electrical equipment will comprise 50 cars of the Thomson-Houston system, the cars being supplied by the St. Louis Car Company. Girder rails, 72 pounds, Johnson make, will be supplied by W. Kington, of Atlanta; 50-pound T-rail by the Pennsylvania Steel Co.; and 60-pound duplex by the Duplex Rail Company. The overhead construction will be done by J. G. White & Co., of New York, and the Ansonia Company's wire will be used. The steam plant will include three Corliss engines of 300 h. p. each. J. Hernandez is president of the road; W. V. Crouch, secretary; and C. V. Haile, superintendent. The consulting engineer for the whole work is Mr. A. Langstaff Johnston, who has already done so much of the best electric railway construction in the South.

Congdon, Bliss & Daniels, of Washington, D. C., have taken the agency for the Dayton Fan and Motor Co., of Dayton, Ohio, and have already sold about $1,600 worth of these motors during the past four weeks, ranging in size from one to four horse power.

THE HOLE IN THE JAR.

We show herewith a little patented device, controlled by Messrs. J. Jones & Son, of this city. The idea, while simple, is of value, and is used on all gravity cells put out by this company. It is only a hole drilled in the side of the battery jar, through which passes the wire attached to the copper in the cell. This hole prevents any strain to which the wire may be subjected, being communicated to the copper, and effectually prevents the displacement of the electrode. This renders the elements of the battery permanent at all times. Of course in upsetting the battery when it is to be refilled, this device plays no part at all.



"The Hole in The Jar."

KEYSTONE ELECTRIC CO.

Although the activity of large electric manufacturing concerns in the East and West is well known, people are quite likely to underestimate the amount of work turned out and the large number of important sales made by companies whose headquarters are in neither New York nor Chicago. The Keystone Electric Works of Erie, Pa., for instance, are meeting with surprising success, and now that they have launched upon the market a practical reversible elevator motor, it is more than likely that it will be necessary to increase their facilities in order to keep up with their orders. The reversible elevator motor, manufactured by this company, having carbon brushes and running directly connected to elevator mechanism, using no rheostat, is attracting wide and favorable attention from both the makers and users of elevators. Not until a recent visit to Erie by one of our staff did The Electrical Engineer adequately appreciate the size of the business done by the Keystone Electric Works, a business which will be partially indicated by the following list of motors ordered and shipped since Jan. 1, Manager Leech and Electrician Sturgeon are proud of this record, as they may well be:

Marshall Bros., Pittsburgh, 5 h. p. reversible; C. S. Knowles, Boston, Mass., 10 h. p. reversible; John J. O'Brien, Erie, Pa., 3 h. p. shunt for printing office; Erie Electric Motor Co., Erie, Pa., 5 h. p. motor 500 volt for running shops; Jamestown Electric Light & Power Co., Jamestown, N. Y., 2 h. p., for shirt factory; F. W. Brody, N. Y. City, 5 h. p. reversible, elevator; F. P. Jones & Co., Buffalo, N. Y. 3 h. p. shunt, ¼ h. p. reversible, 2 h. p. shunt, for fans, 2 h. p. compound; E. A. Sarran, Cincinnati O., ½ h. p. compound, ¼ h. p. reversible, ¼ h. p. compound, fan; Peninsular Electric Co.. Grand Rapids, Mich., ¼ h. p. reversible; Marcus Ruthenburg, New Albany, Ind., 1 h. p. reversible; Graves Elevator Co., Rochester, N. Y., 10 h. p. reversible, elevator; Marple Engineering Co., Detroit, 5 h. p. reversible; E. J. Reblet, Erie, Pa., 5 h. p. reversible, elevator; McKinnon Iron Works, Ashtabula Harbor, O., 50 light dynamo; Despatch Publishing Co., Erie, Pa., 7½ h. p. shunt for printing; S. B. Harnon, Williamsport, Pa., 1 h. p. compound motor for fans; Hunt & Connell, Scranton, Pa., 1 h. p. compound motor for fans; George Leonhart, Warren, Pa., 1 h. p. shunt motor, fans; Albert Will, Rochester, N. Y., 3 h. p. shunt motor; J. F. Gebhardt, New Albany, Ind,, ¼ h. p. motor, fans; Harris Bros., Jamestown, N. Y., 2 h. p. shunt motor; Jamestown Street Railway Co., Jamestown, N. Y., 10 h. p. shunt motor; C. J. Frank & Co., Cincinnati, O., 3 h. p reversible, elevator, ½ h. p. compound for coffee mill; H. M. Seitzinger, Wilkesbarre, Pa., ¼ h. p. compound, fans; H. J. Reedy Elevator Co., Cincinnati, for Anderson, Ind., 7½ h. p. reversible elevator; Bigelow Electric Supply Co., Lincoln, Neb., one 5 h. p., one 3 h. p., one 2 h. p., one 1 h. p., one ½ h. p. and one ¼ h. p.; Jamestown Electric Light Co., New York, ¼ h. p., ½ h. p., 1 h. p., 2 h. p.; Dr. F. H. Able, Erie Pa., ¼ h. p. for dental work.

AMERICAN DISTRICT STEAM CO.

The American District Steam Co., of Lockport, N. Y., report an increased and increasing correspondence on the subject of the use of exhaust steam from central stations since The Electrical Engineer's recent articles upon that subject. It is becoming obvious to a great many electric lighting and power stations that heat units are being thrown away in exhaust steam during the cool and cold weather which would have a ready and profitable market were a satisfactory system adopted for the use of exhaust steam for heating purposes in the vicinity of stations. The system of the American District Steam Co. has already made a paying success out of more than one central station that has hitherto been unprofitable in lighting and power alone. Mr. I. H. Babcock, treasurer of the American District Steam Co., of Lockport, N. Y., is only too glad to keep up with his growing correspondence on this subject, and believes he sees a way to be a benefactor to the electric lighting and power industry in general.

JONES BROS. & CO.

One of the most notable features of the World's Fair, in Chicago next year, will be a complete model of the entire plant of the H. C. Frick Coke Company, of Scottdale, Pa. This company employs about forty million dollars capital in its business, and is the largest of the kind in the world.

The contract has been let to the Jones Bros. Company, of Cincinnati, Ohio, who are experts in the making of models. The estimated cost of this model is between three and four thousand dollars.

The plant will occupy a space about 20 x 50 feet made on a scale of one-twentieth of an inch to the foot, and will be an exact fac-simile of the original, including boilers, engines, piping, elevated tracks, cupolas, cars and all other machinery and will be in operation. The motive power, however, will be electricity.

NEW YORK NOTES.

The Onandaga Electrical Co., of Syracuse, N. Y., have just purchased five Wood 80-light arc machines, making a total of 400 arc lights, together with 4,500 Slattery alternating and 2,000 Edison three-wire incandescents. They will install four 325 h. p. McIntosh & Seymour tandem compound engines, and four 125 h. p. Wood street railway generators. The company will supply power to the People's Street Railway Co., and will install seven boilers of the Phœnix Iron Works, of Syracuse, of 150 h. p. each. The officers of the company are as follows: W. B. Kirk, president; J. E. Palmer, secretary, (president of the People's Street Railway Co.) and Messrs. Kirk, Palmer, Belden, Myers, Barnes, P. B. McClellan, John McLennon, W. A. Andrews and R. T. McDonald, trustees. The electrical equipment of the plant was ordered through Mr. W. J. Morrison, New York State agent of the Ft. Wayne Electric Co.

Mr. Frank R. Chinnock, one of the most active of the electrical men in this part of the country, and for many years a highly successful representative of the Edison interests, has now carried his energies and aggressive personality into another field. He has become the agent of the Ball Engine Co., of Erie, Pa., and will have full charge of their New York work, etc., with headquarters at 18 Cortlandt street. It is rarely that so well-known a man and so popular an engineering specialty are thus brought together, and the best results may be looked for. Mr. Chinnock's work of late years has given him a thorough insight into the engine and steam business, and he has the further advantage of knowing the needs of the electric light and power industry in a very special manner.

The Interior Conduit and Insulation Co. have issued a superb catalogue, No. 7, of their various excellent productions and specialties. It has all the familiar artistic taste and finish of publications from the Bartlett Press, and is, moreover, admirably arranged. The text is also judicious and helpful. The growth of the business of the company is shown by the fact that this catalogue is in large quarto form and fills 46 pages. It has an ornamental cover in tints of blue.

Mr. Ralph A. Schoenberg, with The E. S. Greeley & Co, 5 and 7 Dey street, has just returned from a Western trip, during which he has established agencies for his "Pneumatic annunciator reset," with such well known concerns as the Central Electric Co., of Chicago; the Electrical Supply Co.; Detroit Electrical Works, Standard Electric Co., of Cincinnati, and Cleveland Mfg. Co., of Cleveland, O.

Mr. Albert E. Davis, manager of the advertising department of *Electric Power*, has resigned his position. He will now have control of the advertising of the Dr. Bury Medical Co. and the Covert Manufacturing Co., both of West Troy, N. Y., where he will hereafter have his headquarters.

The Brush Electric Co. have removed their Eastern offices from 115 Broadway, to the Edison Building, 42 and 44 Broad street, Rooms 1, 2 and 3, fifth floor.

Curtis & Dean, the agents of the Thomson-Houston Electric Co., have removed from 115 Broadway to 38 and 40 New street.

The Storage Battery Supply Co. have removed to the northeast corner of Twenty-third street and First avenue.

The New York Insulated Wire Company, of 13–17 Cortlandt street, have issued a very neat and comprehensive illustrated pamphlet devoted to their "Vulca" duct. It gives a variety of details as to those tubes for interior wiring, with engravings, prices, etc., and has also an excellent section on electric light wiring installations and the features of safety and permanence that have to be taken into account.

NEW ENGLAND NOTES.

The Electric Gas Lighting Company, of Boston, have just issued to the electrical trade, a circular calling attention to the fact that an Indiana house has recently put on the market a new battery which they call the "Hercules" and which they claim is identical with the Samson with "certain improvements." The circular denounces in no measured terms the action of this company, which they claim is wholly piratical, and then goes on to give the results of two sets of comparative tests of the Samson and the new Hercules, one made by Prof. Dolbear, of Tuffts College, and the other by Prof. C. F. Brackett, of the Department of Electrical Engineering at the College of New Jersey, Princeton, N. J. These tests have evidently been made with the utmost care. Prof. Dolbear in concluding his report says: "From all this I conclude that for sustained service, recovery after service, and electrical output, the Samson cell is superior to the Hercules; indeed, I know of no ammonium chloride cell that approaches the Samson in desirable qualities." Prof. Brackett winds up his report with the following words: "It appears from the foregoing details that the 'Samson' cell is in every way greatly superior to the 'Hercules.' It has much less internal resistance, a much greater sustaining power as respects voltage, consequently it affords a much greater current, and this through a very much longer time; and lastly, its power of recovery is very much greater. Indeed, I know of no open-circuit battery cell which can compare with it." All interested in battery work should procure a copy of their circular, as they will find much therein that is interesting and instructive.

The Bradbury-Stone Storage Battery Company, of Lowell, Mass., have just issued a very comprehensive and interesting catalogue relating to storage batteries, and their varied uses for electric light and power. In this catalogue they make strong claims for its practicability in street railway work, and give some interesting examples of its success in this line. Its adaptability is also clearly set forth for use in mill tramway service, mining service, propulsion of vehicles, propulsion of launches, elevators, cash carriers, dental lathes and drills, church organs, phonographs, fans, coffee mills, deposition of metals, various kinds of electric lighting, and a host of other services too many to enumerate. The book is well illustrated and shows the battery in various forms, and contains useful tables for calculating the size of battery required. There are also a number of illustrations of special switches and various devices used in conjunction with the storage battery, and the book concludes with a large number of the warmest kind of testimonials from many who have used the battery with the most gratifying success.

The Electric Heat Alarm Company, of Boston, are in receipt of two very warm testimonials regarding the working of their heat alarm apparatus, from the Paine Furniture Company, and E. B. Stillings & Co., both of Boston. These installations have been working now for some weeks, have done all that was claimed for them, and have already warned the attendant engineers of bearings which were growing too warm for safe working. All engineers should investigate this system closely, as it is easily and cheaply applied, and affords a protection which it is difficult otherwise to get.

The Fitchburg Engine Company, of Fitchburg, Mass., have moved into their new and capacious factory on the outskirts of Fitchburg, and have now got much more ample room for the speedy execution of their numerous orders. They have erected a handsome two-story brick building, 100 feet long by 75 feet wide, and have fitted it up with the most modern machinery. Overhead travelling cranes traverse the entire shop, and shipments are made direct on to cars on a side track of the Fitchburg Railway, specially run in for the purpose.

Thf Massachusetts Electrical Engineering Company, of Boston, have been appointed by the State House Commissioners to take entire charge of the installation of the electric light plant for the new Boston State House extension, and are at present preparing plans and specifications for this work. No contracts have yet been awarded, but they will be given out as soon as the plans are completed.

Mr. Hollis French has become connected with the Massachusetts Electrical Engineering Company, as one of their regular staff of electrical engineers. Mr. French, who is well known in electrical circles, has been abroad for the past year on electrical business, and brings with him a wide experience in all kinds of electrical engineering work, gathered in this country and abroad.

The Corliss Steam Engine Company, of Providence, R. I., have just completed the installation of another, the third, engine in the central station of the Worcester Electric Light Company, of Worcester, Mass. This engine will be of their regular Corliss type, with cylinders 22 inches and 42 inches by 48 inch stroke. The fly-wheel is 22 feet in diameter, 62 feet face and weighs 55,000 pounds. The engine at 79 revolutions, will develop about 600 h. p., and has been built extra strong all through, being a magnificent specimen of the Corliss type of engine for electrical purposes.

The Porter and Leavitt Manufacturing Company, of Providence, R. I., have now got comfortably settled in their new quarters on Mitchell street, and have now ample capacity for transacting their largely increasing business in fan motors. The Porter and Leavitt motor has made quite a reputation for itself in the past year, and business prospects for the coming year are extremely good, a good reliable small motor, capable of being run from batteries, being highly appreciated.

WESTERN NOTES.

The Blake Pump.—No single piece of machinery in an electric light or power plant is more sensitive than the boiler feeder. It is therefore of high importance that the pumps used for this purpose be of the highest excellence. The Pond Engineering Co., report great success with their Blake pump for this service. Recent shipments going to Albia, Ia., Electric Light Co.; Holden, Mo., Electric Light Co.; Warrenton, Mo., Electric Light Co. Janesville, Wis., Electric Street Railway Co.; Camden, Ark., Electric Light and Power Co., two; and Cicero and Proviso Street Railway, Chicago; Vincennes, Ind., Electric Light & Power Co., two.

The Central Electric Company have just secured the Western agency for Schoenberg's pneumatic annunciator reset. This is a very valuable and unique device for replacing the drops in annunciators, which is done by simply pressing a rubber bulb which drives air into a rubber bulb at the other end which raises the drop as it expands. It has been illustrated in **The Electrical Engineer**.

The Electric Appliance Company report that spring business is beginning to make itself felt. The sales of Paranite wire are increasing in a manner that gives evidence, they say, that it has not failed to meet the highest requirements. The demand for "Canvas Jacket" wire also indicates that the general tendency is for a higher grade of line construction.

Mr. Gilbert G. McDuff, well known as a newspaper man in electrical circles in the West, has accepted a position with *The Electrical World*, and will represent that concern on electrical directory work throughout the country.

The Railway Equipment Co. report business as very brisk, and already have several large contracts for line material and equipment for new street railway plants and extensions.

Mr. P. C. Burns, of the Peru Porcelain Works, was in Chicago visiting last week and has taken his usual orders for porcelain specialties they manufacture.

Mr. W. L. Moase, of the Detroit Electrical Works, was in Chicago last week. He reports an excellent trade throughout the West and Northwest.

Charles E. Wilson has accepted a position as salesman with the Railway Equipment Co.

PHILADELPHIA NOTES.

Partrick & Carter Co. have discontinued their Canadian agency, and will hereafter supply the trade direct from their Philadelphia headquarters, 125 South Second street. They will send catalogues and special trade discount sheets to any Canadian or other address upon application.

Mr. Chas. E. White, who for the past two years has acted as superintendent of the Pottstown, Pa., Electric Light Co., has resigned his position there to occupy a similar one with the Front Street Merchants' Electric Light Co. of this city.

Prof. L. F. Rondinella, M. E., mechanical, electrical and civil engineer, has opened new offices at 705 Chestnut street, Philadelphia. He will continue his work, however, at the Central Manual Training School.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

Electrical Engineer.
VOL. XIII. MAY 11, 1892. No. 210.

LONG-DISTANCE TELEPHONY.—II.

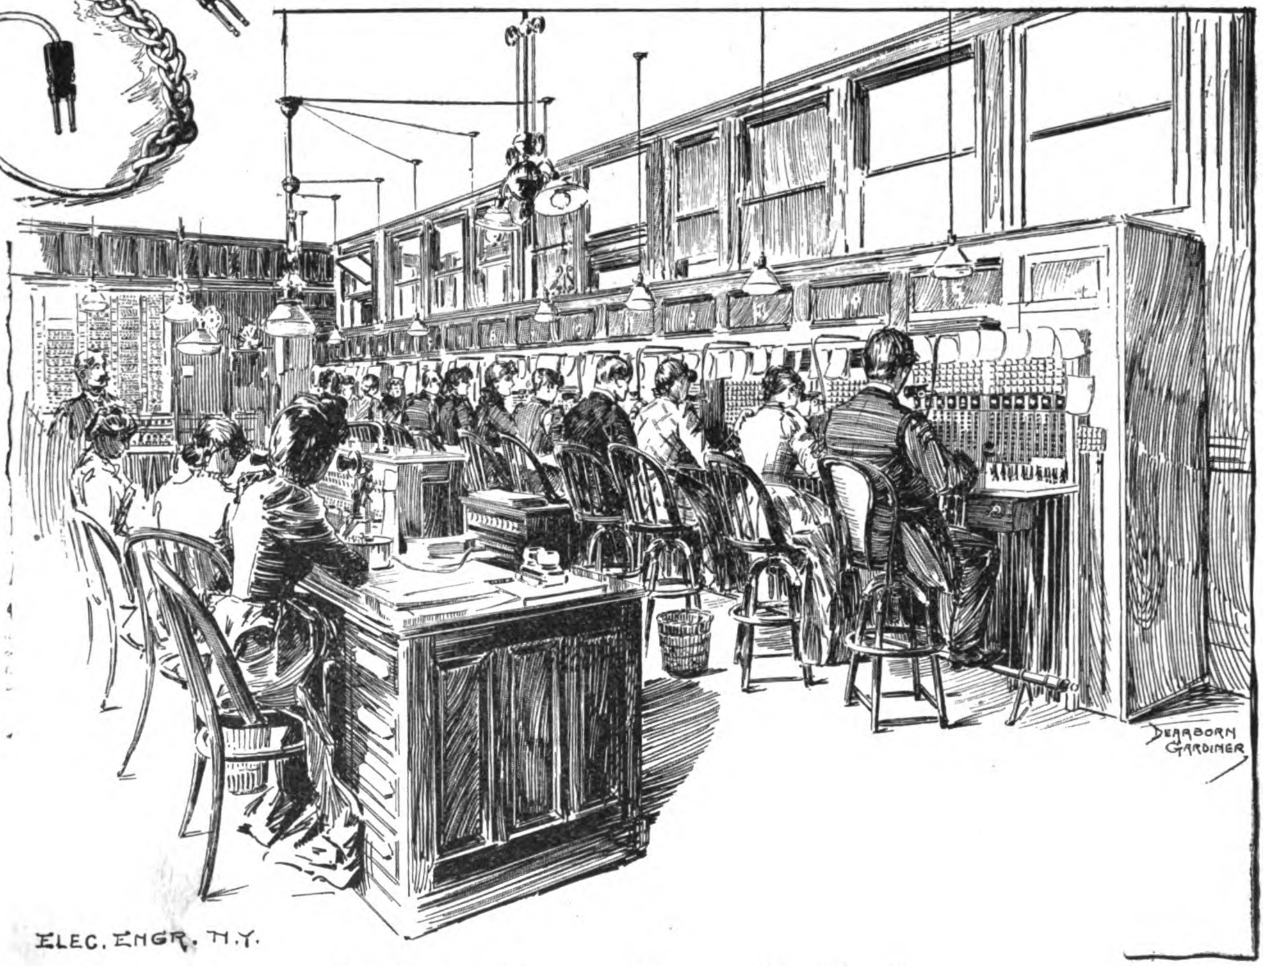
BY

Herbert Laws Webb

IX.

O FAR we have chiefly discussed the part that the line plays in the long-distance telephone system and it has been made plain how important a part that is, but although it is true that a great deal of attention and study has been devoted to the line question, the other elements of the circuit, such as transmitters, receivers, annunciator drops, switching apparatus, bells, repeating coils, lightning arresters and all the various items of office and terminal equipment have by no means been neglected. Both in the laboratory of the American Bell Telephone Company, at Boston, and in the engineer's department of the American Telephone and Telegraph Company, at New York, skilled experts are constantly at work devising new instruments and working out modifications and improvements on old ones. Every portion of every instrument undergoes expert inspection and criticism and the dimensions and style of every screw, washer and binding post are set forth in the specifications drawn up for the manufacture of all the various pieces of apparatus that are used.

The instrument equipment of a long-distance line differs materially in various particulars from that of a local telephone line. A more powerful transmitter—one capable of a greater range of variation of resistance and of employing a stronger battery current—was the first desideratum, as the high resistance in such long lines required all that could be obtained in the way of what we may call sound energy to allow for loss in transmission. The ordinary type of Bell receiver is such a delicate instrument that it leaves no room for further refinement in this direction; the improvements that have been made in it have been mainly mechanical rather than electrical, and it remains what it was when first given to the world—the most wonderful and the most delicate instrument known to electrical science.



LONG-DISTANCE TELEPHONE EXCHANGE, NEW YORK CITY.

The transmitter adopted by the Long-Distance Company is a modification of the Hunning instrument, employing granular carbon as the medium for varying the resistance in the battery circuit. The original long-distance transmitter was devised at the laboratory of the American

Bell Telephone Company; its design is totally different from the original Hunning instrument, the only similarity being in the use of granulated carbon which Hunning adopted instead of two solid electrodes in light contact with each other. It is an extremely compact instrument, needs no adjustment after once set up (providing that it is not ill-treated) and has given excellent service during the years that it has been in use. It is now being replaced by a later form of instrument constructed on the same principles but after a different pattern; this new transmitter, called the "solid back," even excels the familiar "long-distance" as an efficient transformer of sound waves into electric undulations.

The long-distance transmitter consists of a little circular metal chamber which is generally attached to a hinged arm mounted on the iron box that contains the induction coil. To the neck at the lower part of the metallic chamber is fixed a hard-rubber mouthpiece which directs the voice to the platinum diaphragm that rests on an insulating ring placed at the bottom of the chamber. This platinum diaphragm is clamped down by a brass ring; and a binding post, insulated from the chamber, which passes through it near the edge, affords a connection for one side of the battery circuit. Above the brass ring is placed a collar of boxwood, which forms a small insulated receptacle for the granular carbon. A brass electrode, shaped like a pulley wheel and having radial holes, fits loosely into the insulated chamber; the upper flange of this little pulley rests on the rim of the metal chamber, making good contact with it, and the lower surface, which is slightly concave, comes within about a sixteenth of an inch of the platinum foil diaphragm. The granulated carbon, which is so finely divided as to be a fine flaky powder, occupies the spaces between the electrode and the diaphragm and between the grooved periphery of the electrode and the insulating collar; the radial holes in the electrode serve the purpose of exposing additional surface to the granulated carbon. As the electrode is in close contact with the transmitter chamber, the primary circuit is completed through the chamber and the supporting arm to the thick winding of the induction coil. This transmitter has been the result of a vast deal of study and experimenting, and while being extremely compact it is very little liable to get out of order or to fail from any cause except bad usage. The platinum foil diaphragm, being the most vulnerable portion of the instrument, is protected from the attacks of inquisitive lead pencils or other implements of unskilled labor by the insertion of a couple of wires across the narrow part of the mouthpiece—a very necessary precaution.

X.

The latest type of long-distance transmitter is called the "solid back" because the chamber containing the electrode and diaphragm is mounted vertically in front of a solid metal backing in place of the horizontal chamber and adjustable arm of the instrument just described. In the "solid back" the brass electrode is done away with and an extremely small metal chamber is employed. To the diaphragm is attached a small button of hard close-grained carbon prepared by a special process for this purpose. This granular carbon button serves as one electrode and presses lightly against a thin layer of granulated carbon, which it thus holds in position in the little metal chamber that forms the second electrode. This arrangement is compactness itself and the mechanical design of the instrument is very good. No adjustment whatever is required when once the transmitter has been put together and properly tested. The electrical efficiency, as has already been stated, is even greater than that of the original long-distance transmitter.

Both these transmitters are worked with a primary battery current having an electromotive force of about six volts. The electromotive force should not fall below this figure and the internal resistance of the battery should be as low as possible, to give the best results. The resistance of the primary winding of the induction coil used with the long-distance transmitters is .4 ohm and as the lowest resistance of the transmitter itself is only a few ohms the total resistance in the primary circuit is very low; a battery that will not polarize quickly is required for the work, especially as the instruments are often used for long periods without a rest. The Fuller bichromate battery has been found to give the best results, and three cells are supplied with a long-distance outfit. This amount of battery gives the requisite electromotive force of six volts, and when in good condition the cells have a fairly low internal resistance. The current taken by the long-distance transmitter when the battery is in good condition ranges from .6 to .7 of an ampere; if the current were to exceed the higher figure by very much the transmitter would become too hot and its speaking efficiency would be lowered. The resistance of the secondary winding of the induction coil is 14 ohms; the coil is wound over an extra long core and is enclosed in an iron box to which the transmitter arm is attached.

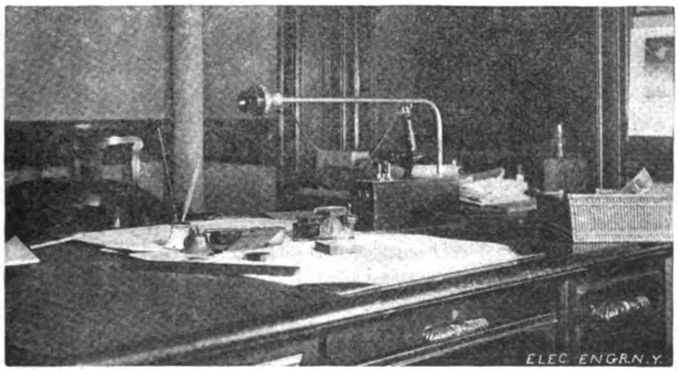
XI.

The long-distance instruments are most familiar to the general public in the form of cabinet sets, an extremely sightly form of telephone instrument. The transmitter arm is mounted on a neat little desk, which is provided below with a small closet for the batteries. In an enclosed compartment at the back of the desk are fitted the induction coil, magneto bell and generator, automatic switch and lightning arresters. Where space is an important consideration, wall sets are supplied, the various parts of the equipment being mounted on a more or less ornamental backboard, which is fixed to the wall in the same manner as an ordinary Blake set. The long-distance transmitters, being of compact form and ornamental finish, are well adapted for combination with neat metal stands for desk use. Of these desk instruments quite a variety of patterns has been designed by the telephone companies, principally for use in their own offices, where telephone communication between the different departments and out-of-town offices is in constant requisition. With these desk instruments it is of course necessary to provide special switching and bell equipments and a separate place for the battery, as the desk stand only carries the transmitter and receiver.

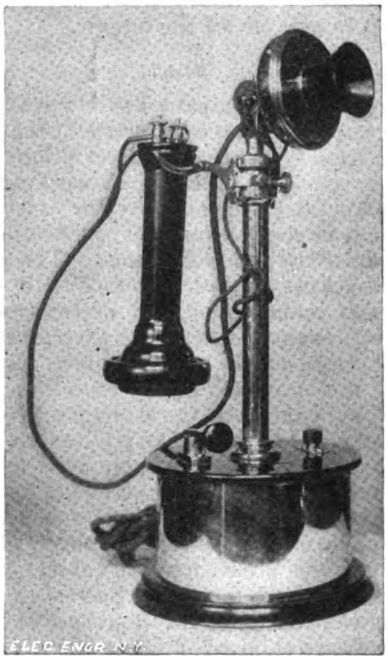
The utmost care is always taken in keeping the long-distance instruments up to the top notch of efficiency. Practically the only part of the instrument equipment that really requires taking care of and attention for maintenance is the battery, as all the working parts are of such good material and so carefully put together and protected that it is very seldom that anything goes wrong with them. It is highly necessary, however, that the battery shall be maintained in the very best order as a very slight falling off in its strength makes a considerable difference in the efficiency of the transmitter, much as a slight decrease of pressure in an incandescent circuit causes an altogether disproportionate loss of illuminating power in the lamps. A very simple and effective test of the strength of the transmitter was accidentally hit upon some time ago by the general superintendent and the engineer of the Long-Distance Company during the course of some experiments that they were making on a line. In order to muffle the sounds coming over one circuit, on which one of the experimenters was talking in a loud tone, to obtain quiet for listening for induction on the other, the turbulent receiver was held against the mouthpiece of the transmitter of its own circuit. The receiver immediately gave out a loud musical note of high pitch, which was sustained as long as the receiver was held in front of the transmitter. The explanation of the phenomenon is simple enough. The diaphragm of the receiver being in a state of vibration acted through the column of air separating the two, on the diaphragm of the transmitter, which in turn reacted through the induction coil on the receiver, the impulses following each other with sufficient rapidity to form a musical note. It was found afterward that the note could be produced by giving the receiver a slight tap against the transmitter mouthpiece, or by calling or whistling into them when held together so as to start the vibration. This automatic performance of the telephone was experimented with to a considerable extent just after the discovery was made, and at times a perfect chorus of shrill shrieks could be heard on the second floor of the Telephone Building, which is chiefly occupied by the technical departments of the Metropolitan and Long-Distance companies. A favorite diversion with the experimenters was to call somebody up in another office and ask him to listen for a moment, then to place receiver and transmitter together and start the note, which of course was produced with equal distinctness in the distant receiver. As a result of these experiments it was found that the note could only be obtained when the battery was in very good condition; if the battery was at all run down all efforts to start the note would prove unavailing. Consequently the effect was applied to a useful purpose and has since served as an acoustic battery test; if the telephone will sing it is taken as a sign that the battery is up to the mark, whereas silence means just the opposite. It has been found, however, that this battery test is not so reliable as was first thought, because a decided change is produced in the note when the connections either of the battery or of the receiver are reversed. Generally, if the battery is strong, the telephone will sing either way, but a reversal of the battery or of the terminals of the receiver will raise or lower the pitch of the note. The consequence is that on occasions the battery may be just strong enough to make the telephone sing when the connections are in one direction, but if the connections are reversed the telephone will remain silent in spite of all efforts to start the note. As a battery test, then, the note can only be taken as an approximate indication of the state of affairs.

XII.

In the operation of long-distance telephone lines it was soon found that the ordinary methods of connecting instruments and switchboard apparatus in series would have to be modified and that the two sides of the metallic circuit must be made as much alike as possible. A great many experiments were tried before the fundamental result was arrived at that in order to eliminate all disturbances and secure a perfectly quiet line it was necessary that the two sides of the circuit should balance exactly in all respects—copper and insulation resistance and inductive capacity. If there were sufficient variation between the resistance or capacity of the two sides of the circuit to seriously upset the balance, inductive disturbances would be introduced, and if the insulation of one of the wires were good and that of the other very low, a similar effect would result. So easily may the balance be upset that a long line, which under ordinary circumstances is perfectly quiet, may be rendered extremely noisy, so much so that it is almost impossible to talk over it, by the addition of a very slight resistance or capacity to either side of the circuit. In the case of the London-Paris telephone line it has been stated that by connecting a condenser of only a fraction of a microfarad capacity to one side of the circuit the balance was entirely destroyed, although the line is normally absolutely inductionless. The refined methods of line construction previously described provide for the line itself being properly balanced, and the balance is preserved at all points where instruments are connected to the line by bridging them across instead of looping them in direct according to the old system. The annunciator drops on the switchboards are bridged, and where several instruments are connected on one line they are all connected in bridge; the operator's circuit at the exchange is also joined in bridge so that all the apparatus on a long-distance telephone line is connected in multiple arc, just as in an incandescent electric light system. In this manner a practically perfectly balanced line can be secured, but in order to secure efficient working on this plan it was necessary to considerably modify the types of apparatus previously in use on the looping-in system.



LONG-DISTANCE TELEPHONE SET FOR DOUBLE DESKS.



LONG-DISTANCE TELEPHONE SET.—UPRIGHT PATTERN.

In order to bridge instruments across the line at different points it is necessary, of course, that the distribution of the current should be borne in mind and that the bridges should be of sufficiently high resistance not to short-circuit the line at any point and thereby prevent good transmission between the stations beyond. The peculiarities of the telephonic current and of the alternating current used for ringing purposes have to be taken into account in designing apparatus to be connected in multiple arc, and the phenomenon of retardation comes in very usefully in this respect. By constructing coils of such dimensions as to take proper advantage of the effect of retardation, annunciator drops or bell magnets may be permanently bridged across the circuit without in the least impairing the efficiency of transmission, even on very long lines. The coils are wound with very fine wire to an extremely high resistance, and the high coefficient of self induction of the coils results in enormous impedance to alternating currents so that the bridge absorbs but a very minute proportion of the speaking current. The automatic bridging magneto bell designed by Mr. J. J. Carty operates on this principle. The ringer magnets are permanently connected in bridge across the line, and with a line containing as many as twenty or thirty stations the transmission between any two of the stations is practically as good as if no bells at all were in circuit. The experiment has been tried of connecting a large number of the bridging bells in circuit with a long-distance line between New York and Boston, and no difference could be noticed in the transmission when the bells were cut in and out of the circuit.

XIII.

The Long-Distance Company has always devoted great attention to the perfection of all parts of the equipment of its lines, and from the foregoing description of the exigencies of long-distance metallic circuit-working it is obvious that there is abundant opportunity for scientific research and experiment in connection with the complicated apparatus that modern telephony demands. The improvements that have been made in the various details of the equipment are almost innumerable, and experience and experiment constantly suggest others. A great deal of study has been concentrated on the central office question, which, while it does not approach in the magnitude of its problems that which confronts the managers of local systems in large cities, still has many fine points that are rendered none the less easy because the same care and refinement must be maintained in the mazes of switchboards and office connections jammed into a small space as are observed on poles and cross-arms, where there is plenty of elbow-room, and in the luxurious dimensions of cabinet sets, where no two wires are allowed to cross. Special metallic circuit switchboards were designed for the long-distance operating rooms. These switchboards are not wired on the multiple system, as the nature of the connections and the number of circuits in use do not render the use of multiple switchboards advantageous. The circuits in the switchboard, instead of being each connected to one spring jack, are separated, and the two sides of a metallic circuit are connected to two separate spring jacks. This arrangement was made in order to avoid all risk of leakage and other troubles in the spring jacks. A special twin plug, made by placing two ordinary round plugs in a single handle, is used to make contact with the two spring jacks, which are placed close together, but thoroughly insulated from each other, in the switchboard. The annunciator drops used on these switchboards are known as the "tubular" drops, and were designed for long-distance working; they have high retardation and are connected in bridge across the circuit. Special metallic circuit ringing keys are provided, by means of which the operators can throw the generator current on to any line by merely pressing two small buttons; the generators are kept running constantly by means of an electric motor and leads from the generators are run through the switchboard and tapped to the ringing keys. The listening keys by which the operator's outfit of transmitter and receiver is bridged across the line are of the cam lever pattern, extremely easy to manipulate. The working parts of the ringing and listening keys are protected from dust beneath the shelf of the switchboard, only the buttons and cams showing above. The keys make contact by pressing down thick wedges of hard rubber between two sets of metal springs. Normally the wedge is up and the springs are insulated from each other; when the wedge is pressed down the springs are pushed together and make contact. The contacts are always kept clean, as the springs are so designed that there is a slight rubbing action when they are brought together and separated.

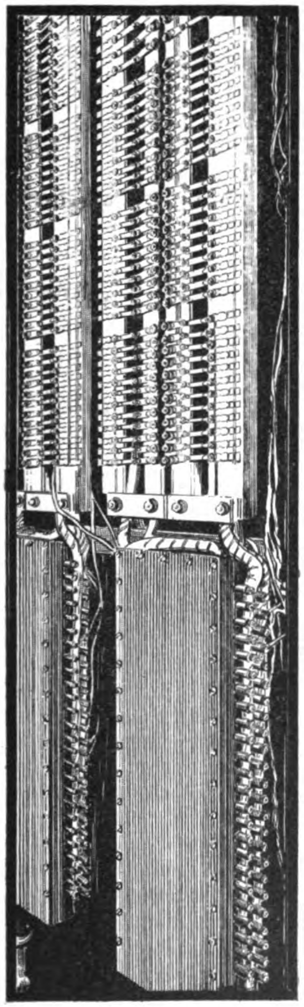
The protection of their lines and apparatus from damage by lightning and strong currents from other electrical systems is a question to which telephone engineers have devoted unceasing study. There are various points in an extensive telephone plant that require protection, and different measures have to be adopted in different situations, thus materially complicating the problem. A long telephone line is generally made up of overhead wire with occasional links of submarine cable at river crossings and a few miles of underground cable at the city terminals of the line. The submarine cables must be carefully protected as they are expensive and take time to replace or repair if damaged; the underground cables need efficient protection for the same reasons. The delicate apparatus at the subscribers' stations and at the exchange calls for the most jealous protection because a "sneak current" of very moderate strength will soon store up sufficient heat in the fine windings of bell magnets and annunciator coils to burn them out. At places which are not readily accessible, such as cable houses at river crossings in the country and cable towers on poles at the outskirts of towns, the protecting apparatus must not be so delicate as to interrupt the circuit unnecessarily, but must be gauged to act just at the point when the portion of the circuit which it guards is in danger, and no sooner. For the proper protection of insulated metallic circuits some device is required which will act when the line is charged to a high potential by accidental contact with a high tension circuit. It might easily happen that a wire belonging to an electric light or power line operated at high voltage should come in contact with a well-insulated metallic circuit telephone line, in which case the telephone circuit would become charged to the potential of the foreign wire and there would be no flow of current to operate a fuse or other style of arrester dependent on current for its proper action. It is necessary then to provide for this possible condition, which, of course, might render the circuit dangerous in several senses. Lastly, arresters or protectors containing electromagnets to be inserted in the line are not looked on with favor by telephone men owing to the retardation introduced by the electromagnets, which naturally militates against good transmission. From all this it will be seen that the proper protection of metallic circuit telephone lines and apparatus from damage by foreign currents is no very simple undertaking.

XIV.

The telephone companies by dint of careful experimenting have worked out a thorough system of protection for all points open to attack. At submarine cable crossings a special form of brass plate air space lighting arrester is inserted between the line wire and the cable. A spiral coil of copper wire is also placed in circuit; the impedance offered by the coil to a sudden rush of current induces the discharge to jump the air space to ground rather than to enter the cable. This arrester is also provided with a fuse which melts and opens the circuit when the current flowing reaches ten amperes; this fuse protects the cable from damage by a steady current which might be sent through the overhead wire through accidental contact with an electric light or power line. At the junction between an overhead line and an underground cable a fuse which blows at eight amperes is inserted in the circuit for the protection of the cable conductors. It was formerly the practice to place more delicate fuses, designed to blow out at, say, two or three amperes, at the outer terminals of underground cables, but so much delay was caused by the fuses blowing out and opening the line on the slightest pretext that it was decided to let the cable take care of anything up to eight amperes, which it can safely do, and to look out for small currents at the office end, where burnt-out arresters can be more easily and quickly replaced than they can be on cable poles in the suburbs. At the exchange terminals of the underground cables a special form of strong current and lightning arrester, designed at the laboratory of the American Bell Telephone Company, is connected to every conductor. This arrester is provided with an air space cut-out which interrupts the circuit and grounds the line when the circuit becomes charged to a potential of 300 volts. The line being grounded, current will flow, and the fuse at the outer terminal will open the line and prevent any damage to the cable conductors. A "sneak" current arrester completes the protection afforded to the instruments; this consists of a small coil of fine wire wound on a little bobbin through which a metal pin passes but is prevented from passing clear through by a drop of fusible metal. A current of .28 ampere circulating in this coil for thirty seconds generates heat enough to melt the fusible metal, releasing the metal pin and the spring which it holds down. This spring grounds the line, and all the apparatus beyond the arrester is cut out of circuit. Subscribers' instruments are provided with lightning and strong current arresters of the same pattern as those used in the central office. No current of sufficient strength to injure the instruments can possibly pass these delicate arresters.

XV.

Long-distance operating-rooms are established in all the principal cities to which the system extends; they are generally in intimate connection with the principal local exchange, as of course many patrons of the long-distance service are among the subscribers to the local service. The New York office is in the Telephone Building at 18 Cortlandt street, and is immediately below the largest exchange of the Metropolitan Telephone and Telegraph Company. A description of this office will serve as a typical illustration of the manner in which the long-distance service is conducted. The wires are brought into the exchange through underground cables, which reach the overhead lines at various points by means of the underground system of the Metropolitan Company. These cables are headed up immediately outside the operating-room and connected to a small cross-connecting board, at the opposite side of which are terminated the wires from the switchboard. The cross-connecting board is an iron framework divided into vertical and horizontal runs through which the wires are led in definite courses. The line wires being all soldered to rows of metal plates mounted on hard-rubber strips at one side of the board, and the switchboard circuits being terminated in the same manner at the other, any pair of line wires can be connected to any switchboard circuit by running a pair of wires through the cross-connecting board. This arrangement forms a very convenient method of making new connections or effecting changes in existing ones, as all the work required is done with a single pair of wires run between two fixed points. Between the cross-connecting board and the switchboard proper all the wires pass through a test board, where every wire is connected to a spring jack; of these test boards there are two, one for wires leading east from New York and the other for wires going west.



Cable Terminals on Cross-Connecting Board.

The test boards are provided with Morse keys and relays, Wheatstone bridge and galvanometer for testing the lines. Every morning at an early hour a test is made on every line by the chief operator, who enters the results in his log book. When the lines are all in good condition the testing does not occupy very long, and, as we have already seen, it frequently happens that no trouble is found on any of the lines. When a trouble is discovered, its locality is traced down very quickly; different stations are cut in on the defective circuit until the trouble is placed between two of them, and then, if the lines are crossed, copper resistance measurement will give the location of the cross with very fair accuracy. Regular testing stations are established at fixed intervals along all the main lines and competent linemen are in readiness at various points to start out to remove troubles and make repairs at a moment's notice. So systematically is the daily testing of the lines done and so quickly are ordinary troubles traced out and attended to that it is very seldom that any line remains out of service after ten o'clock in the morning, the daily tests being made between the hours of seven and eight a. m. Every trouble discovered is noted in the log book of the chief operator together with all details as to its nature, location, the name of the lineman sent to repair it, the time he started and where from, and so on. The next entry will be the time the circuit was made O. K. again, together with any further remarks relating to the report made by the lineman. All these records are carefully preserved and tabulated, and if it is found that troubles frequently occur in a certain locality or on a certain circuit a definite cause is suspected and a strict inquiry is made in order to strike, if possible, at the root of the evil. In this manner much curious and useful information is obtained as to the conditions which affect the working of overhead electric wires in various parts of the country. Of course, during severe storms the wires and poles must necessarily suffer to some extent and there are occasional extraordinary combinations of atmospheric disturbance which the weather students account for by wonderful stories about a cold wave from the northwest meeting a warm wave from the southwest and the two mixing themselves up with a hurricane from Tennessee and an Atlantic gale charged with vapor from the Gulf Stream; against such phenomenal meteorological vagaries as these, which are commonly called blizzards, the stoutest construction cannot always hold out at every point. But when accidents happen the long-distance company is not content to rebuild merely and be done with it; a detailed investigation is made and the lesson is profited by to the fullest extent. If the experience suggests improvements they are adopted, and if weak spots are discovered they are carefully avoided in future work, so that a certain amount of valuable information may be extracted even from a destructive blizzard.

Desk Telephone Set.

XVI.

From the test board the lines run to the switchboards where they are connected to twin spring jacks and bridged tubular drops, as previously described. The switchboards are divided up into different sections at which the lines are terminated according to the districts which they reach; for instance, one section contains the lines running to New Haven and Hartford, another those going to Bridgeport, Norwalk and Stamford, another Boston, another Philadelphia, and so on. This arrangement of switchboards is found to suit the nature of the business very well and no substantial departure has been made from it since the operating-room was first equipped—about four years ago.

At the same switchboard a number of local lines are terminated on special drops; these lines are rented by business men and firms in New York, who use the long-distance service to a large extent, many of them requiring connection with certain points for several hours each day. The local lines terminated at this board are those of subscribers the greater proportion of whose business is with the same outside places; the lines are therefore distributed through the switchboard in proximity to the trunk wires with which they most frequently have to be connected. In another part of the operating-room is placed a smaller switchboard, connected by trunk wires to the various sections of the principal board; here a number of local lines are terminated the renters of which require communication with various points in the long-distance system. Their connections are more easily handled through this intermediate switchboard than if the lines were terminated at the main board; the operators who handle these local wires are connected by trunks to every section of the main switchboard and they pass on the connections by these trunks, giving the trunk wire operator the order for the connection required over a calling circuit. At the extreme end of the operating-room is placed a section of the metallic circuit multiple switchboard of the Cortlandt Street Exchange of the Metropolitan Company. Nearly 5,000 lines of New York subscribers terminate at this switchboard and the placing of a complete section in the long-distance operating-room greatly facilitates the work of making connections between local subscribers and long-distance points or subscribers in any of the cities reached by the long-distance system. Trunk wires are run from the local multiple section to the various sections of the long-distance switchboard and two operators are kept constantly busy making long-distance connections for local subscribers. The section of the multiple switchboard is provided with special four-point spring jacks by means of which the circuit running through the rest of the board is cut off when a long-distance connection is put up, thus preventing an operator at any of the other sections from cutting in on the line and obviating the risk of any accidental interference with the conversation. A further improvement is to throw on a special test current in addition to cutting off the multiple switchboard circuit so that the line if tested by the operators at the other sections shall show busy in the long-distance room. Trunk lines run from the long-distance switchboard to the other local exchanges in New York, so that long-distance connections with local subscribers can be made with the minimum number of switchboard connections.

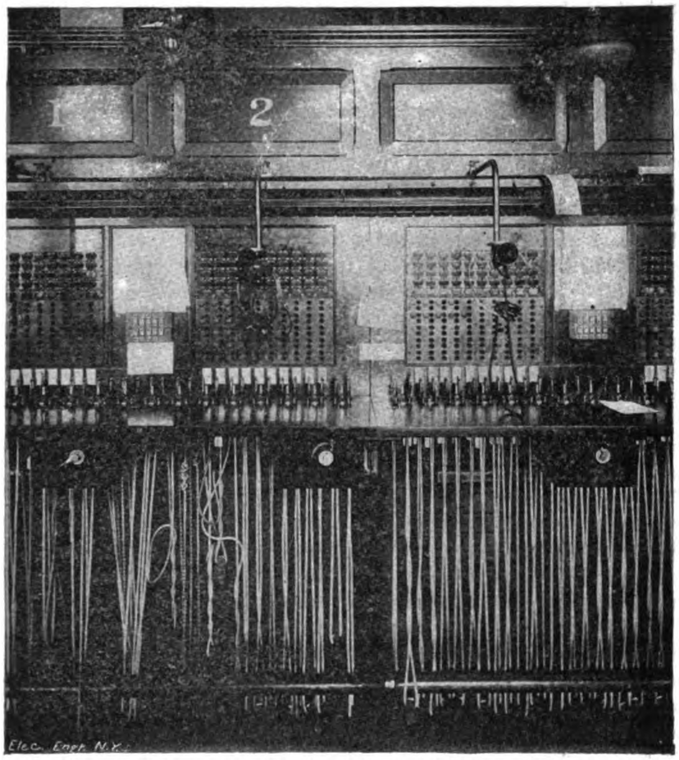
XVII.

The operators are provided with adjustable long-distance transmitters and head receivers of the regular type used in all exchanges. On the shelf below the spring jacks and drops are placed the plugs and cords for putting up connections, the terminals of the trunk lines which join the different sections and switchboards and the operators' listening and ringing keys. Every connection made is entered on a blank at each end of the line; the entry on this blank states the places between which the connection is made, the names of the speakers, the time at which the connection is put up and taken down and the number of the circuit used; the check is signed by the operator and she is responsible for the accuracy of the entries.

The operation of the long-distance service is sufficiently complicated and varied, but the work is so thoroughly systematized and so carefully supervised that very little time is lost in making connections and in taking them down when the line is finished with. A large proportion of the connections are calls for short conversations from local subscribers and from the pay stations established in all parts of New York and other large cities. The principal pay station is that which occupies the first floor of the Telephone Building, at 18 Cortlandt street; it contains six booths, which are in constant requisition all day long. All the pay stations where much business is done are supplied with sound-proof booths, which greatly add to the comfort of a talk over the telephone. Most of the business done by the pay stations and the chance calls of subscribers to the local system is in the form of five-minute conversations, five minutes being the minimum time charged for. In order to work the wires to their best capacity it is obvious that the necessary switching and ringing on the part of the operators must be done very smartly and smoothly, because several minutes, say two or three, may easily be spent in putting each connection through and in restoring everything to its normal condition when the conversation is finished. Although a certain amount of time must obviously be allowed for making the connections called for and for discontinuing them at the end of the specified time, yet it is equally obvious that the time during which the plant and staff are unprofitably engaged must be reduced to the lowest possible fraction of the working day. At first sight one would say that at five minutes for a talk each circuit would accommodate 12 conversations in an hour. But allowing about three minutes for switching and calling at both ends of the line and taking down the connection afterward, we get about seven or eight talks in the hour and find that for about 40 per cent. of the time the plant is earning no money.

By way of reducing this percentage the principal main lines are now worked on the double-track system, all connections being ordered up and down over a special calling circuit. The rapid increase of busines has rendered necessary the adoption of this system, which results in a large saving of time. Between New York and Boston, for instance, a certain number of circuits are set aside for work originating in Boston and a certain number for work originating in New York. One pair of wires between New York and Boston is used exclusively as a calling circuit to transmit orders for putting up and taking down connections. At each office the lines terminate at two sections of the switchboard, one for inward service and the other for outward; the operator at the outward board speaks directly to the operator at the inward board at the distant office over the calling circuit, which terminates at the inward operator's head telephone. The sending operator at New York gets a call from Williams & Robinson for communication with John Brown & Co., of Boston. She plugs them on to a line and calls to the Boston operator "John Brown & Co. on 15 and 16 for Williams & Robinson." The Boston operator plugs John Brown & Co. on to circuit 15 and 16 and the connection is made. When the New York operator gets the clearing-out signal, or when the time is up, she tells the Boston operator to take down 15 and 16 and the line is clear again. The same performance takes place with the other set of lines, the only difference being that Boston does the ordering up and down. This system does away with all the work of ringing up, waiting for clearing-out signals at both ends of the line and other minor causes of delay, and the saving of time and consequent improvement of the service amply compensate for the withdrawal of a circuit from public use to be used exclusively for the regulation of the traffic.

Besides the pay station business and that arising from calls by local subscribers the long-distance system has a great many regular patrons who use the service every day. Others transact so much of their business by telephone that they require the exclusive use of a long-distance line for several hours each day, the time being generally divided up so as to give two or three long talks during the day. Others, again, rent the entire use of a line and maintain communication between their different establishments throughout the day. Besides all this private business, the long-distance service is in high favor with railway corporations and newspapers. For the transmission of orders relating to the operation of railways the telephone has the advantage of being a time saver, as talking is far quicker than telegraphing; another good point that endears it to railway managers is that the long-distance wires remain in working order at times when the telegraph lines are completely paralyzed. The Pennsylvania, New York Central, Old Colony, and Boston and Albany railway companies make extensive use of the telephone for the transaction of their business, and on various occasions have had to rely on it completely for days at a time. The newspapers also have sometimes had to depend exclusively on the long-distance telephone for out-of-town news, as, for instance, after the blizzard of four years ago; having once used it they have been quick to see its adaptability to many of their special needs. For reporting races, baseball and football games, elections and other occurrences in which a lively public interest is taken from the field of operations the telephone is infinitely superior to the telegraph. Some time ago a New York daily paper sent a reporter to Boston to describe a baseball game of special importance. Instead of adopting the usual method of taking notes to be sent by telegraph, a long-distance circuit was arranged for connecting the baseball grounds directly with the head office in New York. The reporter was provided with a telephone outfit and he simply had to describe the game as it went on, his dictation being handed to the compositors as rapidly as it was received. Three minutes after the conclusion of the game a full account of it was set up in type and within an hour or so an "extra" was selling in the streets of New York containing a vivid and detailed description of the match. By proper organization this *fin de siècle* method of reporting distant events can be made to give startling evidence of newspaper enterprise in a variety of different ways, and in the long-distance telephone system the newspapers undoubtedly have a powerful and valuable addition to their means for collecting and transmitting the "latest intelligence."



A Section of the Long-Distance Switchboard.

XVIII.

One of the chief difficulties that the Long-Distance Company met with in introducing its service to the public lay in the repugnance of heads of firms to use the telephone themselves.

It must be borne in mind that the long-distance service is chiefly useful to people having important private communications to make, such as the exchange of quotations between branch houses of bankers' and brokers' firms, consultations between lawyers, the transmission of confidential orders from the head office in town to the factory in the country and a host of other transactions of a special character which would ordinarily require personal interviews or the employment of responsible messengers. In order, then, to bring the advantages of the long-distance telephone system home to those for whom they were intended it was necessary to induce men to use the telephone who had never used it before, but had always left it to the mercy of office boy or clerk. Considerable difficulty was experienced in doing this, as many people on the first occasion of using the telephone persist in saying that they can hear nothing and working themselves into such a nervous state that in a short time they can say nothing either. It is not often taken into account that the telephone, while being the most delicate electrical instrument known, is the only one that the general public actually uses, and the general public, or a considerable proportion of it, is rather slow to learn how to use the telephone properly. It was no easy task to convince heads of firms that they really could use the telephone themselves with perfectly satisfactory results, but the Long-Distance Company succeeded in doing it and its patrons have become so finely educated in the manipulation of transmitter and receiver that they conduct their telephone interviews in the most business-like and matter-of-fact manner.

The prelude to the ordinary telephone conversation between persons to whom telephonic communication is not strictly a regular item in the daily round of business is something like this:

"Hello! Hello! Hello!"
"Hello! Hello! Well, who is it?"
"Hello! Who are you?"
"Who are you?"
"Oh! Well, this is Jones. Who are you?"
"Oh! Is that you, Jones?"
"Yes, I'm Jones. Who are you?"
"I'm Brown."
"What? Who?"

A Long-Distance Booth with Desk Set.

"This is Brown. How do you hear me?"
"Oh! Is that Brown?"
"Yes. Brown. How do you hear me?"
"Oh! I hear you pretty well. How do you hear me?"
"Oh! I hear you well enough."

"Well, what I wanted to say was that—Hello! Did you get that?"

"Yes go on, I hear you better now."

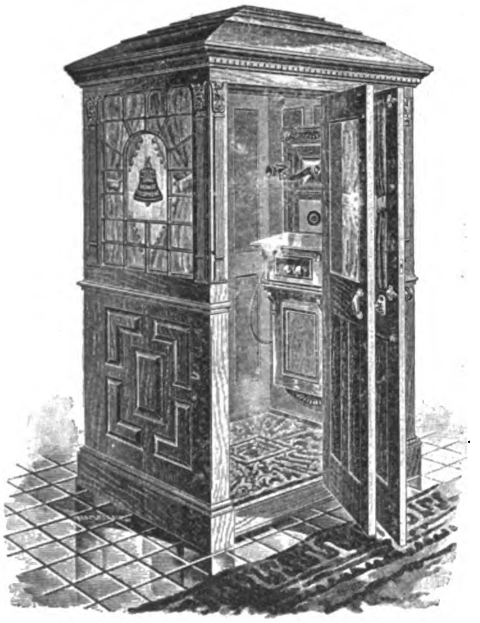
"Oh! all right. Well what I wanted to know was"—and so on.

Practised users of the long-distance wires indulge in no such extended preliminaries. For one thing conversations are generally by appointment and the parties are usually known to each other; while a second reason for promptitude is that the time allowed is limited and the line is being paid for all the time. Moreover the clearness of transmission is such that well-known voices are recognized at once and there is no more room for misunderstandings than there would be in an ordinary conversation when the talkers were in the presence of each other and only a few feet apart. The opening of a long-distance conversation is generally confined to simple salutations such as:

"Hello Smith!"

"Yes."

"This is Robinson. We have had an application from Blank & Co., of Detroit, for a consignment of goods on commission, what do you know about them?" and so on, until all the various matters to be discussed are reeled off without breaks or repetitions.



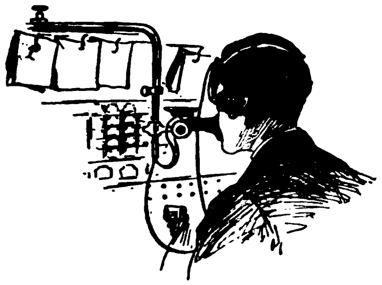
A Long-Distance Booth with Wall Set.

A surprising feature of long-distance telephony is the remarkable amount of business that can be crowded into a very short conversation. The fact that the communication obtained is an actual conversation at first-hand between the persons most directly interested in the matter under discussion is what renders the telephone so far superior to the telegraph for very many purposes. Question and answer are exchanged immediately without the annoying delays incident to telegraphic despatches. Propositions can be made and commented on, modified or rejected, in a manner quite impossible by telegraph; in fact all the advantages of a personal interview are obtained without the expenditure of time and trouble involved in a journey. Numerous instances could be given of the number of business questions that can be disposed of in a single talk over the wires within the minimum time of five minutes. Probably the best on record is that where two business men, one New York and one in Boston, discussed and settled four entirely distinct affairs in one minute and a half. Two of the matters dealt with involved large sums of money, but the men were able to lay their heads together, figuratively speaking, so well, although literally they were so far apart, that it took them but a few seconds in each case to decide on what should be done. It can readily be imagined how many telegrams would have been required to do the same amount of business, leaving entirely aside the question of time, which is so often of the first importance. Every day cases occur where the long-distance telephone enables business to be done that the telegraph cannot aid and where the only alternative would be a long and expensive journey. For instance, not long ago a New York man was notified that his draft on a house in a town far up in the interior of the State had been allowed to go to protest, and in order to protect his interests he was on the point of undertaking a journey that would have kept him away from his office for three days when a friend advised him to telephone to the bank who held the draft. He did so immediately; the bank informed him of the state of affairs and recommended a lawyer in the town to take the job in hand; he had an interview by telephone with the lawyer and gave him instructions to proceed, and the same afternoon the lawyer reported that he had got out an attachment and that the draft would be fully covered. The time spent by the New York man over the affair might have been an hour, and the total expense was for three conversations, one with the bank and two with the lawyer, as against an absence from town of two or three days and travelling expenses amounting to $40 or $50. The actual saving of time and money is by no means the only recommendation in favor of long-distance telephone communication. Often it renders possible the transaction of business which could be done in no other way, and many a time a five minutes' conversation pays for itself a thousand-fold. To manufacturers having their head offices in New York, branches in other cities and towns, and factories somewhere in the country, the service has become practically indispensable; the periodical daily talks between the chief of the firm and the manager of the factory or branch office place all their affairs so thoroughly in touch with each other that no manufacturing concern who has once adopted the service to its needs would be without it for a single day were the cost twice what it is. Bankers, brokers and lawyers form another large class of patrons, but it was among the manufacturers that the long-distance telephone first "caught on" and they have steadfastly availed themselves of it from the time of its establishment as a commercial means of communication.

XIX.

The excellent transmission over the long-distance lines has made it possible to organize a novel kind of entertainment in the form of telephonic concerts. When the system is extended to a new place the capabilities of the telephone are sometimes shown off to an admiring public by giving an inaugural telephonic entertainment the programme being made up of vocal and instrumental music and recitations delivered at New York or some other distant point and transmitted over the wires to the concert hall. These telephonic entertainments have a great fascination for the public and they are remarkably effective in showing the telephone at its very best. The Long-Distance Company has taken considerable pains in arranging transmitters and receivers suitable for the transmission of music and the dissemination of the sound through a large hall. It will be remembered that the chief attraction of the electrical exhibition held about two years ago at the Lenox Lyceum, in New York, was the telephone exhibit, where the performances at several of the New York theatres were on tap during the evening, recitations were given from Boston and the roar of Niagara Falls could be heard over the long-distance wires. Quite elaborate concerts have been given in New York and every note has been clearly transmitted to audiences assembled in Boston, Washington and Philadelphia. Not very long ago an entertainment conducted in New York was delivered at the same time to three separate and distinct audiences, one in Philadelphia, one in Baltimore and one in Washington. A general programme was announced over the wires by a speaker in New York before the concert began and each number was separately announced in the same manner. The ensemble of the orchestra was perfectly reproduced in each place and the solos rang out as distinctly and clearly as if the singers had been in all three places at once. After each performance thunders of applause came rolling over the wires from Washington, Baltimore and Philadelphia.

Another interesting example of the transmission of music by telephone occurred about a year and a half ago, when Strauss's famous orchestra was performing at the Madison Square Garden. A telephonic entertainment was given from New York to a large audience assembled at the Grand Union Hotel at Saratoga. A circuit was run from the Long-Distance Company's operating-room to the Madison Square Garden and selections from the concert given by the Strauss orchestra were switched on in alternation with flute and cornet solos, songs, glees and recitations given by musicians and vocalists assembled at Cortlandt street. The performance was heard all over the room at Saratoga by means of a single loud-speaking receiver provided with a large funnel-shaped resonator to magnify the sound. On the same evening Mr. A. S. Hibbard, the general superintendent of the Long-Distance Company, was entertaining a number of friends at his house in Morristown, N. J. Mr. Hibbard's private line was connected at Cortlandt street with the circuit running to Madison Square and the strains of the famous orchestra were heard so plainly in the house at Morristown that the guests there assembled danced to Herr Strauss's waltzes as if he had been waving his baton under the same roof instead of under one nearly 30 miles distant.



"*Good Bye.*"

QUARTZ FIBRES FOR SUSPENSION PURPOSES.

In the electrical laboratory of Queen & Co., Philadelphia, have recently been made a series of careful experiments upon the properties of quartz fibres for use in suspending galvanometer systems and in other physical measurements, as compared with fibres of glass, metal and cocoon silk. These tests have shown conclusively that quartz fibres are so greatly superior to all others in every way that the above-mentioned firm have decided to prepare them for sale, and the following details will be of much interest to our readers.

These fibres are drawn in the oxy-hydrogen flame from pure rock quartz, their diameter being regulated by the speed of drawing. As to size it is possible to draw them from those too fine to manipulate (less than $\frac{1}{10000}$ inch) up to rods $\frac{1}{10}$ inch in diameter, and in lengths (for diameters less than $\frac{1}{10000}$ inch to $\frac{1}{100}$ inch) as desired. Inspection with a microscope shows that they are extremely uniform in diameter and contain no "fishes" or flaws of any kind.

The principal advantages possessed by quartz fibres over all others are, first, perfect elasticity; they show absolutely no "Nachwirkung" or "set" and, when twisted, come back to the same position immediately; it is thus possible to reach a much higher degree of sensibility with a galvanometer using a quartz fibre in place of unspun silk, for, as is well known, a cocoon fibre, to which is attached a system under small controlling force will not return at once to the zero point within five per cent. of the total deflection. Quartz fibres are also absolutely unaffected by ordinary changes of temperature or atmospheric conditions, whereas silk fibres, absorbing greater or less amounts of moisture at different times will have correspondingly different zero points.

The tensile strength of quartz fibres is from 50 to 70 tons per square inch which is nearly as great as the best steel, and many times that of silk. Fibres of extreme fineness may, consequently, be used; as for example, a quartz suspension $\frac{1}{10000}$ inch in diameter will sustain a weight of one-half gram. They are, however, very easily broken by lateral stress and they are therefore raised or lowered as a whole instead of attempting to bend them around a spindle, although the finer ones can be successfully wound upon spindles of one-half inch or greater diameter.

The uses of quartz fibres are various; they can be employed advantageously for the suspension of all delicate electrometer and galvanometer suspensions. They may also, as suggested by Mr. Boys, be used to suspend very small bodies, the specific gravities of which are required, as there is practically no capillary attraction between the fibre and water. Being unaffected by heat and of very uniform diameter they are excellent for use as cross-hairs in telescopes and microscopes.

For further information regarding quartz fibres see a paper by C. V. Boys "On the Production Properties and Some Suggested Uses of the Finest Fibres," *Philosophical Magazine*,, 1887; also a paper by Prof. Richard Threlfall on "Elastic Constants of Quartz Threads," *Ibid*, 1890.

SHORT'S METHOD OF STOPPING ELECTRIC LOCOMOTIVES.

Heretofore in electric railway work it has been largely customary to reverse the current in order to stop the car quickly, which results in a considerable waste and causes a tendency to burn out the motors. In order to obviate this difficulty, Mr. Sidney H. Short, of Cleveland, Ohio, has devised an arrangement by means of which the motors are disconnected from the ordinary supply-wire and connected in a local circuit with each other in such a way that the current generated in the local circuit and acting on a motor, tends to check the forward movement of the car. The two motors of a car are connected in the local circuit so that the electromotive force of each under the rotation imparted by the forward movement of the car opposes that of the other and tends to produce a current in such a direction as to increase its own field magnetism and cut down that of the other. The car will thus be checked or brought to a sudden stop if running rapidly, and, if on a heavy grade, will creep slowly down without taking current from the supply wire and without having the brakes set. In effecting this, one motor overpowers the other, owing to the difference in the residual magnetism of their fields, and reverses the field polarity of the weaker motor, which is thereupon operated in such a direction as to run the car backward by the current from the more powerful motor, acting as a generator.

REPORTING AN ENGLISH BOAT RACE.

The celerity of telegraphic communication was well exemplified at the recent Oxford-Cambridge University boat race on the Thames. The press boat, as it steamed up the Thames, paid out a cable over the whole length of the course, and at each important part of the race a telegraphic message was despatched by the Press Association. The result was that within a minute of the boats passing any well-known landmark, the clubs in London were informed of their positions. Furthermore, papers were to be bought in Trafalgar Square giving full details of the race at 12.41, within six minutes of the arrival of the Oxford crew at the winning post.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed*, Editor of The Electrical Engineer, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements. - *We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

Vol. XIII. NEW YORK, MAY 11, 1892 No. 210.

> ***The truth of science has ever had, not merely the task of evolving herself from the dull uniform mist of ignorance; but also that of repressing and dissolving the phantoms of imagination which ever rise up in new and tempting shapes, and which not being of her, crowd before and around her and embarrass her way.—Faraday.***

THE EDISON TELEPHONE PATENTS.

THE American Bell Telephone Company have been in some respects singularly fortunate in the essential character of the patented inventions upon which their business has been based. The original invention of Alexander Graham Bell has been held by repeated adjudications of the courts to embody a novel art or process of transmitting articulate sounds by undulatory vibrations of electricity. Not only that, but a very general consensus of opinion among scientific men has been that no method of transmission of speech by electricity other than by means of undulatory currents, is in the least likely to prove practicable and successful. It follows, therefore, as Justice Gray held in the Dolbear case in 1883, that "if that art or process is the only way by which speech can be transmitted by electricity, that fact does not lessen the merit of his (Bell's) invention, or the protection which the law will give to it."

Soon after the invention of Bell began to be practically used, it became apparent that for speaking over lines of any length superior results might be expected if a practicable means could be discovered of varying the strength of a battery current by the action of the vocal vibrations, a conception which Bell himself had suggested in his patent. Contacts of variable resistance made of carbon were soon found to be the desideratum, and it is a singular fact that, although thousands of substances have been tested and years of experiment have been devoted to the subject, carbon remains to-day practically the only known material which will satisfactorily fulfil the conditions of this service.

In the year 1877 and subsequently a number of applications for patents were filed by different inventors of telephone transmitters making claim, in one form and another, to the "carbon contact," and after the lapse of 15 years, due to protracted proceedings in the Patent Office to determine who was the original and prior inventor, the contest terminated in the issue on May 3, 1892, to the Western Union Telegraph Company, as assignee of Thomas A. Edison, of three patents, one of which is a broad patent covering the use of a carbon contact in a telephonic transmitter; which patents, under the provisions of an existing contract, will inure to the benefit and behoof of the American Bell Telephone Company.

The text of the most important patent, omitting certain portions referring solely to an electro-chemical receiver, (which are not relevant to the matter under discussion), is given elsewhere in our columns. It would appear that inasmuch as this patent covers the use of "plumbago"—which is a well-known form of carbon—as well as "other similar inferior conductor," it resembles the Bell patent in the particular that it claims the only instrumentality, so far yet known, by which speech can be successfully transmitted by the variation of a battery current, and hence unless some other means of varying the current can be discovered which does not involve the use of semi-conducting electrodes at the points of contact of the circuit, this patent, if sustained, will effectually protect the most important and valuable portion of the business of the American Bell Telephone Company.

In discussion of the question of the probable validity of the patent two points may be taken to be pretty well established: first, that Edison was the prior inventor of the combination he has claimed, and second, that no legal presumption against the validity of the patent necessarily arises from the fact that it has been pending fifteen years in the Patent Office and that meantime the invention has gone into extensive public use all over the world.

The impression appears to be quite general that there exists an unsettled question of priority between Edison and Hughes in reference to the discovery of the microphone. However this may be, it is a question wholly aside from the present one; for the records show that Edison's invention, now patented, must have been made prior to July 9, 1877, while the earliest publication of Hughes's experiments, in which he described carbon contacts, was not made until May of the year following. As to the other point, it is sufficient to cite the well-known case of the Simpson patent on gutta-percha insulation for electric wires, the application for which was pending in the Patent Office from 1848 to 1867, a period of 19 years, during which the invention was in universal use everywhere. The patent was nevertheless sustained almost without question on this point, although the merit of the inventor was much less obvious than it is in the present case.

The most important question which will arise in the adjudication of this patent will doubtless be in connection with the much-discussed statute limiting the life of a domestic patent by that of the prior foreign patent for the same invention having the shortest time to run. In the present case there are at least nine foreign patents for substantially the same invention, all of which bear date subsequent to the application, but prior to the grant, of the domestic patent. Some of these foreign patents as, for instance, the British patent of July 30, 1877, have already expired; others are, presumably at least, still in force. The real question is therefore, is it the date of the application or the date of issue of the domestic patent that is to govern? The decisions of the circuit courts on this point have been various and conflicting, but the more recent ones appear to have pretty consistently held that the date of *issue* is the controlling one, and hence that the expiration of a foreign patent of prior date, would, upon principle, render the domestic patent void *ab initio*. But in the case of *Bate Refrigerating Co.* v. *Hammond*, decided by the Supreme Court on appeal from the Circuit Court, the decision of this question was studiously evaded. The court expressly declined to pass upon the affirmative proposition that the priority of the foreign patent is determined by the respective dates of application for the foreign and domestic patents, and not by the date of issue of the domestic patent. As the law now stands, therefore, it would seem that the Edison telephone patents are void; but when the question comes squarely before the Supreme Court for decision, as it undoubtedly will in due time, it is perhaps an even chance whether the decisions of the circuit courts will not be overthrown. This delightful state of legal uncertainty as to the very existence of a property of enormous possible value, is a significant commentary upon the results of an absurd provision which was injected into the patent law, nobody knows by whom, or for what purpose, unless it may perchance have been for the benefit of patent lawyers, to whom it has certainly proved a veritable bonanza.

THE COST OF ELECTRICITY IN AGRICULTURE.

The proposal to employ new methods in any department of work, which has been subject to practically no change for long periods of time, naturally arouses the interest of all concerned, especially if the proposed change promises to bring about large economy in operation or production. The experiments which are now being undertaken by the Department of Agriculture in the application of electric motive power to the operation of farm implements therefore have a wide significance; for if it can be shown that there, as in the case of the street railway, the horse can be properly displaced by the electric motor, an enormously wide field will be opened to the latter. Recent articles in The Electrical Engineer, by Mr. A. A. Denton, of the United States Experimental Agricultural Station at Sterling, Kansas, have well shown the advantages which could be derived from the application of the electric motor to farming operations. The cost of electric motive power as compared with horses must, of course, be the deciding factor in this intended change, and we have, therefore, thought it well to bring out the results arrived at by Prof. R. C. Carpenter, of Cornell University, on this point, in order to point out some apparent discrepancies which are apt to lead to a misunderstanding of the true nature of the problem involved.

Taking up the question of the power to operate the motor, Prof. Carpenter assumes that it would require a 75 h. p. engine and boiler to develop 25 h. p. at the motor shaft. Based on these figures he calculates the cost of such a system approximately as follows:

Cost of 75 h. p. steam plant	$3,750 to	$4,500
Cost of dynamo, 60 h. p. at $30	1,800 "	1,800
Cost of 25 h. p. motor	1,000 "	1,000
Cost of wire, 1 mile and return	500 "	500
	$7,050 to	$7,800
The cost per h. p. delivered (21)	326 "	372

And as to the probable cost of operation he calculates:

The engine would require 2 tons of coal per day at $4	$8.00
The help, engineer and motor man, $2 each	4.00
Making the cost of operation	$12.00
To this must be added a man or laborer	1.50
	$13.50
The cost of operating 21 horses can be taken at current rates; for man and team at $2.50 per day, it would be	$26.50
So that there would seem to be a net gain from the use of the motor of (per day)	$13.00

In the case of the team the charge is sufficient for repairs, renewals and interest. These items would certainly be in the case of the motor one-half more, so that the net saving would be less than $7 per day.

We must, however, take exception to what we believe is an overestimate on the part of Prof. Carpenter of the amount of engine power required to deliver 25 h. p. at the motor shaft. Allowing an efficiency of 80 per cent. in the generators, a like efficiency in the line, that is, a drop of 20 per cent., and an efficiency of 80 per cent. in the motor, the engine power required would still be a trifle under 50 h. p. So that not only in the item of first cost of boiler and engine and dynamo, but also in the cost of operation a considerable reduction would be permissible. Even taking Prof. Carpenter's figures as they stand, there is shown a gain in the use of the electric motor, which even on this small scale is quite appreciable.

In discussing this question an important point must not be lost sight of, namely, that to base the economy of operation upon figures representing 25 h. p. delivered, is to leave out of consideration the ultimate shape which electrical distribution for agricultural purposes would assume. For a proper basis of calculation we must assume a central station of several hundred or thousands of horse power, from which radiate lines in all directions and to a distance limited only by the potentials which are now available. The cost of producing one horse power delivered under such conditions must differ widely from the case assumed by Prof. Carpenter. Nothing could be more simple than the establishment of such a station on the alternating plan, distributing current at high pressure on small wires with numerous taps or junctions where a converter could be inserted, and from which current at low pressure could be furnished to alternating motors without commutators, which would in itself be a gain from a mechanical standpoint. By establishing numerous current outlets, the difficulties encountered in paying out long lengths of cable is avoided, and thus one of the objections to this mode of power distribution to farming implements is overcome.

We hope that the appropriation asked for in the bill introduced by Senator Peffer will be granted, for although we do not deem the amount at all sufficient to carry the experimental work to completion, it will suffice to make a start in a field of the highest importance to all engaged in electrical work. We believe, indeed, that all manufacturers of electrical apparatus ought to lend their aid and co-operation for reasons which are obvious, to the successful carrying out of these experiments.

THE PRACTICAL MANAGEMENT OF DYNAMOS AND MOTORS.—X.

BY

Francis B. Crocker and S. S. Wheeler.

CHAPTER VII (*Continued*).

4. Balance.—The perfection of balance of the armature or pulley can be roughly tested by simply running the machine at its normal speed and noting if these parts are sufficiently well balanced not to cause any objectionable vibration. Of course, practically every machine produces perceptible vibration when running, but this should not be more than a slight trembling. The balance of a machine can be definitely tested and the extent of the vibration measured by suspending the machine or mounting it on wheels and running it at full speed. In this case it is better to run the machine as a motor, even though it be actually a dynamo, in order to make it produce its own motion, so to speak, and avoid the necessity of running it by a belt which would cause vibration and interfere with the test. If, however, the use of a belt is unavoidable, it should be arranged to run vertically upward or downward so as not to produce any horizontal motion in addition to the vibration of the machine itself. Fig. 21 shows a machine hung up to be tested for balance and run either as a motor or by the vertical belt indicated as a dotted line. Any lack of balance will cause the machine to vibrate or swing horizontally, and this motion can be measured on a fixed scale.

5. Noise.—This cannot be well tested quantitatively, although it is very desirable that a machine should make as little noise as possible. Noise is produced by the various causes given in the chapters on Locating Faults. The machine should be run at full speed and any noise and its cause carefully noted.

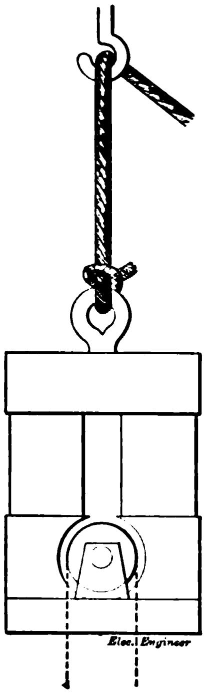

FIG. 21.

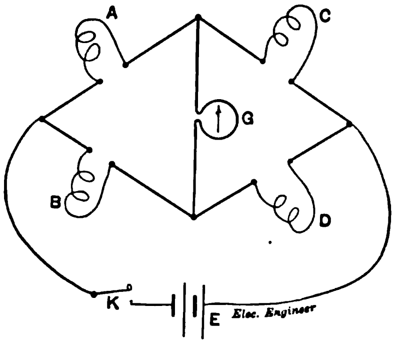

FIG. 22.

6. Electrical Resistance.—There are two principal classes of resistance tests that have to be made in connection with dynamos and motors. First, the resistance of the wires or conductors themselves, which might be called the *metallic* resistance; and second, the resistance of the insulation of the wires, which is called the *insulation* resistance. The former should usually be as low as possible, the latter should always be as high as possible, because a low insulation resistance not only allows current to leak, but also causes "burn-outs" and other accidents. Metallic resistance, such, for example, as the resistance of the armature or field coils, is commonly tested either by the Wheatstone bridge or the "drop" (fall of potential) method.

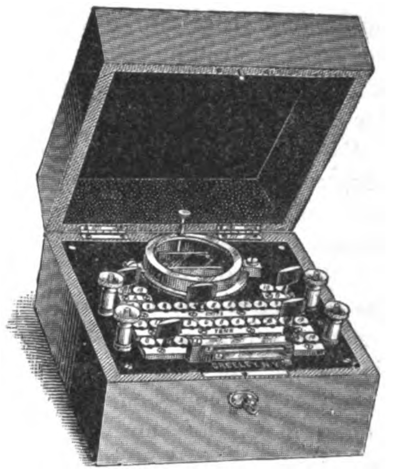

FIG. 23.—PORTABLE WHEATSTONE BRIDGE.

The Wheatstone bridge, Fig. 23, is simply a number of branch circuits connected as indicated in Fig. 22. A, B and C are resistances the values of which are known. D is the resistance which is being measured. G is a galvanometer and E is a battery of one or two cells controlled by a key K, all being connected exactly as shown. The resistance C is varied until the galvanometer shows no deflection when the key K is closed. The value of the resistance D is then found by multiplying together resistances C and B and dividing by A; that is, $D = \frac{C \times B}{A}$. A very convenient form of this apparatus is what is known as the portable bridge. This consists of a box containing the three sets of known resistances A, B and C controlled by plugs, also the galvanometer G and key K, all connected in the proper way. In some cases the perfection of convenience is reached by including the battery E in the box also, but ordinarily this is not done and it is necessary to connect one or two cells of battery to a pair of binding posts placed on the box for that purpose. Resistances from $\frac{1}{10}$ ohm to 100,000 ohms can be conveniently and accurately measured by the Wheatstone bridge. Below $\frac{1}{10}$ ohm the resistances of the contacts in the binding posts and plugs are apt to cause errors. In fact, in measuring any resistance care should be taken to make the connections clean and tight. The ordinary bridge will not measure above 100,000 ohms because if the resistance in the arm B is 100 ohms, 1 ohm in A, and 1,000 ohms in C, then D is 100,000. Sometimes the arms A and B are provided with 1,000-ohm coils in addition to the usual 1, 10 and 100 ohm coils, or sometimes the arm C contains more than 1,000 ohms in all; in either case the range will be correspondingly increased. The bridge may be used for testing the resistance of almost any field coils that are found in practice. Shunt fields for 110-volt machines usually vary from about 100 or 200 ohms in a 1 h. p. machine to about 10 or 20 ohms in a 100 h. p. machine. If the voltage is higher or lower than 110 these resistances vary in direct proportion. Series fields for arc circuit dynamos or motors vary from about 1 to 20 ohms.

The bridge may also be used for testing the armature resistance of most machines. But 110-volt shunt machines above 10 h. p. usually have resistances below $\frac{1}{10}$ ohm, which is below the range of the bridge, as already stated. Higher voltage dynamos and motors have proportionally higher resistance armatures. Arc machines have armatures of about 1 to 20 ohms resistance and are therefore easily tested by the bridge.

The "drop" or fall of potential method is well adapted to testing the armature resistance of large incandescent dynamos or the resistance of contact between commutator and brushes or other resistances which are usually only a few hundredths or even thousandths of an ohm. This consists in passing a current through the armature and a known resistance of, say, $\frac{1}{100}$ ohm connected in series with each other, as represented in Fig. 24. The "drop" or fall of potential in the armature and in the known resistance are then compared by connecting a galvanometer first to the terminals marked 1 and 2 and then to 3 and 4. The deflections of the needle in the two cases are proportional to the resistances. The current needed depends upon the sensitiveness of the galvanometer, but should not require more than a few cells of battery. If a galvanometer is not at hand, the drop method can be used with a strong current and a voltmeter, the connections being the same as in Fig. 23. The current required in this case depends upon the resistance to be measured, but it must of course be sufficient to produce a readable deflection on the voltmeter. Usually 10 to 100 amperes and a voltmeter reading to a single volt or fractions of one volt are needed for low resistances.

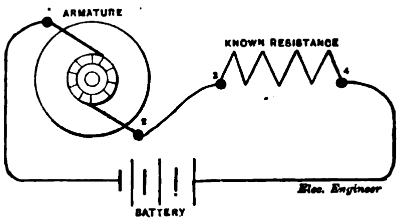

FIG. 24.

It is wise to start with a small current and increase it until a reasonably readable deflection is obtained on the voltmeter. The current may be obtained by using a cell of storage battery, or a few cells of some strong primary battery such as a plunge battery, Bunsen or bichoromate battery. The current may also be taken from another dynamo or from a circuit, but a bank of lamps or a liquid resistance should then be used to control the current, as the armature alone, of course, has very little resistance. A convenient form of liquid resistance for this purpose is described hereafter in the directions for testing current (No. 8.)

The insulation resistance of a dynamo or motor, that is, the resistance between its wires and its frame should be at least one megohm per hundred volts E. M. F., and it is, of course, better if it is much higher. It is therefore beyond the range of ordinary Wheatstone bridge tests, but there are two good methods which are applicable—the "direct deflection" method and the voltmeter method. The direct deflection method is carried out by connecting a sensitive galvanometer such as a Thomson high resistance reflecting galvanometer (tripod or square pattern) in series with a known high resistance, usually a 100,000 ohm rheostat, a battery and a key as shown in Fig. 25. The galvanometer should be shunted with the $\frac{1}{999}$ coil of the shunt so that only $\frac{1}{1000}$ of the current passes through the galvanometer, the machine being entirely disconnected. The key is closed and the steady deflection noted. It is well to use only one cell of battery at first and then increase the number if necessary until a considerable deflection is obtained. One of the wires is then connected to the binding post or commutator of the dynamo or motor and the other to the frame or shaft of the machine as indicated by dotted lines. The key is closed and the deflection noted. Probably there will be little or no deflection on account of the high insulation resistance, and the shunt is changed to $\frac{1}{99}$, $\frac{1}{9}$ or left out entirely if little deflection is obtained. In changing the shunt, the key should always be open, otherwise the full current is thrown on the galvanometer. The insulation is then calculated by the formula: Insulation resistance $= \frac{D \times R \times S}{d}$, in which D is the first deflection without the machine connected and d the deflection with the insulation in the circuit, R the known high resistance and S the ratio of the shunt. That is, if the shunt is $\frac{1}{999}$ in the first test and $\frac{1}{9}$ in the second, then S is 100, and if the shunt is out entirely in the second test S is 1,000. It is safer to leave the high resistance in circuit in the second test to protect the galvanometer in case the insulation resistance is low. Therefore this resistance must be subtracted from the result to obtain the insulation itself. By the above method it is possible to measure 100 megohms, or even more. The wires and connections should be carefully arranged to avoid any possibility of contact or leakage which would spoil the test.

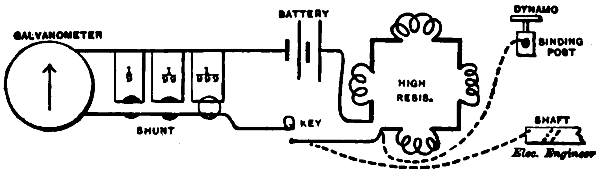

FIG. 25.

The voltmeter test for insulation resistance requires a sensitive high resistance voltmeter such as the Weston. Take, for example, the 150-volt instrument which usually has about 15,000 ohms resistance; apply it to some circuit or battery and measure the voltage. This should be as high as possible; say, 100 volts. The insulation resistance of the machine is then connected into the circuit as indicated in Fig. 26. The deflection of the voltmeter is then reduced in proportion to the value of the insulation resistance. The insulation is then found by the equation : Insulation resistance $= \frac{D \times R}{d} - R$, in which D is the first, and d the second deflection and R the resistance of the voltmeter. If the circuit is 100 volts then D is 100 ; and if d, the deflection through the insulation resistance of the machine, is 1 division, then the insulation is: $(100 \times 15{,}000) - 15{,}000 = 1{,}485{,}000$ ohms. This method does not test very high resistances, but if little or no deflection is obtained through the insulation resistance it shows that it is at least several megohms, which is high enough for practical purposes.

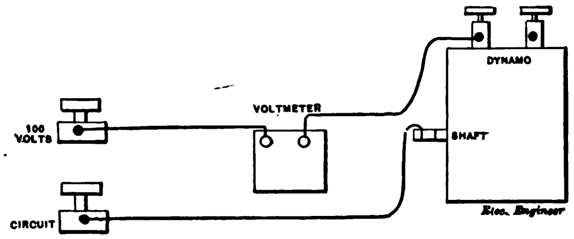

FIG. 26.

The ordinary magneto bell may be used to test insulation by simply connecting one terminal to the binding post of the machine and the other to the frame or shaft.

A magneto bell is rated to ring through a certain resistance, usually from 10,000 to 30,000 ohms, and if it does not ring it shows that the insulation is more than that amount. This limit is altogether too low for proper insulation in any case, and therefore this test is rough and really only shows whether the insulation is very poor or the machine actually grounded.

THE BUCARAMANGA, U. S. C., ELECTRIC LIGHT PLANT.

The electric light is making steady progress in South and Central America, and several electric light stations recently installed in those regions have been described in our columns. Among the plants which have been particularly successful from the start is that now in operation at Bucaramanga, U. S. of Colombia, which was installed by Mr. Julio Jones for the Thomson-Houston International Electric Co., and, considering the obstacles encountered, reflects great credit on his perseverance and ability. These obstacles were numberless, some arising from natural causes, some from the great backward state of civilization of the country, and some from evil spirit in the people. Among the first may be mentioned the difficulties in transportation of the heavy pieces of machinery, the total weight of which amounted to about 25,000 pounds. This, of course, refers only to pieces weighing between 200 and 1,400 pounds, all small apparatus having been packed in 150-pound packages for mule transportation, so that a mule could carry two such packages weighing 300 pounds at the most. But even with this weight it is a wonder that a mule can travel over the mountains through such roads as there exist. All the small packages were carried by about 200 mules.

Of the 25,000 pounds about one-half consisted of pieces under 400 pounds weight and such were carried by oxen, some on their backs, others dragged over the ground on frames of timber, it being impossible to make use of carts or any wheeled vehicles on such roads, the condition of which is almost beyond description. In some parts stones of great size lie across the road, leaving narrow passages of only two or three feet width; in others the ground has the shape of a V and then this sort of canal, called a road, is curved or zigzagged for the purpose of climbing up a steep hillside, reducing the grade of the road to about 30° or more, and making it a sort of staircase, some steps of which are so high, that mules which are not strong enough fall right back on the top of their load in attempting to jump up. And it was over such roads that pieces which weighed as much as 1,400 pounds had to be carried by men on their shoulders for a distance of about 25 miles. Such pieces would take not less than 60 men each, the modus operandi being to tie two long poles of wood to the piece, one on each side and then short ones across these two for the men to put their necks under. Pieces aggregating a weight of about 12,500 pounds were carried by such means.

But there was another transshipment which is perhaps of greater interest, the transportation in canoes through a portion of the Lebrija River, which had never until then been navigated. Coming from the coast, the city of Bucaramanga is reached as follows: First, ascending the Magdalena River by steamer to the mouth of the Lebrija River which is not navigable for steamers; here transshipped to canoes or "dug outs." These canoes are about 30 or 40 feet long, 3 to 5 feet wide and 2 to $2\frac{1}{2}$ feet deep, and are manned by negroes, called "bogas"; the canoes are laboriously poled up the stream by six or seven of these men.

The Lebrija is thus navigable up to the port named Botijas, about 35 miles from the city. From this place up it is almost impossible to navigate, as the rapids become more frequent, and exceedingly dangerous; and yet for the purpose of avoiding a piece of road over a mountain, through which it would have been quite impossible to travel with the larger pieces of machinery, it became indispensable to continue the navigation for about eight miles up to a place where they could be landed near the road and thence carried away. In some of these rapids they had to make use of a winch, which after being secured in some convenient place above the rapid, served to pull up the canoe with a strong cable. What this task was, can be conveyed best by stating that it took three days of hard labor to go up the eight miles, and only 30 minutes to go down. Three such trips had to be made with two canoes each time, in order to transport all the heavy machinery, the direction of the work being taken personally by Mr. Jones.

Having landed the materials on the ground, next came the construction of the station on the side of the Surata River, which offered serious difficulties in consequence of the great scarcity of laborers, and want of intelligent and skilled workmen, especially of masons, not one being found that knew his business, besides a complete absence of facilities for doing the most ordinary kind of work; for in this land man has nothing but his hands for tools. The principal piece of machinery was a small winch, with which two men could lift about a ton, and which, applied to a crane which was set up, served to build some large stone walls,

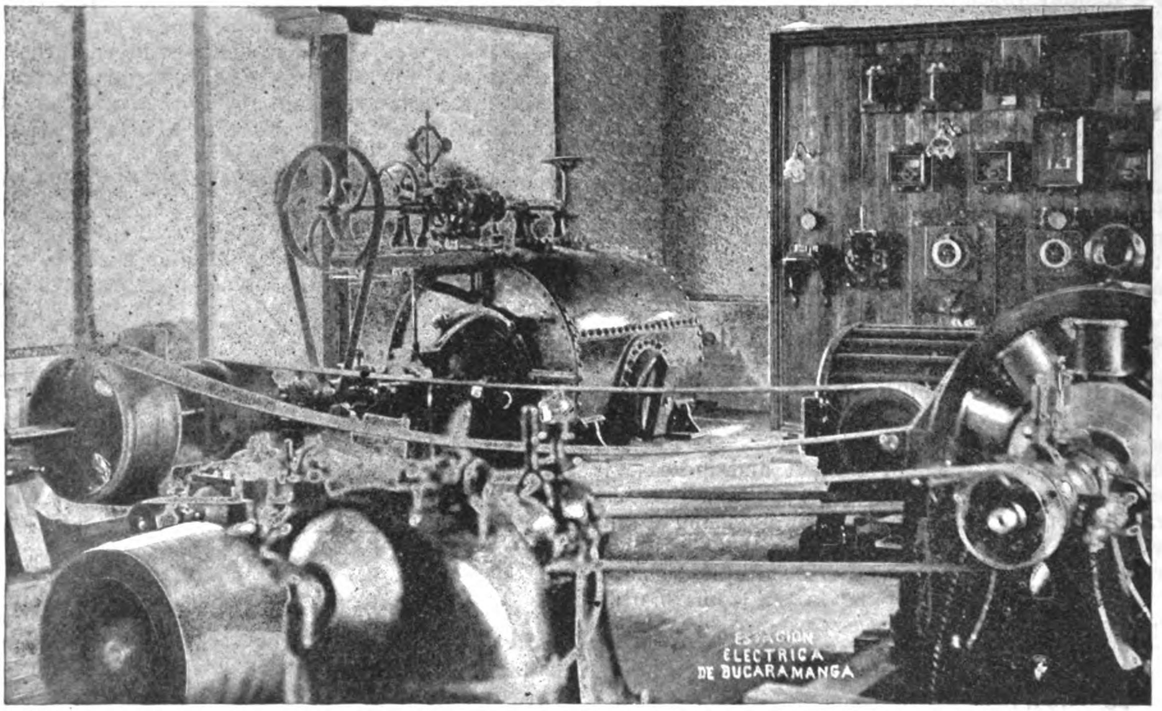

FIG. 1.—DYNAMOS AND TURBINE, BUCARAMANGA ELECTRIC LIGHT PLANT.

made out of heavy coarse stones. The place for the station had to be hewn out of a steep hillside composed mostly of huge rocks, which had to be blasted, and the construction of the ditch which runs along a steep hillside was a matter of considerable work.

Work was first begun in September, 1890, and the definite inauguration of the arc lighting took place on November 20, 1891. The incandescent light was inaugurated on December 26 of last year, and both have since been continued running together without interruption and with the greatest satisfaction.

The Bucaramanga electric station is located on the banks of the Surata River, 2½ miles away from the city. It is a two-story building largely made of stone and brick, which measures 44 x 24 feet. The upper story is divided into a large dynamo-room and a small room for the engineers. A third of the first story is occupied by the tail-race of the turbine wheels, and a water tank 13 x 19 feet, the rest forming a large room, which can, later on, be made into a dynamo-room. On one extremity of the tank there is built up an elliptical brick arch, which serves as a support for the wheels, as well as for the corresponding parts of the walls of the upper story and roof of the house. It is, consequently, very solidly built and is 13 feet span, 4 feet rise, 6 feet long and 3 feet deep. Upon this arch the flume of the turbines is solidly set, so that it occupies a corner of the dynamo-room on the second floor, as shown in Fig. 1.

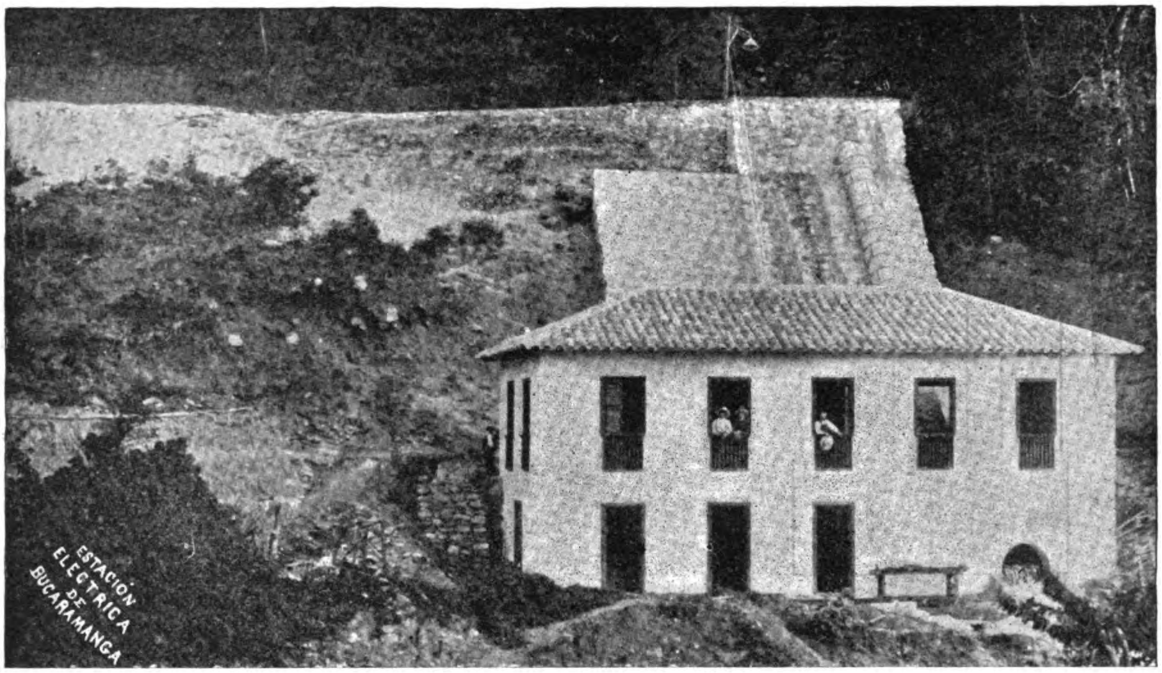

FIG. 2.—ELECTRIC LIGHT STATION, BUCARAMANGA, U. S. C.

The turbines were furnished by the Rodney-Hunt Machine Co., of Orange, Mass. They are a pair of 12-inch wheels on a 3-inch horizontal shaft encased in a steel flume, made of ½-inch steel plates 4 feet 6 inches in diameter by 4 feet 10 inches long. The penstock is built of $\frac{3}{16}$ inch iron plate and is all divided up into small pieces for ease in transportation, which pieces are all secured by bolts instead of being riveted. It is 42 inches in diameter and about 45 feet long. It comes out of a brick pressure tank, shown in Fig. 2, and tending downwards it descends at an angle of 53 degrees and finally bends again to enter the flume horizontally.

The wheels are capable of developing 160 h. p. They work under a head of 50 feet, which is divided up as follows : 5 feet in the pressure tank to the entrance of the penstock, 35 feet thence to the centre of wheels and 10 feet of draught fall. The wheel governor, which was also made by the Rodney-Hunt Machine Co., is a double-action governor, and is mounted on top of the wheel. It regulates the speed admirably, adjusting the supply of water to the wheels exactly in accordance with the expenditure of power required by electric machines. The wheels vent 2,100 cubic feet of water per minute when working at full capacity, and revolve with a speed of 780 revolutions per minute. The main shaft from which power is transmitted to the dynamos is simply an extension of the wheel-shaft, to which it is directly connected, and is likewise a 3-inch shaft.

The switchboard is placed in front of the wheels and next to it are placed in a comparatively small space the four dynamos now in use, leaving sufficient space in the same room for three more of them, there being also a surplus of power in the wheels sufficient to run another set of machines equal to those which are now in operation. The dynamo machines, all furnished by the Thomson-Houston International Electric Co., are as follows: One arc dynamo capable of maintaining 30 1,200 c. p. arc lamps; one incandescent dynamo of the alternating current type capable of maintaining 650 16 c. p. incandescent lamps by the transformer system. This machine is adjusted for 20 per cent. loss, so that it automatically maintains constant pressure at the terminals of the transformers in the city at 1,100 volts, the voltage of the transformed current being 52 volts; and an exciter dynamo for exciting the magnetic field of the alternator. This little dynamo is capable of exciting the field of four such machines; its remaining capacity is used at present for supplying the incandescent lamps at the station. There is also one 20 h. p. generator adjusted for a loss of 25 per cent., so that it automatically maintains a constant electromotive force of 500 volts at the terminals of the electric motors placed in the town.

There is a second set of potential indicators placed at the distributing station which is located in the centre of the city and there pressure is kept constant at 54 volts. The lights burn well and all with equal brilliancy throughout the city, and the people are delighted with them. Among the convenient arrangements is one for transferring the current from one lamp to another placed at a distant point by means of three-way switches, etc. At the station the lighting is done with incandescent 52-volt lamps, two in series, supplied with the current from the exciter, the pressure of which is kept at 106 volts, the wiring being laid out for 2 per cent. loss.

DYNAMO-ELECTRIC MACHINERY.—II.[1]

BY J. HOPKINSON, F. R. S., AND E. WILSON.

EFFECTS OF THE CURRENT IN THE ARMATURE.

Quoting from the Royal Society Paper, p. 342, "The currents in the fixed coils around the magnets are not the only magnetizing forces applied in a dynamo machine; the currents in the moving coils of the armature have also their effect on the resultant field. There are in general two independent variables in a dynamo machine—the current around the magnets and the current in the armature, and the relation of E. M. F. to currents is fully represented by a surface. In well-constructed machines the effect of the latter is reduced to a minimum, but it can be by no means neglected. When a section of the armature coils is commutated it must inevitably be momentarily short-circuited, and, if at the time of commutation the field in which the section is moving is other than feeble, a considerable current will arise in that section, accompanied by waste of power and destructive sparking.

"Suppose the commutation occurs at an angle λ in advance of the symmetrical position between the fields, and that the total current through the armature be C, reckoned positive in the direction of the resultant E. M. F. of the machine, *i. e.*, positive when the machine is used as a generator of electricity. Taking any closed line through magnets and armature, symmetrically drawn, as A B C D E F A, Fig. 2, it is obvious that the line integral of magnetic force is diminished by the current in the armature included between angle λ in front and angle λ behind the plane of symmetry. If m be the number of convolutions of the armature, the value of this magnetizing force is $4\,\pi\,C\,\frac{m}{2}\,\frac{2\lambda}{\pi} = 4\,\lambda\,m\,C$ opposed to the magnetizing force of the fixed coils on the magnets. Thus, if we know the lead of the brushes and the current in the armature, we are at once in a position to calculate the effect on the E. M. F. of the machine. A further effect of the current in the armature is a material disturbance of the distribution of the induction over the bored face of the pole-piece; the force along B C is by no means equal to that along D E. Draw the closed curved B C G H B, the line integral along C G, and H B is negligible. Hence the difference between force H G and B C is equal to $4\,\pi\,C\,\frac{m}{2}\,\frac{\kappa}{\pi} = 2\,\kappa\,m\,C$, where κ is the angle $C\,O\,G$."

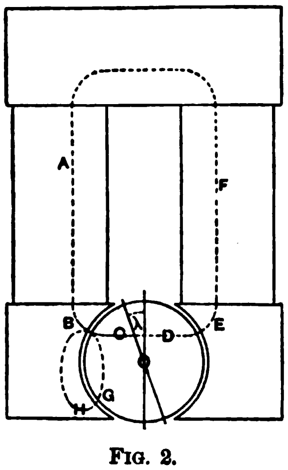

FIG. 2.

To verify this formula is one of the principal objects of this paper.

A pair of brushes having relatively fixed positions near together, and insulated from the frame and from one another, are carried upon a divided circle, and bear upon the commutator. The difference of potential between these brushes was measured in various positions round the commutator, the current in the armature, the potential difference of the main brushes, and the speed of the machine being also noted.

The results are given in Figs. 3, 4, 5 and 6, in which the ordinates are measured potential differences, and the abscissæ are angles turned through by the exploring brushes. The potential differences in Fig. 3 were measured by a Siemens voltmeter, and each ordinate is, therefore, somewhat smaller than the true value, owing to the time during which the exploring brushes were not actually in contact with the commutator segments. But this does not affect the results, because the area is reduced in the same proportion as the potential differences. In Figs. 4, 5, and 6 the potential differences were taken on one of Sir William Thomson's quadrant electrometers, and are correct.

Take Fig. 3, in which machine No. 1 is a generator. A centimetre horizontally represents 10 degrees of lead, and the ordinates represent differences of potential between the brushes. The area of the curve is 61.3 sq. cm., and represents 130 volts and a total field of $\frac{130}{104} \times \frac{1}{29} \times 10^8 = 4.31 \times 10^6$ lines of induction. This is, of course, not the actual field, which is 3 per cent. greater on account of the resistance of the armature, but is represented by an area 3 per cent. greater.

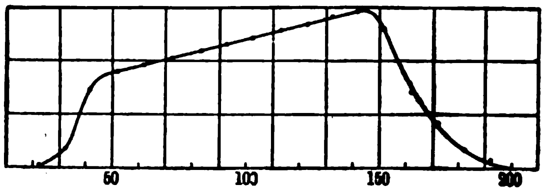

FIG. 3.

An ordinate of 1 cm. will represent an induction of $\frac{4.31}{61.3} \times 10^6 = 7.0 \times 10^4$ lines in 10 degrees. The area of 10 degrees is $39.5 \times 1.73 = 68.3$ sq. cm.[2] Hence, an ordinate of 1 cm. represents an induction of 1,024 lines per square centimetre. The difference between ordinates at 50 degrees and 140 degrees is 2.5; hence the difference of induction is actually 2,560. Theoretically, we have $\kappa = \frac{1}{2} = \pi\ m = 104\ C = 9.4$. Therefore, $2\,\kappa\,m\,C = 3{,}072$, and this is the line integral of magnetizing force round curve.

Let A be the induction at 50 degrees, and $A + \delta$ at 140 degrees; these also are the magnetizing forces. Hence, $(A + \delta)\,1.4 - A\,1.4 = 2\,\kappa\,m\,C$; $\delta = 2{,}200$ as against 2,560 actually observed.

Take Fig. 4, in which No. 2 machine is a motor. The total field $= \frac{107}{104} \times \frac{1}{20} \times 10^8 = 5.15 \times 10^6$ lines of induction. Since the area of the diagram is 53.5 sq. cm., an ordinate of 1 cm. $= \frac{5.15}{53.5} \times 10^6 = 96 \times 10^4$ lines of induction in 10 degrees. Hence, an ordinate of 1 cm. represents an induction of $\frac{9.6 \times 10^4}{68.3} = 1{,}400$ lines per sq. cm. The difference between ordinates at 320 degrees and at 230 degrees is 2.0; hence, the difference of induction is actually 2,800. Theoretically we have $\frac{2\,\kappa\,m\,C}{l} = \frac{3\frac{1}{7} \times 104 \times 11.4}{1.4} = 2{,}666$, as against 2,800 actually observed.

In Fig. 5 No. 1 machine is a generator. The total field $= \frac{52}{104} \times \frac{1}{12.6} \times 10^8 = 3.97 \times 10^6$ lines. The area of the diagram is 90.9 sq. cm., and therefore an ordinate of 1 cm. $= \frac{3.97}{90.9} \times 10^6 = 4.37 \times 10^4$ lines in 10 degrees. Hence, an ordinate of 1 cm. represents an induction of $\frac{4.37 \times 10^4}{68.3} = 639$ lines per sq. cm. The difference between ordinates at 50 degrees and at 140 degrees is 4.5; hence, the difference of induction is actually 2,877. Theoretically, we have $\frac{2\,\kappa\,m\,C}{l} = \frac{3\frac{1}{7} \times 104 \times 12.9}{1.4} = 3{,}010$, as against 2,877.

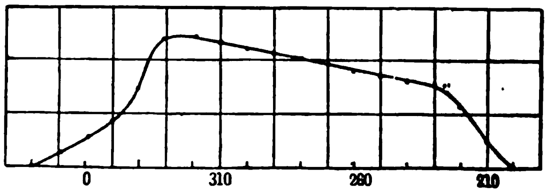

FIG. 4.

In Fig. 6, No. 2 machine is a motor. The total field $= \frac{63.5}{104} \times$

---

[1] Abstract of paper read before the Royal Society.

[2] In calculating this area, the allowance for fringe at ends of armature is taken less than before, because the form of opposing faces differs.

$\frac{1}{12.8} \times 10^6 = 4.96 \times 10.6^6$ lines. The area of the diagram 112.2 sq. cm., and therefore an ordinate of 1 cm. $= \frac{4.96}{112.2} \times 10^6 = 4.42 \times 10^4$ lines in 10 degrees. Hence, an ordinate of 1 cm. represents an induction of $\frac{4.42}{68.3} \times 10^4 = 647$ lines per sq. cm. The difference between ordinates at 323 degrees and at 238 degrees is 4.2; hence, the difference of induction is actually 2,718. Theoretically, we have $\frac{2\,k\,m\,C}{l} = \frac{3\frac{1}{4} \times 104 \times 12.3}{1.4} = 2{,}870$, as against 2,718 actually observed.

At page 345 of the paper on Dynamo-Electric Machinery it is shown that

$$I + \frac{\nu - 1}{\nu}\, 4\,\lambda\, m\, C \frac{A_2}{2\, l_2} = F\left(4\,\pi\, n\, c - \frac{4\,\lambda\, m\, C}{\nu}\right),$$

where $I = F(4\,\pi\, n\, c)$ is the characteristic curve when $C = 0$, and λ is the lead of the brushes.

The following is an endeavor to verify this formula. The potentials both upon the magnets and upon the brushes were taken by a Siemens voltmeter, and are rough. The speeds were taken by a Buss tachometer, and there is some uncertainty about the precise lead of the brushes, owing to the difficulty in determining the precise position of the symmetrical position between the fields, and also to the width of the contacts on the commutator.

It was necessary in order to obtain a marked effect of the armature reaction, that the magnet field should be comparatively small, that the current in the armature should be large, and the leads of the brushes should be large.

The two machines had their axles coupled so that No. 1 could be run as a generator, and No. 2 as a motor. The magnets were in each case coupled parallel, and excited by a battery each through an adjustable resistance. The two armatures were coupled in series with another battery, and the following observations were made:

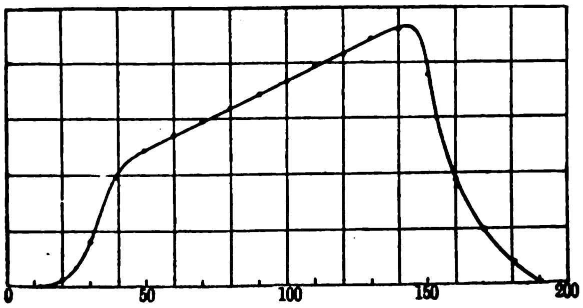

FIG. 5.

—	Potential on magnets in volts.	Potential on brushes.	Speed per minute.	Current in amperes.	Lead of brushes.
No. 1	24—24	66—67	880	102—103	26°
No. 2	29—29	86—84	880	102—103	29°

As there was uncertainty as to the precise accuracy of the measurements of potential, it appeared best to remeasure the potentials with no current through the armature with the Siemens voltmeter placed as in the last experiment. Each machine was, therefore, run on open circuit with its magnets excited, and its potential was measured.

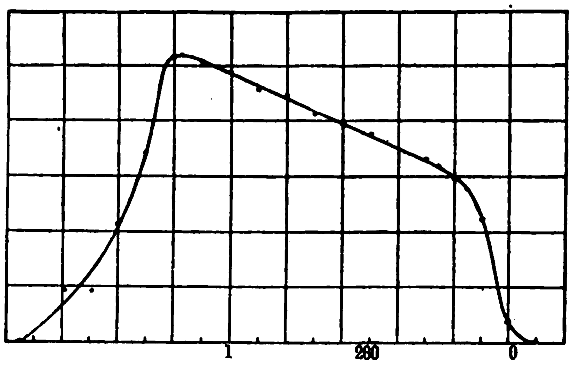

FIG. 6.

—	Potential on magnets in volts.	Potential on brushes.	Speed per minute.	Potential at 880 revs.
No. 1.	25—25	90.90	880	90.0
No. 2.	28—28	79.80	715—710	98.2

From which we infer, that we are upon a part of the characteristic which is practically straight; in which case, of course, the formula is reduced very nearly to

$$I = \frac{A_2}{2\, l_2}\,(4\,\pi\, n\, c - 4\,\lambda\, m\, C).$$

—	Potential on magnets.	Potential on brushes.	Induction $I = F(4\,\pi\, n\, c)$.
No. 1	24	86.4	2.82×10^6
No. 2	29	101.7	3.30×10^6

We have further:

$\lambda = 0.45$ for No. 1. $\lambda = 0.5$ for No. 2

$$\frac{4\, m\, C}{\nu} = 2{,}920 \qquad \frac{\nu - 1}{\nu}\, 4\, m\, C \frac{A_2}{2 l_2} = 443{,}800.$$

It has already appeared that experiment gives for I in No. 1 2.3×10^6, and in No. 2, 2.65×10^6. The difference is probably due to error in estimating the lead of the brushes, which is difficult, owing to uncertainty in the position of the neutral line on open circuit.

—	$\frac{4\,\lambda\, m\, C}{}$.	$\frac{\nu - 1}{\nu}\, 4\,\lambda\, m\, C \frac{A_2}{2\, l_2}$.	$4\,\pi\, n\, c - \frac{4\,\lambda\, m\, C}{\nu}$.	$F\left(4\,\pi\, n\, c - \frac{4\,\lambda\, m\, C}{\nu}\right)$.	$F\left(4\,\pi\, n\, c - \frac{4\,\lambda\, m\, C}{\nu}\right) - \frac{\nu - 1}{\nu}\, 4\,\lambda\, m\, C \frac{A_2}{2\, l_2}$.
No. 1 ..	1314	199700	7586	2.41×10^6	2.21×10^6
No. 2 ..	1460	221900	9290	2.90×10^6	2.68×10^6

From which we infer:

—	Currents in magnets.	$4\,\pi\, n\, c$	Corrected potential for resistance of armature.	Total induction I.
No. 1	1.78	8,900	70.8	2.30×10^6
No. 2	2.15	10,750	80.7	2.65×10^6

ELECTRIC LAUNCHES IN ENGLAND.

THE specially built electric launch constructed by Messrs. Woodhouse & Rawson, United, Limited, at their Chiswick Works to the order of the Southport Corporation, for use on their artificial lake was running during the Easter holidays with remarkable success. This boat, "The Bonnie Southport," will seat 40 persons, is 38 feet 5 inches long, has 7 feet 6 inches beam, and draws about 2 feet 3 inches of water. She is carvel built of bright mahogany, with a large counter, and is propelled by a 5 h. p. "W. & R." motor.

Reports of Companies.

OFFICERS FOR THE GENERAL ELECTRIC CO.

THE new General Electric Co. which is composed of the Edison General and Thomson-Houston Electric companies, elected its officers last Wednesday.

C. A. Coffin was elected president; Eugene Griffin, first vice-president, and Samuel Insull, second vice-president. A. S. Beves was made treasurer and assistant secretary; E. J. Garfield, secretary; J. P. Ord, comptroller; E. Clark, auditor, and B. F. Peach, Jr., and W. F. Pope, assistant treasurers.

The directors elected were: J. Pierpont Morgan, C. A. Coffin, Thomas A. Edison, D. O. Mills, F. L. Ames, T. Jefferson Coolidge, Eugene Griffin, Henry L. Higginson, H. McK. Twombly, C. H. Coster, and F. S. Hastings. Mr. Twombly was made chairman of the board.

It is possible that changes may occur later on in the constitution of the directory. For instance, it is understood that Mr. Hastings is leaving for Chicago, where he will be permanently connected with some very large interests there outside of the electrical field.

Reports have been current as to the intention to consolidate all the Canadian interests of the two companies under a large new company; and it is also rumored that one or two departments of the existing business may be turned over to new companies to be run independently under separate and distinct management.

A report has been current during the last few days that arrangements have been made by which the Edison General Electric Co., will, in all probability, give up the manufacture of electric and gas fixtures. It is also rumored that their large fixture business including the Avenue B factory property has been disposed of to a company or syndicate of capitalists, and that Mr. Samuel Insull will take the presidency of the new concern. This is important news, if true, and there seems no good reason for doubting its accuracy.

Patent Notes.

THE EDISON CARBON TRANSMITTER PATENTS.

As announced in our editorial columns last week, the Patent Office on May 3, granted to Mr. Edison several patents relating to the art of telephony, one of which is of more than usual importance on account of the scope of its claims relating to the use of plumbago or carbon in telephone transmitters. We give below an abstract of this patent upon which we comment elsewhere in this issue.

UNITED STATES PATENT OFFICE.

THOMAS A. EDISON, OF MENLO PARK, NEW JERSEY, ASSIGNOR TO THE WESTERN UNION TELEGRAPH COMPANY, OF NEW YORK, N. Y.

Speaking-Telegraph.

Specification forming part of Letters Patent No. 474,231, dated May 3, 1892.

Application filed July 20, 1877. (Model.) Patented in England July 30, 1877, No. 2,909; in Canada October 20, 1877, No. 8,026; in France December 19, 1877, No. 121,687; in Belgium January 11, 1878, No. 43,984; in Austria-Hungary January 15, 187 ; in Italy January 19, 1878. No. 9,791; in Germany January 23, 1878, No. 14,308; in Spain May 6, 1878, and in Russia February 15-27, 1882, No. 1,161.

To all whom it may concern.

Be it known that I, Thomas A. Edison, of Menlo Park, in the county of Middlesex and State of New Jersey, have invented an Improvement in Speaking-Telegraphs, (for which I have obtained foreign patents in the following countries: in Great Britain, dated July 30, 1877, No. 2,909; in France, dated December 19, 1877, No. 121,687; in Belgium, dated January 11, 1878, No. 43,984; in Italy, dated January 19, 1878, No. 9,791; in Spain, dated May 6, 1878; in Austria-Hungary, dated January 15, 1878; in Germany, dated January 23, 1878, No. 14,308; in Russia, dated February 15-27, 1882, No. 1,161, and in Canada, dated October 20, 1877, No. 8,026.) of which the following is a specification.

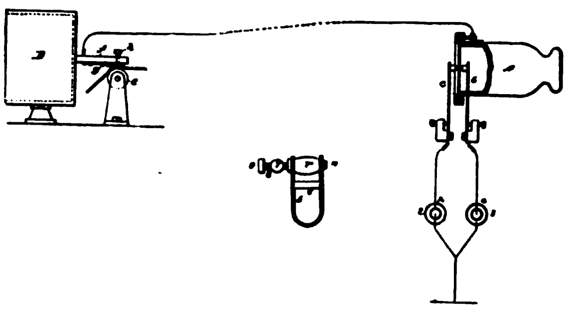
The object of this invention is to transmit the human voice over telegraphic wires for conversational purposes.

The invention consists in the use, in the circuit of a speaking-telegraph transmitter, of one or more contact-points formed of semi-conductors, such as plumbago, peroxide of lead, and other oxides and conducting material.

Fig. 1 shows the transmitter and receiver. A is the resonant chamber, over the end of which the diaphragm is stretched, either side of which may be made heavier in the center by a small weight if great amplitude is required of the diaphragm. *b c* are the two contact-springs, having points made of compressed plumbago, mixed, preferably, with gum-rubber; but any substance not liable to rapid decomposition may be used. These points face each other on the opposite side of the diaphragm and make contact with platina disks secured to the diaphragm. The spring *b* passes through a hole or small slot in the side of the transmitter. 2 and 3 are the main batteries The battery 2 has zinc to the line or point *c* and the battery 3 has copper to the line or spring *b*. When the springs *c* and *b* are adjusted so so as to make contact with the diaphragm equally, no current passes to the line; but when the diaphragm is vibrated its movement to one side—say *c*—causes a greater pressure upon the plumbago on that spring and a lessening of the pressure on the plumbago on *b*. Hence the balance of the batteries 2 and 3 will be destroyed. 2 being given the advantage will send a negative current to line. Upon the return of the diaphragm the battery-currents will again neutralize each other. The vibration of the diaphragm to the other side causes the pressure to be reversed and the battery 3 will send a positive current to the line. As plumbago decreases and increases its resistance enormously under slight changes of pressure, it follows that the strength of the electric waves will be in proportion as the speaker's voice is strong or weak.

In Fig. 2 is shown the contact-spring, which I prefer to use instead of *c* and *b*, which are used merely to assist in explaining the operations more clearly. 5 is a U-shaped spring secured to the screw 8, which is adjusted back and forward by the thumb-nut 9. 7 is the pillar holding such screws. *r* is a piece of soft rubber or equivalent substance placed between the prongs of the spring 5. 6 is a wire or band, which serves to bind the prongs tightly against the rubber *r*, so as to prevent the prongs acting as a tuning-fork and transmitting harmonic vibrations not desirable. 10 is the plumbago contact-point. The object of the U-spring and rubber is to present a semi-rigid point for contact, so as to prevent a rebound and allow of a slight yield when the plumbago is pressed by the diaphragm. D is the receiver, which consists of a resonant chamber of any suitable character, either a tube, or as a box, as at D, Fig. 1. *f* is a rigid arm secured to the box and is provided upon its extreme end with an adjusting-screw *h*. Near the end of the arm is secured a spring *g*, whose end rests upon the chemically-prepared paper upon the drum *e*. The under side resting upon the paper is platinized. The screw *h* serves to increase and decrease the pressure of the platina spring upon the paper. When the paper is moved slowly by rotating the drum *e*, the waves of electricity coming over the line pass through the arm *f* to the platinized spring *g*; thence through the paper to the earth. If a negative current passes in the opposite direction, nearly all friction between the platina plate and the paper ceases and the resonant box or diaphragm regains its normal position. When the positive current passes through the same channel, the normal friction of the paper is augmented and the chemical surface, acting upon the platina, serves to give a movement to the resonant box. Thus the mechanical force applied to move the chemical surface acts with the electric current to produce the vibration of the resonant chamber. The principle of this method of obtaining motion by electro-chemical decomposition is described in my Letters Patent No. 158,787, granted January 19, 1875. To facilitate the discharge of electricity from the receiving apparatus, it may be shunted with an electromagnet.

The mouth of the speaking-tube may be closed except a horizontal slot, through which the vibrations of the voice pass to the diaphragm or tympan, the object of the slot being to increase the power of the hissing consonants; also, the point *b* may be dispensed with on very short lines.



FIGS. 1 AND 2.

In this specification no claim is made to the use of a spring for carrying one of the electrodes, since that invention forms the subject-matter of an application, Serial No. 192,456, filed as a division hereof.

I claim as my invention—

In a telegraphic apparatus operated by sound, the combination, with the diaphragm, of one or more contact-points of plumbago or similarly inferior conductor in the electric circuit, whereby the rise and fall of electric tension is proportionate to the pressure exerted upon the said point or points by the diaphragm, substantially as set forth.

Signed by me this 9th day of July, A. D., 1877.

THOMAS A. EDISON.

In addition to the above patent there were also issued to Mr. Edison two others, Nos. 474,230 and 474,232, relating to the method of suspending and attaching the plumbago to the diaphragm so as to obtain a yielding pressure.

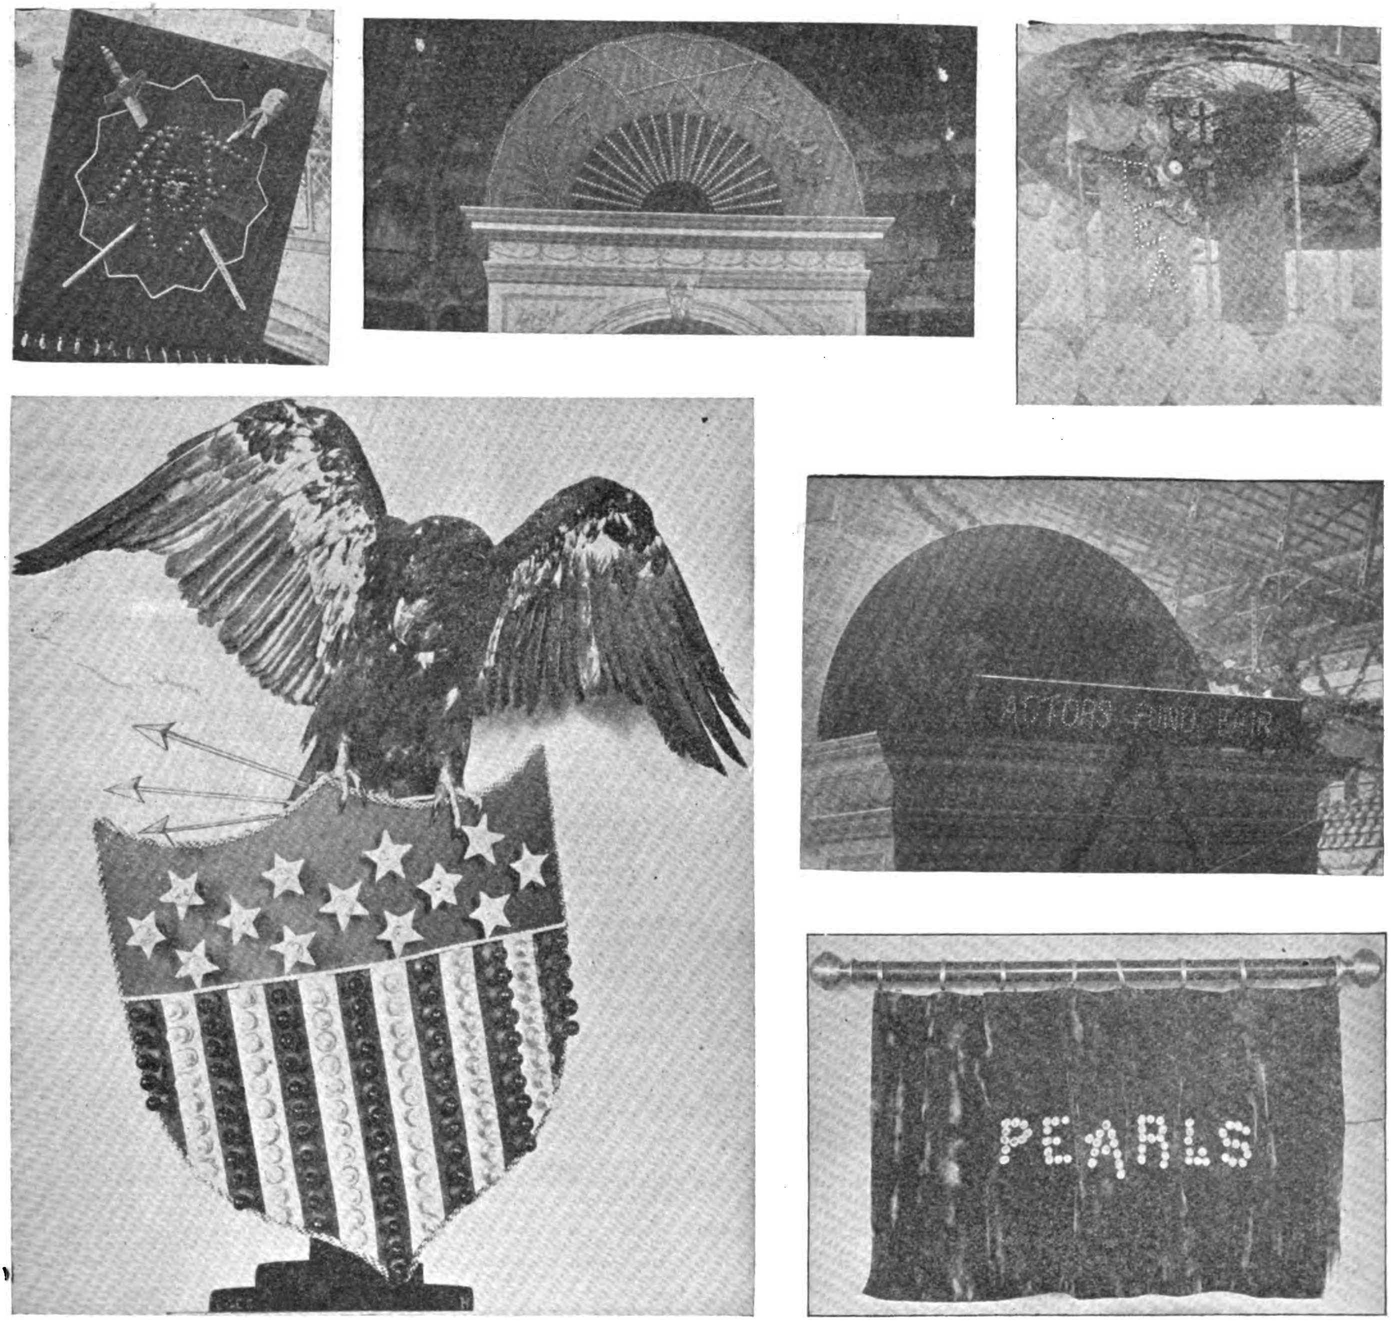
ENGINEERING EQUIPMENT COMPANY.

SOME of the recent and more important of the numerous sales of the Engineering Equipment Company, 143 Liberty street, New York, comprise line materials, poles, wire, trolleys, etc., for the several roads in the following cities: Pittsburgh, Savannah, Newark, Paterson, and Trenton, N. J., Rochester, Brooklyn, New York, Hamilton, Ohio, Chattanooga, Tenn., Elmira, N. Y., Lebanon, Pa., Johnson City, Tenn., Watertown, N. Y., San Antonio, Texas, Augusta, Ga., Colorado Springs, Hampton, Va., Cape May, N. J., Scranton, Pa., Washington, D. C., Syracuse, Buffalo, N. Y., Philadelphia, and several smaller cities in the Eastern, Middle and Southern States. The April business of the company was excellent.

The Engineering Equipment Company is pushing two of the best-known lines of railway insulating materials on the market—the Anderson "Aetna" and "G. & W." molded mica—both of which are noted for their durability and electrical and mechanical features. They are continually being improved to meet the demands of the most advanced practice. The Engineering Equipment Company has also just issued a circular, illustrating the Syracuse tubular iron poles and a variety of insulated and uninsulated tops and fittings, with a complete description of the pole, the standard sizes, weights and other data. The circular also contains some timely remarks on pole line construction by Mr. W. F. D. Crane, who has charge of the company's railway department, which will undoubtedly prove interesting and profitable to railway managers and engineers. Mr. Crane has recently contributed a portion of these practical observations to our columns.

EFFECTS WITH SMALL LAMPS AT THE ACTORS' FUND FAIR.

DURING the whole of last week, the Madison Square Gardens were occupied by a Fair, in aid of the Actors' Fund. The centre of the vast amphitheatre was filled by a number of booths chiefly in the form of reproductions on a large scale of such places as Shakespeare's house, the Globe Theatre, the Duke's Theatre, the Old Curiosity Shops, Thorne's Chatham Theatre, etc. The entrance to the arena was through a fine Roman arch and colonnade. All of these buildings were beautifully lighted by electricity, the work being done specially by the local Edison Illuminating Co., who made a very happy use of the new small lamps of the Edison General Electric Co. In many places the lamps were fastened under green bushes or in plumes of pampas grass, as well as in the more conventional brackets, sconces, etc. These 1,000 lights, added to the ordinary lights marking the lines of the dome and around the arena made the scene a veritable fairyland.



DECORATIVE ELECTRIC LIGHT EFFECTS WITH SMALL LAMPS AT THE ACTORS' FUND FAIR.

Besides these general effects; several ambitious pieces were worked out with brilliant success, and some idea of the scope of the whole display may be formed from the statement that over 10,000 lamps in the miniature sizes from 1 to 10 c. p. were used. There were 22 special designs, the largest being in the shape of a fan mounted on the entablature of the Roman arch. In this, by manipulation of a switch, the fan was made apparently to open and close every few minutes. Every shade and hue of the ornamentation was brought out clearly by the use of colored lamps. Another fine design was a U. S. shield, with each star a lamp with a three-pointed ground-glass bulb. In the centre of the dome hung a beautiful umbrella electrolier, with long pendant fringes illuminated by the lamps within. There was also a fine pinwheel, a very clever Japanese "Tea" design, an "A. O. of F." sign, two or three stars and the name of Edison. During the evening a large sign of white lamps announced that the service was given by the Edison light, but later on the reading became "Good Night." Altogether the results obtained were most gratifying to all who believe in the possibilities of small lamps. The beautiful towers at the Lenox Lyceum and at Minneapolis were a revelation of what could be done in that line; while the variety of design at the Actors' Fund Fair shows how readily the lamps lend themselves for structural effects. The Fair was visited by 15,000 or 20,000 people nightly, to all of whom the lighting was a source of infinite pleasure.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE following preliminary announcement of the programme for the annual meeting of the Institute has been issued by Mr. R. W. Pope, secretary:

The Annual Meeting of the Institute for the reception of yearly reports, the election of officers and other business of a similar character, will be held at the headquarters of the Institute, No. 12 West 31st street, at 4 p. m., Tuesday, May 17. It is expected that the session will occupy about two hours. After adjournment, those who desire to do so will assemble at "The Arena," 41 West 31st street, where a subscription dinner will be served, the price of which has been fixed at $2.00 per plate. This will be a purely social gathering, and it is hoped that all who can do so will be present.

The General Meeting will be held at the Grand Pacific Hotel, Chicago, on Monday, Tuesday and Wednesday, June 6, 7, and 8. The following papers are in preparation for that occasion and others are promised, which will be announced in the regular programme to be issued later.

1. "Electric Coal Mining Machinery," by Mr. Elmer A. Sperry, of Chicago.
2. "On the Electromagnetic Field," by M. I. Pupin, Ph. D., of Columbia College, New York City.
3. "Long-Distance Transmission for Lighting and Power," by Mr. Charles F. Scott, of Pittsburgh, Pa.
4. "A New Rheostat," by Mr. C. E. Carpenter, of Minneapolis, Minn.
5. "A Dynamo Indicator, or Instantaneous Curve Writing Voltmeter," by Prof. George S. Moler, of Cornell University, Ithaca, N. Y.
6. "Electro-Technical Education," by Prof. R. B. Owens, of the University of Nebraska, Lincoln, Neb.
7. "The Magnetic Properties of Sheet Iron," by Mr. Milton E. Thompson, of Cornell University, Ithaca, N. Y.
8. "Selective or Individual Signals," by Mr. Thomas D. Lockwood, of Boston, Mass.
9. "Railroad Train Lighting," by Mr. A. H. Bauer, of Chicago.
10. "A Discussion of Circuits Containing Resistance, Self-Induction and Capacity," by Messrs. Frederick Bedell and Albert C. Crehore, of Cornell University, Ithaca, N. Y.
11. "A Life and Efficiency Test of Incandescent Lamps," by Prof. B. F. Thomas and Messrs. P. Martin and R. H. Hassler, of the Ohio State University, Columbus, Ohio.
12. "Notes on Wiping Contact Methods for Current and Potential Measurement," by Prof. B. F. Thomas, of Columbus, Ohio.
13 "Series Electric Traction," by Mr. Nelson W. Perry, of New York City.
14. "Oil *vs.* Air as Insulation," by Dr. J. B. Williams, of New York City.
15. "On the Electrolytic Refining of Copper," by Lieut. F. B. Badt, of Chicago.
16. "The Photography of Alternating Current Curves," by Dr. Edward L. Nichols, of Cornell University, Ithaca, N. Y.
17. "The Reversal of Polarity in Plating Dynamos;" and also on
18. "Dynamos for Continuous Current Circuits," by Prof. Harris J. Ryan, of Cornell University, Ithaca, N. Y.
19. "The Technical Education of the Electrical Engineer," by Prof. D. C. Jackson, of the University of Wisconsin, Madison, Wis.

Papers are also expected from Mr. H. Ward Leonard, Prof. Elihu Thomson and Prof. Geo. D. Shepardson, the subjects of which cannot be announced at present.

The convention rate of transportation at one and one-third the regular fare for the round trip, can be secured in case the attendance is sufficiently large to comply with rules of the Central Traffic Association. Members will be informed subsequently whether such arrangements can be perfected.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED APRIL 26, 1892.

Accumulators:—

Secondary Battery, I. L. Roberts. Reissue 11,238. Filed Jan. 28, 1892.

Employs an electrolyte of a salt of iron capable of forming an acid radical, and a non-porous electrolytic diaphragm interposed between the electrodes.

Alarms and Signals:—

Electric Railway Signal, C. E. Corporan, 473,614. Filed June 17, 1891.

A signal for steam railways which will automatically apprise an engineer of the approach of another train on the same track from either direction.

Thermostatic Fire Alarm, G. D. Mosher, 473,669. Filed Dec. 21, 1891.

Electric Signal for Railway Trains, L. Dunn, 473,832. Filed Nov. 30, 1891.

Conductors, Conduits and Insulators:

Covered Electric Wire, H. A. Reuter, 473,713. Filed July 25, 1891.

A covering consisting of parchmentized fibre, helically wound.

Coupling for Electric Wires, J. F. McElroy, 473,637. Filed Nov. 24, 1891.

A coupling designed especially for use in connecting the lighting and signaling wires on railway trains.

Distribution:—

Electric Switchboard, J. B. Mayer, 473,848. Filed May 11, 1891.

Has for its object to secure a more compact arrangement of parts, and greater security against burning out terminals.

Dynamos and Motors:—

Dynamo-Electric Machine, W. Decker, 473,547. Filed Nov. 25, 1891.

An armature for multipolar machines in which but two wires are connected in multiple at a time.

Commutator Connection for Electric Motors or Generators, C. G. Curtis, 473,567. Filed Aug. 26, 1891.

A riveted connection with the commutator bars presenting a large surface of contact and also permitting of easy disconnection if necessary.

Armature for Dynamo-Electric Machines or Motors, C. G. Curtis, 473,568. Filed Nov. 12, 1891.

Claim 1 follows:

An armature enclosed in a waterproof covering, that part of the covering in the path of the lines of force being of non-conducting material, and rigid caps protecting the ends of the armature.

Dynamo-Electric Machine, R. Eickemeyer, 473,618. Filed June 18, 1888.

Comprises a winding composed of a set of detachable counterpart coils each having a keystone form and having but one side in immediate contact with the face of the armature drum.

Dynamo-Electric Machine, R. Eickemeyer, 473,619. Filed Dec. 28, 1889.

An armature winding consisting of two or more mechanically united but independent coils, each longer on one side than the other, each centrally at its ends being in the form of a curved, flat web, and all but one of them folded inwardly near one side, and thence extended tangentially.

Galvanic and Thermo-Electric Batteries:—

Plunge-Battery, J. H. Howard, 473,463. Filed Dec. 1, 1890.

Employs shafts journaled in the casing near its opposite ends to which the carbon and zinc plates are attached respectively.

Lamps and Appurtenances:—

Alternating Current Arc Lamp, B. B. Ward, 473,536. Filed March 28, 1891.

Employs a carbon-supporting lever in connection with an alternating current lamp-magnet having its movable core connected loosely to the former, and a damper of the vibrations applied between the core and the lever.

Combined Gas and Electric Light Bracket, J. Fitzgerald, 473,661. Filed July 14, 1891.

Measurement:—

Electrical Measuring Instrument, E. Weston, 473,538. Filed Jan. 8, 1891.

An indicating device having a scale plate of translucent material in order that it may be illuminated and rendered visible at a considerable distance.

Electrical Measuring Instrument, E. Weston, 473,539. Filed Jan. 24, 1891.

A measuring instrument serving to convert the rectilinear movement of an armature into rotary movement of a needle over a scale.

Miscellaneous:—

Induction-Discharge Protector for Welding Apparatus, H. Lemp, 473,514. Filed Aug. 14, 1889.

Employs two electrodes connected respectively to the terminals of the primary coil and separated by a very narrow space containing air or insulating material.

Electric-Circuit Controlling Device, M. Thum, 473,594. Filed June 5, 1891.

A device by which the normal amount of current in a circuit may be maintained within certain limits or by which a signal is given whenever the current rises above or falls below the normal limit.

Circuit-Controlling Device, M. Thum, 473,595. Filed June 5, 1891.

A magnetic core having an electric contact portion, a helix surrounding the core and connected with the contact, and an armature having the contact adapted to bear upon that first mentioned and to be separated therefrom upon the movement of the armature toward the core.

Automatic Heat-Regulating Apparatus, C. F. Goodhue, 473,699. Filed May 29, 1891.

Electric Contact Protector, R. Varley, Jr., 473,717. Filed July 7, 1891.

Employs one electrode passing through an elastic shield.

Claim 1 follows:

Two electrodes, one of which is recessed in line of the other, in combination with an elastic septum through which one electrode passes and which sets tightly against the raised surface of the other electrode.

Automatic Transporter and Exploder for Explosives for Aiding Rain-Fall, L. L. Brown, 473,820. Filed Jan. 5, 1892.

Manufacture of Carbon Blocks, L. Hulin, 473,841. Filed Apr. 23, 1890.

A carbon conductor consisting of a number of specially prepared carbon plates fitted together and baked.

Process of Obtaining Metals from their Ores or Compounds, C. S. Bradley, 473,866. Filed Feb. 23, 1883.

Consists in combining a blow-pipe flame with the heating action of the current.

Electrically-Propelled Vehicle, F. Gardner, 473,871. Filed Aug. 31, 1891.

An electric tricycle.

Railways and Appliances:—

Electric Locomotive, S. H. Short. 473,674. Filed May 26, 1891.

Has for its object to prevent sudden shocks and jars to motors mounted directly upon the axles of vehicles.

Electric Locomotive, J. I. Conklin, 473,693. Filed Mar. 4, 1891.

Employs a series of motors combined with the main wheel constituting a main power transmitting device.

Switches and Cut-Outs:—

Circuit-Closer, C. H. Delano, 473,499. Filed Sept. 16, 1891.

Consists of a body of conducting material having a tubular passage for conducting-wires; an interior series of flexible strips and a conducting plate insulated from the conducting material, and having the wires connected with it.

Electric Switch, H. K. Hitchcock, 473,504. Filed Sept. 16, 1891.

Comprises a number of contacts for the purpose of connection between a circuit and any one of a number of dynamos.

Telephones and Apparatus:—

Two-Wire Telephone System, G. Taintor, 473,532. Filed May 9, 1890.

Has for its object to enable any station to call "Central" should either of the wires become broken.

THE DETROIT ELECTRICAL WORKS SYSTEM FOR JACKSONVILLE, ILL.

WE have received the following interesting communication from the Detroit Electrical Works with regard to another contract they have just secured:

The Jacksonville Railway Co., Jacksonville, Ill., W. S. Hook, president; B. F. Sibert, superintendent; after carefully investigating the merits of the different street railway systems, on January 6, 1892, decided to divide their order for motor equipments between the Detroit Electrical Works and the Thomson-Houston Company, and gave each an order for three 30 h. p. equipments, their object being to ascertain for themselves the comparative merits of the two systems for their benefit in placing future orders. The road was equipped and put into operation about March 1, 1892. May 2, the Detroit Electrical Works received an order for three additional 30 h. p. motor equipments. As it was given after both systems were put into operation, it is a victory for the Detroit Works, and supports their claim that their railway equipments will compare with any other manufactured. The equipments furnished by the Detroit Works under the original contract were their standard double reduction. Those furnished by the Thomson-Houston Co. were their latest W. P.

MADDEN'S IMPROVED STORAGE BATTERY.

MR. A. F. MADDEN has retired from Messrs. Lloyd & Payton, Ltd., and is now at work upon a radical departure in storage battery work. Mr. Madden's new cell closely resembles the Planté in principle, but by its method of manufacture it overcomes the tedious process of formation required by the latter, and forms the active material at once in the shape best adapted for heavy work. Mr. Madden claims that his new cell is entirely outside the claims of the Brush or Faure patents.

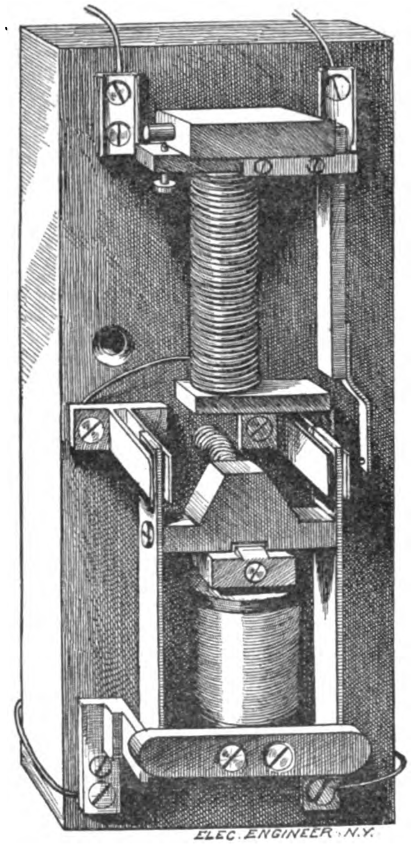
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Publicity and merit are the main supports of every successful business.

A NEW CUT-OUT OF THE INTERIOR CONDUIT CO.

This cut-out is designed to be placed in a circuit in a like manner to that in which a lead safety fuse is now connected.



New Cut-Out of The Interior Conduit Co.

It performs in all respects the functions of the ordinary fuse but with much greater accuracy. The instrument consists of a double-pole jack-knife switch, an adjustable relay for setting the cut-out at any load, and a knife resistance release magnet for opening the switch. The entire apparatus is mounted on a slate base with a glass-top mahogany cover, presenting a very neat appearance, besides being of very small size, namely 7½ x 3 inches.

The double-pole switch has a heavy spring tending to keep the switch open. The switch is kept closed by a catch attached to the armature of the release magnet. Placed above the switch is the relay wound with coarse wire which acts as an ammeter, the armature of which will close when energized by a sufficient amount of current, and makes a contact which completes a circuit through the release magnet. The armature of the latter being thereby attracted, the catch is removed and the switch flies open from the action of the heavy spring.

Supposing, for instance, the armature of the relay is adjusted so as just not to close when ten lamps, or whatever number it is set for, are in circuit. As soon as another lamp is added, the increased current will instantaneously cause the armature to close, when, the release magnet being energized, the switch immediately opens, both poles of the circuit being disconnected. Should it be attempted to close the switch while the overload is still on, the release magnet armature would instantaneously close and refuse to hold the switch down. Should a short-circuit take place, the action would be identically the same. One great advantage of the cut-out is its infallibility. Being once set to open at a certain current, it remains so, no matter how many times it is called into action.

It is as easy to apply as a safety fuse. The mains are connected to one side and the circuit to the other. It makes absolutely no difference to which end the mains are connected and to which end the circuit.

No other connections whatever are to be made, and the whole apparatus is self-contained. There will never be a chance of a three-light fuse carrying fifteen lights before fusing, as happens in many cases. If set for three lights it will always open when this number is increased. The device instantly commends itself to fire underwriters, insurance inspectors and all others who are interested in the continued progress made by the Interior Conduit and Insulation Co. or other concerns in the matter of properly safeguarding electrical conductors.

THE NEW WHITTINGHAM AUTOMATIC MOTOR STARTER.

The automatic switch, made by the Automatic Switch Co., of No. 8 Keyser Building, Baltimore, Md., has been eminently successful in connection with motors of the smaller horse powers when used by careful persons; but for the larger horse powers, and in general use, it has in some cases failed to work satisfactorily. The company has, therefore, for some time been experimenting with the object of eliminating the weaknesses of the automatic switch, and have now introduced the new Whittingham automatic motor starter, the operation of which will be readily understood by referring to the accompanying illustrations.

As will be seen, Fig. 1 is an exterior view of the device, while Fig. 2 is a diagram of the working mechanism. The solenoid magnet furnishes the power for operating the heavy contact bar which slides up over the resistance plates, and acts against the control of the dash-pot at the bottom of the starting box, thus making a gradual movement over each successive resistance plate.

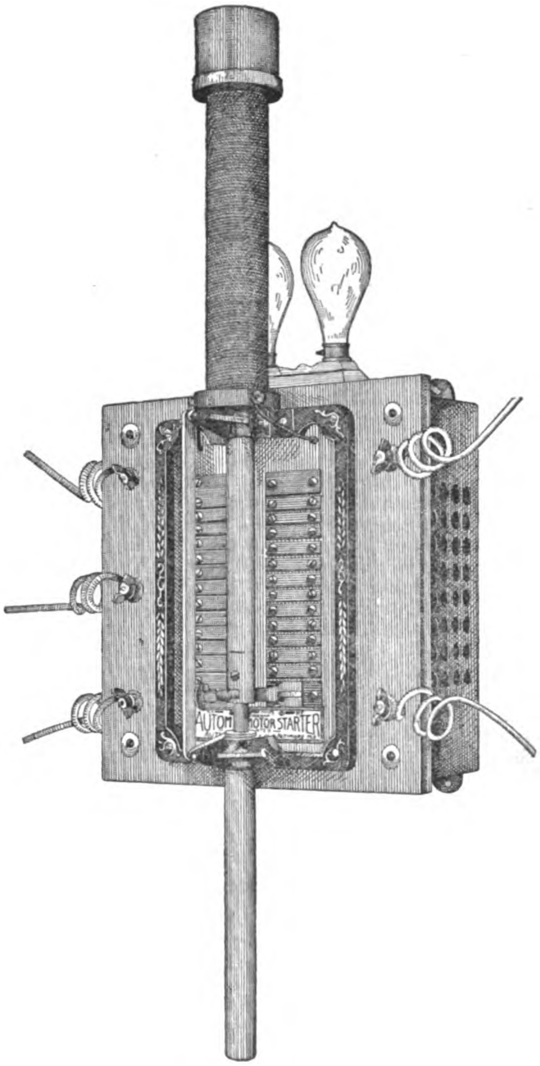


Fig. 1.—New Whittingham Automatic Motor Starter.

When the top contact is reached, the power of the magnet is automatically weakened, and only enough magnetism developed to hold the contact bar firmly in place. The energy consumed in the magnet when the bar is in its final position with the motor running, is only about forty watts. When the current is cut off, the magnetism ceases, and the contact bar falls to its original position at the bottom of the resistance plates, ready to start the motor again when the current is turned on.

The design is entirely new and the workmanship excellent. The box is fireproof, nothing but slate and metal being used in its construction, while the resistance blocks are of sufficient number to avoid any unsteadiness in starting. A double-pole switch is furnished with each starter. The two are entirely separate, however, and the former may be placed at any convenient point.

In elevator, pumping or other work of intermittent character, this automatic motor starter will be found of great service, since it is only necessary to arrange for the opening and closing of a simple switch.

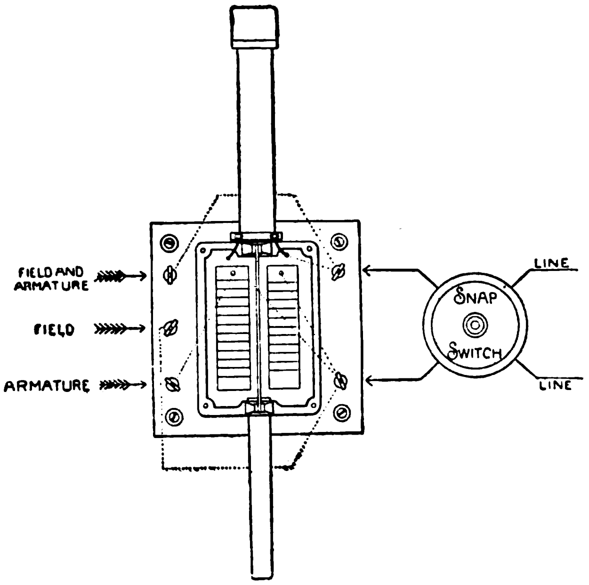

FIG. 2.—NEW WHITTINGHAM AUTOMATIC MOTOR STARTER.

ACTIVITY OF THE BALL & WOOD CO.

THE Ball & Wood Company ever since the shipment of their first Improved Ball high-speed engine in October last have been running twenty-four hours each day to keep up with their orders, and now have between twenty and thirty engines on the floor under construction, all contracted for. Important additions to their works are under contemplation. Among their recent shipments are the following: Two 300 h. p. cross-compound engines for the Brush Electric Co, Cleveland, Ohio; two 125 h. p. engines for the Yonkers Street Railway Co., Yonkers, N. Y.; one 100 h. p. engine for the Pennsylvania Railroad Co., of Baltimore, Md.; one 150 h. p. engine for the Tide Water Oil Co., Bayonne, N. J.; two 300 cross-compound engines for the Sauquoit Silk Manufacturing Co., Scranton, Pa.; one 300 h. p. cross-compound engine for the Edison Electric Illuminating Co., Paterson, N. J.; three 150 h. p. standard engines for the Edison Electric Illuminating Co., Paterson, N. J.; one 150 h. p. engine for the State House, Trenton, N. J.; one 100 h. p. engine for the Meriden Electric Light Co., Meriden, Conn.; two 80 h. p. engines for the Four Seasons' Hotel, Cumberland Gap, Tenn.; one 150 h. p. engine for the Laconia Car Co., Laconia, N. H.; two 150 h. p. engines for the Chicago Arc Light & Power Co., Chicago, Ill.; one 100 h. p. engine for Sulzer Brothers, Winterthur, Switzerland; one 60 h. p. engine for the U. S. Navy Yard, Brooklyn, N. Y.

A "SOUVENIR" OF BRUSH ISOLATED PLANTS.

THE BRUSH ELECTRIC Co., of Cleveland, has issued a sumptuous brochure, which contains a series of admirable illustrations and descriptions of six complete isolated incandescent plants which it has installed in so many of the largest and finest office buildings in the world, situate in Kansas City, Omaha, Minneapolis, St. Paul, Montreal and New York City. The text has been carefully compiled by Mr. Will. H. White and includes a detailed account of the new Brush incandescent machine. Not only are exterior and interior views given of the buildings, which are those of the New York Life Insurance Co., but there are a large number of views of the plants that light them. There also appear illustrated descriptions of the U. S. cruiser "Boston" and her plant, and of the Grand Hotel, Yokohama, and the Hotel Fuji, Japan. The book is a large quarto and comes from the press of the Matthews-Northrup Co. It has a richly illuminated cover fastened with silken cord.

NEW ENGLAND NOTES.

THE WEST END STREET RAILWAY COMPANY, of Boston, having found that the present 25-foot cars are too large for economical working during the light traffic hours, and too long for the faithful collection of fares when crowded, have decided to try 20-foot cars in future. The 25-foot cars are also very heavy and pound the rails very hard, and while they have been acknowledged to be a success as a convenient and easy riding car, it has been determined to try a car somewhat shorter. The West End Company are also busy preparing a number of four-wheel trucks of a new design for use on the 18-foot open summer cars. These trucks will most probably be equipped with single motors of 25 h. p.

THE JARVIS ENGINEERING COMPANY, of Boston, have secured the agency for New England of the American feed-water heater, manufactured by the Whitlock Pipe Coil Company, of Elmwood, Conn. This heater is the result of over 14 years' experience in the manufacture of various styles of feed-water heaters, and is constructed of one or more coils of the best seamless drawn copper tubing, incased by an iron shell with brass fittings. The heater is first-class in every respect, and possesses a number of advantageous features distinctly its own. Electrical engineers would do well to investigate its merits as early as possible.

THE WEST END STREET RAILWAY COMPANY, of Boston, have sent to the aldermen a copy of the report of the commission appointed by the company in the matter of electric car fenders, and called attention to the fact that the commission recommend the company to put on 50 of the pattern known in general as the "Cleveland fender," for trial. These fenders, Mr. Whitney states, were ordered at once, and, if they prove satisfactory, will be applied to the cars as soon as possible. The commission has not yet been discharged, as other experiments are being tried.

THE GOULD PACKING COMPANY, of East Cambridge, manufacturers of the famous Gould packing for steam engines, continue to do a good business, and are daily in receipt of orders from engineers for their goods. This packing is largely imitated and engineers would do well to send in their orders direct, or else to some thoroughly reliable supply house, as there are large quantities of so-called Gould packing on the market which never was manufactured at East Cambridge and which is of a very inferior quality.

THE BERLIN IRON BRIDGE COMPANY have received the contract for the new rolling-mill which the Waterbury Brass Company, of Waterbury, Conn., will build to replace the one lately destroyed by fire. It is said that this will be the finest rolling-mill in the Naugatuck Valley, being 150 feet in width by 350 feet in length, with brick side walls and iron roof trusses covered with the Berlin Bridge Company's patent anti-condensation corrugated iron roof covering. The building will be absolutely fireproof.

THE BROOKLINE GAS LIGHT COMPANY, of Brookline, held a reception at their new station on April 21st, under the auspices of the president and directors of the company, when an opportunity was afforded the visitors of thoroughly inspecting their new plant, recently described in these columns. About 200 guests were present, and were cordially received and shown through the many interesting departments of the works, after which a collation was served.

THE MASSACHUSETTS ELECTRICAL ENGINEERS' AND MECHANICS' ASSOCIATION held their third anniversary of their establishment, last Tuesday, the 26th of April, at the Association's headquarters, No. 3 Boylston Place, Boston. Dinner was served, after which an address was made by the president of the organization. Among the invited guests were Inspector of Wires B. S. Flanders, Deputy Inspector William Godfrey, Prof. Gilley and E. A. Bicknell.

THE VAN DEPOELE MEMORIAL ASSOCIATION has recently had its first annual dinner to honor the memory of C. J. Van Depoele.

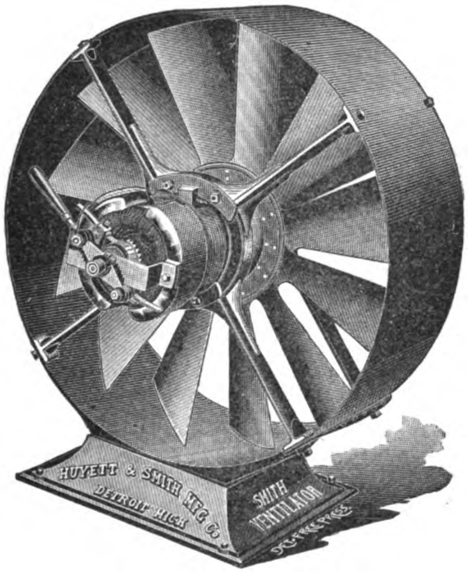
PHILADELPHIA NOTES.

THE WEST END ELECTRIC CO., although not a year in existence, have recently made several additions to their plant at Thirty-first street and Girard avenue. Their present capacity is five 50-light Thomson-Houston arc dynamos, two 1,300 and one 650-light Thomson-Houston alternating dynamos. Mr. A. J. Martin, their superintendent, says that the Bishop cables which are used throughout the plant show an average insulation of 200 megohms per mile with transformers connected, and have not given the slightest trouble.

MR. L. F. RONDINELLA, electrical, mechanical and civil engineer, has opened an office at 705 Chestnut street, where he will conduct the business of his profession. Mr. Rondinella is well known among the electrical fraternity, having been a professor at the Central Manual Training High School for several years and has taken a lively interest in electrical and other scientific matters at the Electrical Section of the Franklin Institute, where he acts in the capacity of secretary and treasurer.

THE HUYETT & SMITH ELECTRIC VENTILATING FAN.

We illustrate on this page a very compact and efficient ventilating fan which has recently been brought out by the Huyett & Smith Manufacturing Co. of Detroit, Mich. As will be seen from the illustration the motor is snugly carried by a spider and on the same axle as the fan itself. There is thus practically but one moving part, and the motor by being thus centered does not obstruct the process of ventilation. The circular form of the motor gives a very strong magnetic field as well as secures economy of weight and space. The motors are so wound as to require no external resistances etc., and the simple switch by increasing or lessening the speed governs the amount of air that is delivered. The motors run quite noiselessly and are free from sparking at the commutator. They are built in various sizes and will furnish according to their size from 6,000 to 40,000 cubic feet of air per minute at normal speed. The whole is neatly mounted on a strong base and can be quickly set up.

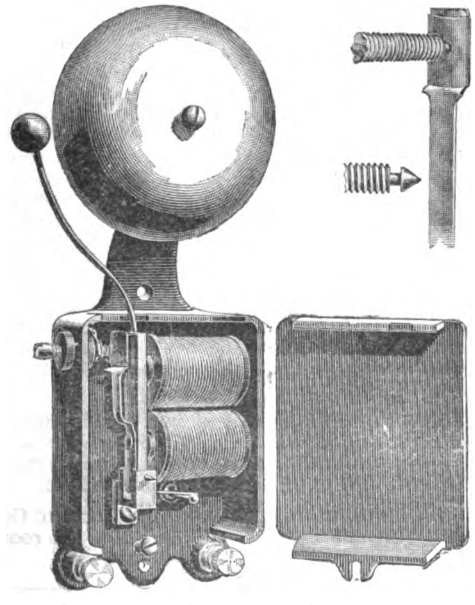


HUYETT & SMITH MFG. Co.
DETROIT MICH.
SMITH VENTILATOR

Huyett & Smith Electric Ventilating Fan.

J. JONES & SON'S ANTI-DUST BELL.

The above company, located at 602 West 22d street, New York, have recently placed on the market a bell which is as much protected from dust as any ever shown. Besides this, the make-and-break apparatus is further protected, as will be seen by the cut herewith. The contact points are enclosed in rubber so that not a particle of dust may enter. This makes a very clean contact and one that, with the perfect points used, will practically last forever. When once the bell is placed and the cover attached, there is no reason why it should ever be opened. A device for regulating the contact is placed outside the box.

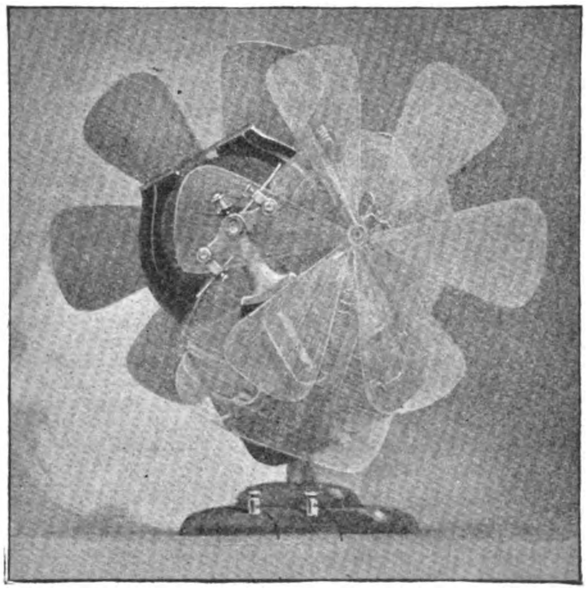


J. Jones & Son's Anti-Dust Bell.

THE CROCKER-WHEELER PIVOTED FAN MOTOR.

Those who during the past summers have enjoyed the artificial breeze stirred up by an electric fan outfit, and the better ventilation which results therefrom, will thoroughly appreciate the merits of this recent product of the Crocker-Wheeler Electric Company, New York. The illustration almost explains itself.

The pivoted fan motor is mounted upon an ornamental base of dark-red wood and swings slowly around the circle upon a pivot, throwing the breeze to every corner and part of the room. It will be readily understood that the ventilation is therefore complete, while the motion imparted to the atmosphere more closely resembles the cooling breezes of nature than the steady blast from a stationary fan. The pivoted fan motor is equipped with the Crocker-Wheeler variable speed switch, thus giving either a gentle zephyr or a strong breeze, as may be desired. These outfits are furnished, $\frac{1}{12}$ h. p., 115 volts, and $\frac{1}{6}$ h. p., 115, 230 or 500 volts, with self-oiling bearings. The $\frac{1}{6}$ h. p. 500-volt motor has only one speed.



Crocker-Wheeler Pivoted Fan Motor.

RAILWAY WORK IN OHIO.

The East Liverpool and Wellsville Electric Railway, which was completed last December, exactly three months from the day ground was first broken, is one of the most successful ever installed, and the company have already found it necessary to double the equipment. The J. G. Brill Company are just completing eight fine open cars, for which the Short Electric Railway Company of Cleveland, Ohio, will furnish 16 20 h. p. single-reduction motors and two additional 133 h. p. generators, and Messrs. E. H. Jones & Co., of Cleveland, who put in the first steam plant, are also doubling their part of the equipment.

A number of persons interested in the Cable Railway Company have recently secured franchises for an electric railway in Fort Wayne, Ind., to be called the "Fort Wayne Electric R. R. Co." The order for the equipment has been placed by Robison Bros. with the Short Electric Railway Company. It consists of the following apparatus: 32 car equipments complete, comprising 64 20 h. p. single reduction Short motors and 10 miles of overhead construction. Shipment of apparatus is already begun, and from the vigorous manner in which the Robisons are pushing the construction work, it is expected that the road will be completed and in operation by the 1st of June.

Fitch Battery and Electric Co.—This company, in mentioning that its "Perfect" battery is always clean, has a low internal resistance, has a constant E. M. F., is slow to polarize and quick to recuperate,—calls attention to its "Perfect Battery Excitant," which they furnish for all cells using carbon and zinc with sal ammoniac. This excitant is designed to supersede sal ammoniac; and a trial package costs so little that it would seem that at least an experiment would be in order by battery users.

PHILADELPHIA NOTES.

Mr. George Weston, of W. H. Weston & Co., switch manufacturers, met with a severe accident last week while operating a milling machine. The sleeve of his left arm became entangled with the metal saw which while in motion drew his arm through the machine, causing a painful wound that will disable him for several weeks.

Mr. Thomas Spencer, formerly chief electrician for the North American Construction Co., of Pittsburgh, Pa., has accepted a position as electrical and mechanical engineer for the Star Electrix Co., of this city. Mr. Spencer is widely known in both England and this country as a consulting electrical engineer.

In Partrick & Carter Co.'s advertisement this week will be found an illustration of their patent needle annunciator for house use. The firm's catalogue shows many styles of cases in which they make this annunciator and a copy should be in the hands of the trade everywhere.

Vallee Bros. & Co. have been appointed sole agents for Philadelphia and vicinity for the well-known Paiste switches and "K. W." cut-outs now manufactured by the Bryant Electric Co., Bridgeport, Conn.

The La Roche Electric Works are very busy just at present. They have contracts on hand to equip three central stations and nine isolated plants in various parts of the country.

The Star Electrix Co. are contracting with outside parties to make electrical supplies in addition to the manufacturing of their specialties.

A. J. **Martin** and Edward R. Grier have been appointed special agents to collect statistics of electrical industries in Philadelphia.

Mr. Arthur L. Bosley has resigned his position as president and manager of the Pennsylvania Electric Engineering Co.

WESTERN NOTES.

The Minneapolis Street Railway Company's new power house will be equipped with ten 300 h. p. Westinghouse engines running ten Thomson-Houston generators of equal power. The engines are compound, with cylinders 16 and 27 inches in diameter and 16-inch stroke. Each engine is connected to its dynamo by a 24-inch leather belt running from an 82-inch pulley on the engine to a 36-inch pulley on the dynamo. This plant will be 3,000 h. p. grouped in a space 87 feet by 73. The boiler-room will occupy an equal area, and will contain seven Sterling high pressure water-tube boilers, with a capacity of 287 h. p. each. The fuel will be crude oil, pumped from tanks as needed. Water will be supplied from an artesian well, which is now drilled to a depth of 575 feet.

Heine Safety Boiler Co.—We are in receipt from the Heine Safety Boiler Co., of St. Louis, of a circular presenting a record of two comparative tests between their boilers and those of the Babcock & Wilcox Co., admitting defeat in one trial and claiming a decisive victory in the other. The case is presented with considerable pressure of steam, and forms an interesting addition to one of the most important techincal controversies of the year. We are not buying boilers ourselves, but a good many of our readers are, and for such this kind of reading must have no small charm, affecting the pocketbook very closely and deeply as it does.

The Great Western Electric Supply Co. have recently largely increased their facilities and have taken the entire second floor of the Springer Building to meet the requirements of their growing trade. They have fitted up an exceedingly handsome show-room and extensive suite of offices adjoining. This new departure is in line with the progressive policy of the company, who are now doing a very large amount of manufacturing of their own goods and have equipped their extensive factory with all the latest and most approved tools for their special line of work.

The Electric Appliance Company report several very large orders for swinging ball lightning arresters. They have furnished a complete equipment of these valuable devices to a number of the largest plants in the Western country. Station managers generally are beginning to realize that lightning arresters are as necessary as insurance on their plants, and the swinging ball lightning arrester is filling the demand for an instrument that can be put up once for all and afterwards be depended upon to be there and do its work without further attention.

Rodolphus Fuller, electrical and mechanical engineer and supt. Fontaine Crossing Co., Detroit, Mich., was a caller at the Western office of The Electrical Engineer last week. Mr. R. Fuller is supervising the putting in of a number of the Fontaine railroad crossings on the Chicago and Northern Pacific R. R. here.

Mr. F. J. Pearson, electrical engineer and expert, of Kearney, Neb., is desirous of representing a few Eastern electrical companies in his part of the country. Mr. Pearson's wide practical experience in electrical work and electricity will be of especial value to him in the commercial field.

Mr. H. W. Gilman, general manager of the Great Western Electric Supply Co., recently returned from a business trip East, on which he secured a number of large orders for general electrical supplies and the various specialties manufactured by the company. The Great Western Electric Supply Co. will shortly issue a very complete and handsome catalogue of their house goods. They report that they are exceedingly busy in the manufacturing of arc lamps for incandescent circuits and are now some 200 lamps behind with their orders, but with their recently increased facilities will very soon catch up. They state that their Sun arc lamps are giving very general satisfaction, and that repeat orders are numerous.

Mr. J. R. Burdick, traveling representative for the H. W. Johns Manufacturing Company, was a caller at the Western office of The Electrical Engineer last week and was accompanied by Mr. R. B. Pierpont, agent and manager of their branch at No. 240 Randolph street, Chicago. Mr. Burdick is representing the company in their specialties in both steam railroads and electrical work from the Atlantic to the Pacific. His acquaintance with electrical and railroad interests throughout the country is one enjoyed by few other men.

Mr. J. H. Cooke, who for the past three years has been the secretary and treasurer of the Sunbeam Incandescent Lamp Co. since its organization, has resigned and taken charge of the interests of the Buckeye Electric Co. of Cleveland, Ohio, for Chicago and vicinity, with headquarters at No. 437 the Rookery, Perhaps no man is better known in the incandescent lamp business throughout the West than Mr. Cooke, and the Buckeye Co. are to be congratulated on securing his services to push their well-known incandescent lamps.

The Star Electric Co. has been formed at Des Moines, Ia., with Mr. F. M. Pierce, as manager. It will carry on business as an electric supply and construction house, and will carry a stock of electrical goods. Its headquarters will be in the Marquardt Building on Locust street.

Clark & Marshall have moved from their old quarters to larger ones at 413 the Rookery, Chicago. They are dealers in electric specialties and handle electric fixtures, incandescent lamps, office electric fan motors, etc.

The Chas. Munson Belting Co., through their Mr. Morgan, have furnished the National Electric Manufacturing Co. of Eau Claire, Wis., with one 36-inch double and several others of various sizes for their new factory.

Universal Radial Drill Co.—The above company in getting out their calendar for May show a 30-inch heavy engine lathe. The usual child's face and instructions concerning the lathe accompany the calendar.

Mr. George Cutter has moved his shop to 315 South Canal street, and is just beginning to make things hum in his new and larger quarters. His specialties go as rapidly as ever.

Mr. F. H. Prentiss, president, and Mr. C. H. Rockwell, treasurer of the Buckeye Electric Co., were welcome visitors to Chicago last week.

NEW YORK NOTES.

The Malone, N. Y., Electric Light and Power Co., and the Malone Gas Co. have consolidated with a capital stock of $50,000, the new company being styled the Malone Light, Heat, Power and Coal Co. The company is now building a new electric light station, and will install a Hamilton-Corliss engine costing $6,000. The electric equipment will consist of two 750-light Slattery alternators and complete accessories, all of which were sold to the company by Mr. W. J. Morrison, New York State agent of the Fort Wayne Electric Co. The officers of the new company are as follows: N. W. Porter, president; F. E. Kilburn, vice-president; H. H. Porter, secretary and treasurer; J. H. Findlay, general manager. The company expects to spend $15,000 on the plant, and will shortly put in a Wood 50 arc light machine. When finished the plant will be one of the best designed of its size in this country.

The Standard Paint Co. enjoy a large trade abroad as well as at home for their compounds and paints for electrical purposes, and not long since were in receipt through their advertisement in The Electrical Engineer of an order from Finland.

The Thomson-Houston International Electric Co. has removed its New York offices from 115 Broadway to room No. 11, eighth floor, 44 Broad street—the Edison Building.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XIII. MAY 18, 1892. No. 211.

ARGUMENTS AND MODELS IN THE EDISON "FEEDER" AND "MAIN" CASE.

THE celebrated Edison "Feeder" and "Main" case, of which the electrical public has heard a good deal from time to time, was last week, after more than five and a half years of active preparation, brought up for argument before Judge Green at Trenton, in the United States Court for the Southern District of New Jersey. In its bearing on the incandescent lighting industry, this suit is considered second only to the "Filament" case first argued before Judge Wallace, in New York City, last summer, in which a decision was granted upholding the Edison patent.

In 1886 an electric light plant was installed in the city of Trenton by the firm of Westinghouse, Church, Kerr & Company. The Edison Electric Light Company believed this installation infringed their patent of Mr. Edison of September 19, 1882, No. 264,642. on the use of *feeders* in a system of distribution. This patent states that a feeder system is one comprising two distinct parts, each of which has an independent function. One part, that to which the lamps are connected, is so calculated that the greatest loss or "drop" in pressure will be so slight as to be negligible as far as it affects the relative candle power of the lamps in different portions of the district lighted ; this is the "consumption circuit." The other part is that which connects the consumption circuit with the generating station; it has no lamps on it, and the drop in pressure to be found therein does not affect the relative candle power of the lamps on the consumption circuit; this is the "feeder."

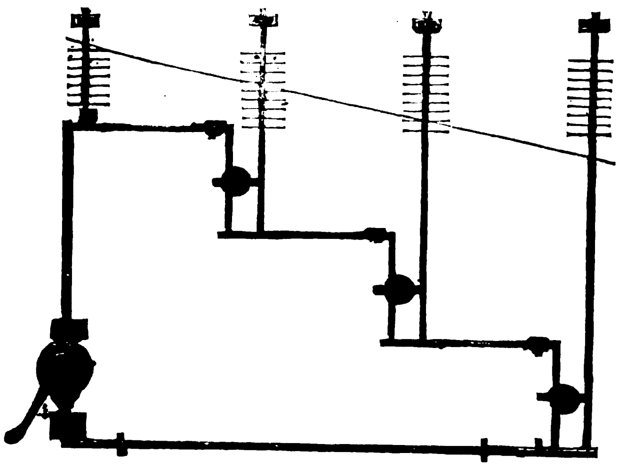


FIG. 1.—WATER ANALOGUE SHOWING SERIES SYSTEM OF DISTRIBUTION.

Suit was brought, and after five and a half years of bitter fighting it has reached the long-desired stage of argument.

A case of this sort is of a very technical nature, and when it is appreciated that within a period of one or two days sufficient instruction must be given to enable a judge to understand fully the meaning conveyed by the terms "volts," "amperes," "drop," "electromotive force," "multiple arc," "series," "potential," "candle power," "B. W. G." "ohm," and the thousand and one other things which are necessary to a comprehension of the subject, it will be seen that the lawyers have an unenviable task before them.

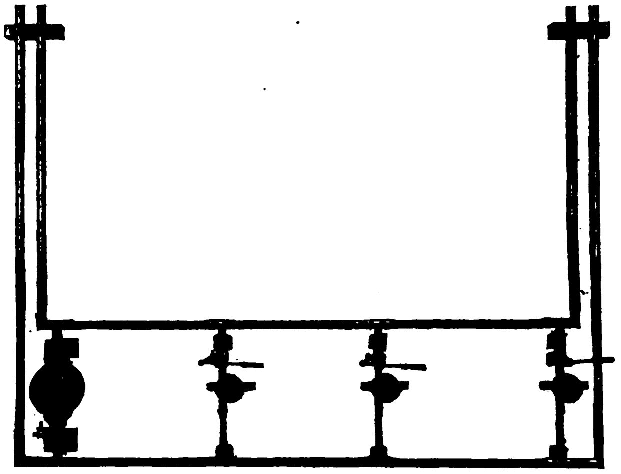

FIG. 2.—WATER ANALOGUE SHOWING MULTIPLE ARC SYSTEM OF DISTRIBUTION.

To save time, to make a few words accomplish as much as many, to illustrate each step of the argument as it is unrolled, has necessitated the preparation of quite a collection of physical apparatus. No care or expense has been spared in preparing such material as will conduct the judicial mind, by easy yet rapid stages, to a point where it will be competent to form an opinion.

To give a clear idea as to what is shown, the various exhibits will be described in detail :

1. *Bird's Eye View of Defendant's Pole Line.*—On a table ten feet long by four in width is a map of that portion of the city of Trenton which was, in 1886, covered by the pole line of the defendant. On this map, which also shows the premises supplied with current from the mains, are erected little brass poles, 3½ inches in height, supplied with cross-arms and insulators as originally used. From a structure representing the cupola of the central station, emanate the four sets of feeding conductors which run to those portions of the town where they join the network of mains. The feeders are what are termed "split feeders," that is, instead of using one large-sized conductor for each polarity, several smaller ones are connected up together, to get the same carrying capacity. The conductors of the model are of red, black and blue silk, a color for each side of the three-wire system. The mains, which in the origina

installation were No. 00 wire, are shown in the exhibit by colored strands of very heavy corded silk. This model is designed to clearly indicate to the Court just what conductors were run and how, and their relative bearing towards one another.

2. *The Water Analogues.*—The patent in suit refers to translating devices connected in multiple arc, as contrasted with those connected in series. Electrical text-books have for years made use of the water-wheel and a series of pipes as an excellent illustration (on paper) of the characteristics of the two methods. It remained for this trial, however, to first show the *actual* working of water-wheels in series and in multiple arc. The illustrations, Figs. 1 and 2, show these two models. As will be seen, Fig. 1 shows a closed system of glass tubing, with three water-wheels and a rotary pump included in its circuit. The tube system is filled with a colored liquid. Pressure tubes rise from the various levels of the system. When the apparatus is at rest the liquid in all the tubes remains at a uniform height. By turning the pump crank the "difference of potential" is at once shown by the variation in the water-levels in the various pressure tubes, as well as by the revolution of the little turbines. If the main line is closed so as to prevent the water from moving, all the turbines stop. This is the series arrangement.

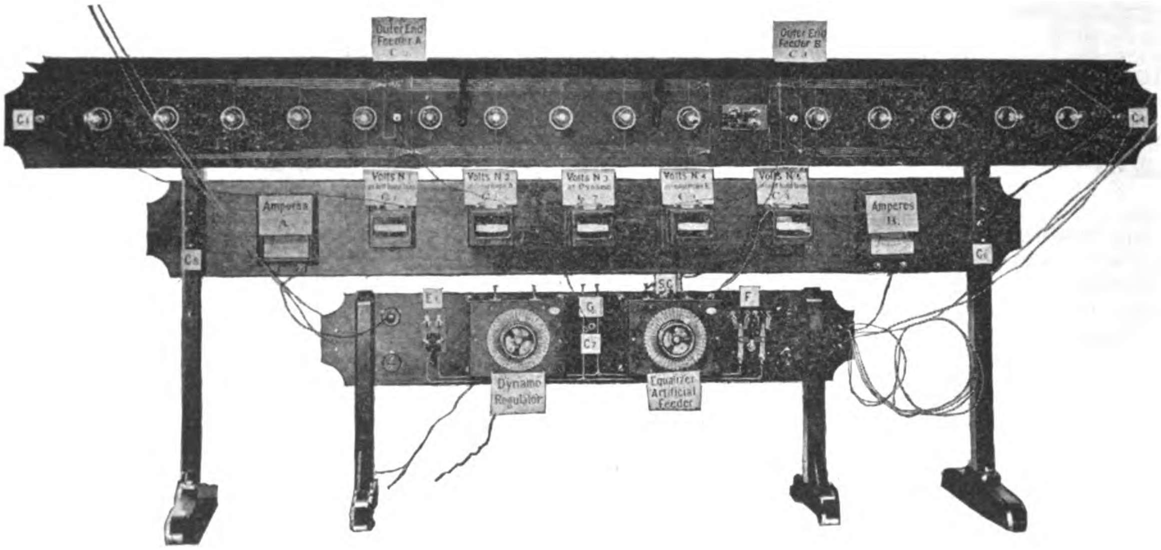

FIG. 3.—MODEL SHOWING COMPLETE FEEDER SYSTEM OF DISTRIBUTION.

An entirely different arrangement is shown in Fig. 2, which illustrates the multiple-arc method of connecting translating devices, such as water-wheels, lamps, motors, or converters. At the left is the pump or source of power, with two pressure tubes to indicate the difference of potential at this point. From the pump extend horizontally two tubes, to which are connected at intervals three turbine wheels, such as are shown in Fig. 1. The horizontal tubes terminate at the right in another pair of pressure tubes. All the valves in the turbine services being closed, the pump crank is turned so as to get a certain difference of potential between the upper (+) and the lower (—) horizontal tubes. The pressure-tubes at the extreme right will also show a difference, but not so great a one as the others, due to the *resistance* of the horizontal mains. Each wheel can be turned on or off independently of the others and, of course, takes its own individual portion of water, which does not flow through the other wheels, as in the case of the series model.

3. *Illustrative Model of a Feeder System.*—To give to the Court a visual demonstration of the electrical characteristics of a feeder system the apparatus shown in Fig. 3 has been devised.

The diagrammatic connections of this apparatus are clearly shown in Fig. 4, which is taken from one of the exhibits entered in the case. As will be seen, the consumption circuit of fifteen lamps is divided into two parts which can be thrown together when desired. Each part is supplied by a different feeder. The current through each feeder is measured on an amperemeter, while the five voltmeters can be connected to as many points of the system so as to obtain simultaneous readings from the dynamo, the ends of the two feeders, and the ends of the consumption circuits. If desirable, the pressure half way down the feeder can also be indicated. This arrangement permits of the demonstration of the various phenomena which are found in feeder systems. An "artificial feeder" or short feeder connecting the consumption circuit directly to the dynamo "bus-bars," can also be employed to show what distortions may result from an unintelligent disposition of conductors. The generator supplying the current for these demonstrations is run in connection with a very neat plant, which was erected for the purpose in a building some 300 feet from the court-room. Of course, the generator must be under the control of the electrician at the court-house, so the plant is arranged as follows: An upright boiler supplies steam to a small marine engine and dynamo (coupled direct) which in turn furnish the power to run a 3 h. p. differentially-wound Sprague motor; the motor is belted to a 15 K. W. dynamo, whose shunt field circuit runs to a hand regulator on the model before the Court. A belt circuit serves as a means of communication between the two portions of the plant.

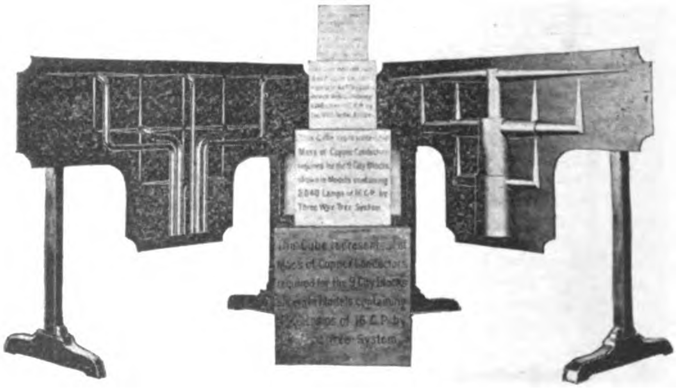

FIG. 5.—MODELS SHOWING ECONOMY OF FEEDER SYSTEM.

4. *Models Showing Economy in Use of Feeder System.*—

As a basis of comparison between the relative economy of the "feeder" system and the "tree" system of distribution, a district of 36 city blocks, in the form of a square, was assumed. The central station was placed at the centre of the square; each block has 16 consumers who used 15 lamps each; conductors were run from the station to supply each of the four quarters of the district with light; in the one case, feeders were employed; in the other case a straight "tree" system was used. Several models have been made to show a comparison between the two systems, and Fig. 5 shows one of a group of these. To the right is shown a model which represents, to scale, the amount of copper in one polarity required to supply one of the quarter districts by the "tree" system; to the left is a model on the same scale, representing the amount of copper required to supply the same district by the "feeder" system; between these models are shown four cubes which represent one one-hundredth of the actual amount of copper required for the quarter-district by the two-wire tree system, three-wire tree system, two-wire feeder system, and three-wire feeder system, in regular order from the floor; the linear dimensions of the cubes, in the same order, are as follows: 29¼ inches, 21 inches, 15⅘ inches and 11½ inches. The total weight of copper for the four quarter-districts by the tree system is 803,250 pounds; the weight when the feeder system is used is 128,789 pounds. This is a reduction from $23.24 per lamp to $3.72 per lamp.

FIG. 4.—DIAGRAM OF CONNECTIONS FOR FEEDER SYSTEM OF DISTRIBUTION.

Another means of showing graphically the enormous saving obtainable by the use of the feeder system over its predecessor in the art, is exhibited in another set of models. On a board two feet high and eleven feet long is shown the feeder-distribution required for three of the block-faces shown in the models of Fig. 5. Both the feeders and mains are stranded, the conductors being laid side by side; No. 8 wire is employed. Contrasted with this model is one mounted on a board nine feet high and eleven feet long, in which the same lighting is done by the tree system. The relative sizes of the conductors required is shown by taking six No. 8 wires and laying them close together as the conductor for each house. This is done as there is required just six times the copper per house, in the mains by the tree system, as in the feeder system. The contrast can be appreciated by the statement that in the one case 96 No. 8 wires are laid side by side, and in the other case, 576 No. 8 wires are necessary.

In addition to the models enumerated, there is a large rack on which a dozen immense charts on shade rollers are mounted. As will be seen, the judges have opportunities here for getting an insight into electrical subjects which may probably never be vouchsafed to them again.

STORAGE BATTERIES IN CENTRAL STATIONS IN PARIS.

BY

Henry A. Currie

In the editorial in The Electrical Engineer of April 27, on the subject of "Storage Batteries in Central Station Works," mention is made of Paris among other cities, as being one where accumulators are largely in use. As I have given special attention to this particular subject and had occasion last autumn to visit Paris twice with a view to inspecting the several storage battery stations in that city, a few particulars may be of interest. I was greatly surprised to find how comparatively little appeared to be known outside of Paris itself of the very elaborate and extensive scale upon which accumulators are in use there. The type principally in use in Paris is that supplied by the Société Anonyme pour le Travail Electrique des Metaux, from their extensive works at St. Ouen on the Seine. The principle of manufacture adopted by this company is that of casting chloride of lead combined with a small proportion of chloride of zinc with tablets (pastilles). These tablets are then placed in a special mold and ordinary lead cast around them, thus forming a uniformplate. As the process is precisely similar to that adopted by the Electric Storage Battery Co. at Gloucester, N. J., and described in this journal some time ago,[1] it is not necessary to repeat it. The principal feature of the plates as manufactured in France is their size. The plates in all the electric light stations in Paris weigh about 20 kilos (44 lbs.) each. The cells containing from 15 to 25 of these plates are naturally very large. At the time of my last visit (November of last year) the majority of the cells in use contained 25 plates weighing 20 kilos each, making total weight of plates per cell about half a ton. Cells containing plates weighing in all one ton per cell were at that time being prepared. In the city of Paris alone there were then over 75,000 lamps dependent upon these accumulators. The Popp system alone has 16 distributing stations installed with the half-ton cells from which they supply current for over 25,000 lamps. These distributing stations are charged in series of three or more at a time from one central power station. A notable feature of this system is the fact that from four o'clock in the afternoon until the following morning no engines and dynamos are running. That is to say, during the time of heaviest load the lamps are entirely dependent upon the accumulators. At each distributing station there is one attendant taking readings day and night. These readings are all sent in to the head office where they are summarized and tabulated, thus affording an exact record of the output, input and efficiency of each station. To maintain the E. M. F. constant, the ordinary system of auxiliary cells is adopted with however the special feature that instead of using any automatic device the time at which each auxiliary cell is put in and out out of the circuit is registered together with its mean rate of discharge while in use. The total output of each additional cell is thus registered. When charging, each of these cells is permitted to receive the amount in amperes of its discharge, plus a certain surplus to cover loss. This surplus I was given to understand averages about ten per cent. over and above the output.

The manufacturers guarantee the maintenance of the batteries at a fixed cost to the installation companies. This cost is based upon a certain per cent. of first cost and output of the cells. They also guarantee a total efficiency of not less than 63 per cent. under all circumstances. In the event of the efficiency of any station proving less than 63 per cent. certain allowances are made by the manufacturing company to the installation company; and if above 63 per cent. certain allowances are made by the installation company to the manufacturing company. The deductions or allowances are proportional to the amounts above or below the guarantee. Apparently the efficiency has always exceeded the standard of guarantee, showing averages of from 72 to 85 per cent. in the several stations.

In addition to the 25,000 lamps supplied from accumulators under the Popp system there were in Paris numerous isolated plants as well as various electric light companies all using the same type of cell, showing a total in lamp capacity of over 75,000 lamps. I believe at the present time this number has been increased to over 100,000 lamps.

The rapid pace at which the business is extending is of itself a proof of its practical and financial success. Not only are plants already installed being extensively increased but a large number of new installations are being put up in various parts of France, the accumulators being supplied from the works at St. Ouen. A visit to these works was of special interest. The output last autumn averaged about five tons of plates a day. This had been the average apparently during last year. Although plates of various sizes are manufactured, the majority were twenty-kilo plates. It is to the fact of using these large plates and large cells, together with the high efficiency and durability of this special type, that their success is attributed. At certain tests made on behalf of the French Government at the navy trials at Toulon, an efficiency of 90 per cent. was attained with this type. The manufactory at St. Ouen is laid out and systematized with the same precision as the installations. Having been afforded special facilities for investigating every detail of manufacture I was enabled to appreciate what a profitable business is possible both in the manufacture of storage batteries as well as in the supply of current from large installations of the same. In Paris the manufacturing success is of course due to, and dependent upon, a constant market. In this case the market has been made and maintained principally by the companies supplying light. The success of the latter means success of the former. The success of the supply installation companies appears to be largely due to their adoption of the principle of doing everything on a sufficiently extensive scale whereby a proper system of supervision and control is insured. The accumulators thus get proper treatment and care whereby their depreciation is kept within practical limits. Success in this department means considerable increase in the demand for the accumulators; this again enables the manufacturer to keep his works constantly going and thus insure uniformity of work as well as lower prices.

It is stated that all the electric light companies of Paris are supplied with accumulators from the St. Ouen works. It is needless to say this is not done from philanthropic motives. It has been found in Paris as also in many other European cities that the use of accumulators on a large scale by electric light companies is not only practical but economical. What has proved to be the case in Europe may apply equally well in America. Apparently all that is required is a principle similar to that adopted in Paris, namely, a reasonable co-operation between an installation or supply company and a manufacturing company. Some dozen tram cars have lately been started in Paris with the same type of cell.

It is to be hoped these will meet with the same financial success as those in electric lighting.

A SCHUCKERT SEARCH LIGHT FOR CHICAGO.

It is stated that the Schuckert Co. of Nuremberg, Bavaria, is to furnish a search light for the World's Fair of about 25,000 c. p. to be seen 60 miles away. Mr. F. Sargent, the electrical engineer of the Fair, will also, it is said, place two large search lights on a tower 300 feet high, with which various special effects will be obtained.

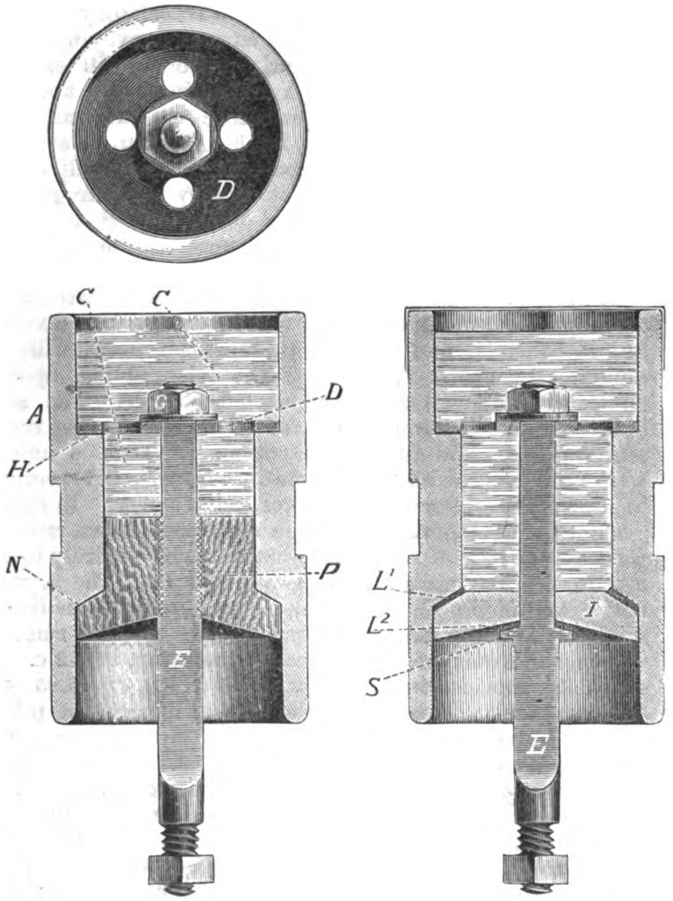
HEWETT'S IMPROVED FORMS OF THE POROUS OIL INSULATOR.

BY

R J Hewett

In The Electrical Engineer of March 30 was given a description of a porous oil insulator invented by the writer and designed specially for insulating trolley wires placed in open conduits. The process of development has produced improved forms of insulators composed of a combination of porous and non-porous insulating materials.

Figs. 1 and 2 of the accompanying engravings show respectively a sectional elevation and plan of one of the improved forms. The shell, or outer portion, is composed of a tube of well-glazed porcelain, glass or hard rubber A. Into the lower part of the smaller diameter of the tube is placed a porous plug P of wood, porous earthenware or other suitable porous material. This plug forms a bottom to the oil chamber C C. The plug P is pressed upward against the beveled shoulder N by means of the shank E, which passes through the plug and then through the perforated plate D, and is tightened up by a nut G. The perforated plate is sustained by the shoulder H. The plan view shows the perforated plate, the object of the perforations being merely to unite the upper and lower oil chambers into virtually one chamber.



Figs. 1, 2 and 3.—Hewett's Improved Porous Oil Insulators.

The oil chamber C C is filled with an insulating oil, such as paraffine, which percolates through the porous plug P and runs off on its conical underside to the inner surface of the porcelain tube, down which it flows in a continuous film to the edge, where it drips off.

A groove round the centre of the insulator is provided for receiving a clasp, by means of which it can be attached to the side of the conduit or manhole. A wire holder is attached to the lower end of the shank E. The porous plug P is composed of fine-grained wood, thoroughly seasoned by a special process which drives out all air and resin and thoroughly shrinks the plug so that no further shrinkage can occur.

In Fig. 3 is shown another form of insulator, in which the porous part is reduced to still smaller dimensions. The bottom of the oil chamber C is composed of a disc of non-porous material I, through the centre of which passes the shank E. A washer of felt L^2 is placed between the shoulder S of the shank and the disk I. Another porous washer L^1 is placed between the beveled shoulder of the tube and the edge of the disc. The oil percolates through these two porous washers and runs down on the surface of the disc and bell as in the other forms. By adjusting the nut G the compression on the porous washers can be varied and the quantity of oil fed through can be regulated. The cap J serves as a covering for the oil so as to exclude dust, etc.

ELECTRIC RAILWAY POLE-LINE CONSTRUCTION.

BY

W. F. D. Crane

PART II.—WOODEN POLES.

Outside of the appreciable saving in first cost, and, perhaps, less need for care and expense in the insulation of the trolley line, since wood is itself a partial non-conductor, wooden poles are not desirable where reliable and permanent construction is sought. In order to obtain the strength necessary to support the overhead construction, wooden poles have to be of considerable bulk, which detracts from the appearance of the street. Moreover, wood deteriorates with comparative rapidity; the pole continually yields under the strain, necessitating the frequent adjustment of span wire or the resetting of the pole; and, unless inspected and painted frequently with a care seldom given, the poles rot rapidly at the ground line where the breaking strain is greatest. It is therefore possible, in view of the rotting which is not always accessible or easy to detect, to have an accident, which at a comparatively early date shall not only inflict a local damage but destroy a considerable portion of the line. It is the existence of these contingencies, together with lack of strength and the difficulty of adequately avoiding early deterioration, that create the demand for the very much stronger and more expensive iron pole, as noted in Part I of this article.

There are, however, frequent uses for wooden poles, dictated by economy or other considerations (as in the case of towns with small traffic), extensions into sparsely settled territory, connections through open country between populous centres; or similar cases where wooden poles most economically answer the purpose and can be used to advantage.

Poles of pine, cedar, chestnut, spruce, cypress, tamarack and other woods are most frequently in demand. Of these spruce, cypress and tamarack, and occasionally poplar, have been used, more especially in or near the localities in which they are procurable. Spruce, when set, makes a handsome line, possessing strength and elasticity, but its short life of two or three years makes its ultimate cost expensive and renders it fit for temporary construction only. Cypress and tamarack both possess excellent lasting qualities. The cost of transportation and the uncertainty of the supply has, however, to a large extent limited their use in northern fields where other woods are more easily obtained.

Cedar, pine and chestnut are abundant, and poles are usually selected from one of these woods. White cedar and chestnut are selected both for their cheapness, quick delivery and railway qualities. Pine, whether of the Michigan or so-called Norway pine, or of the Georgia or North Carolina so-called yellow pine, is the wood usually used for manufactured poles. These manufactured poles are made with a wide variety of shape and finish according to the choice of engineer or maker. Some have the body of the pole turned round, others sawed square or octagonal, with butt full size of the natural wood; others have the same general shape the full length of the pole.

Cost, quantity, time required for delivery and other considerations will naturally affect the choice of pole where little attention is given to the appearance of the line. Undoubtedly, where wood is used, the manufactured pole, with preference for the octagonal, for streets in towns, presents the best appearance.

Following is a list of standard sizes of octagonal pine poles for railway purposes:

6-inch top.	9-inch butt.	28 feet long.
7 "	10 "	28 "
8 "	11 "	28 "
6 "	10 "	30 "
7 "	11 "	30 "
8 "	12 "	30 "

The specifications should read as follows:

Pole to be — ft. long; — in. top; — in. butt; sides to be sawed uniformly octagonal and top neatly pointed; timber to be selected straight, free from knots and shakes, sides to be painted with one coat of paint; butt to be painted for six feet with asphaltum or other preservative compound.

The specifications of a Georgia pine pole to be used on street 60 feet or less wide, drawn up by some engineers, call for a pole 28 feet long, 7-inch top, 10-inch butt, to be sawed square, with edges chamfered and top pointed.

Orders for round or natural wood poles should specify that poles must be live, sound timber; butts cut, well proportioned and reasonably straight; peeled, knots trimmed smooth; and suitable for electric railway (or wire carrying) purposes.

Present practice has almost entirely abandoned the use of the 6-inch top pole for side-pole construction and requires poles with 7-inch tops for streets 30 to 40 feet between curbs; 8-inch tops for streets 40 to 60 feet between curbs; 10-inch tops for pull-off or strain poles, and in the case of round wood poles, demands the largest butts obtainable.

Centre poles on straight tracks may, if circumstances permit, have 6-inch tops, on account of the lighter strain they are called upon to bear. Where centre poles are liable to suffer damage from collision with vehicles, they should be protected by substantial wheel guards or an iron sheathing extending two or more feet above the ground. Centre poles on curves subjected to side strains should be well guyed and be heavier than those used on the straight line. Bracket-arm poles should preferably have at least 7-inch tops except on curves, where they follow the above rule for centre poles.

As mentioned in the early part of this article, wooden poles quickly deteriorate unless subjected to frequent inspection, and unless means be used to protect the wood against weather influences and contact with ground moisture. Before setting, the butts for a foot or more above the ground should be thoroughly saturated with hot tar or painted with one of the penetrating preservative compounds sold for this purpose. Too much care cannot be given to this process; upon its thoroughness will depend in large measure the future life and reliability of the pole. Both before and after setting the poles should be painted, and painted thereafter as often as they require it.

Many of the remarks in Part I relating to iron poles, referring to setting in concrete, allowances for rake, elastic limits, tension of span wire, lengths of poles for side, centre or bracket-arm construction and other considerations, will be found applicable to wooden poles.

THEORETICAL ELEMENTS OF ELECTRO-DYNAMIC MACHINERY—IV.[1]

BY

A. E. Kennelly

POTENTIAL DISTRIBUTIONS (*Continued*).

An important system of flux and potential distribution is that established within an endless solenoid, or what is practically a helix with its two extremities united. Such a solenoid completes its magnetic circuit entirely within itself and has no exterior flux. It therefore has no external magnetic potential. In the practical application of this case, attention has sometimes to be paid to the departure from the strict definition of a solenoid, for a helix is virtually a solenoid plus a conductor along the axis, just as motion along a spiral is circular plus a translatory advance in the axial line; so that a closed current conveying helix, however closely wound, and nearly uniform, will exercise some attractive influence upon a magnetic needle, and thus evidence an external flux, unless before the extremities of the coil are joined, one wire be led back to its starting point parallel to the axis, a proceeding which will cancel out the axial component except at very close range. At all ordinary distances, the closed helix will then be deprived of external magnetic influences, no matter how tortuous the curve its axis may follow.

Within this closed solenoid there will be a distribution of magnetic potential, but it will be complex, as also the flux it controls, and difficult to represent graphically or numerically, unless the axis of the solenoid lies upon a circle. In this case the distribution is simple. The solenoid will then assume the form of an anchor ring represented in plan and diametral sections by Figs. 6 and 7, where N O P is the axis of revolution, Q R S, T U V, sections of the helix surrounding the coil axis G H K. In such a system the equipotential surfaces are planes drawn radially through the axis of revolution, but confined entirely to the interior of the ring, such as AD, WX, and YZ. The M. M. F. active within the ring is 4π times the current turns linked with it. If there were 180 turns of wire on the ring, as shown, and a current of 2 amperes circulating, or 0.2 C. G. S. units, the E. M. F. would be $4\pi \times 180 \times 0.2$, or 45.25 ergs per unit pole.[2] This will be the total difference of potential for one complete circuitation within the ring, representing a rate of change of potential of 0.1257 erg on unit pole per degree of revolution round the axis N O P. This gradient is definite, but the potential at any plane is arbitrary, and may be selected at will as a starting point. Once chosen, the potential is evidently cyclic, and increases or diminishes by $4\pi nc$ ergs in each revolution, according to the direction of circuitation. If there is more than one layer of wire on the ring, and each layer be uniformly wound, the system may be considered as a combination of independent solenoids, one for each layer. The potential in the interior will be that due to the sum of the solenoids, while at any point in the winding space the potential will be that due to the layers outside, those within the point's axial radius having no influence beyond their surface.

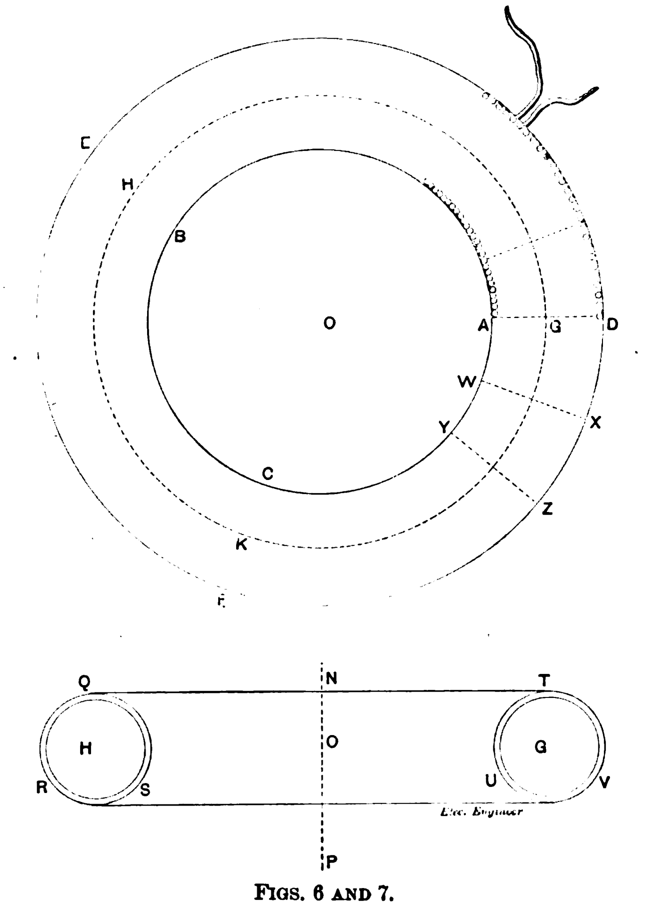
Within the anchor ring, the flux, necessarily perpendicular to all the successive equipotential planes must follow circles concentric with the axis of revolution N O P. The intensity will be uniform along any one circle, and will be equal for equal circles, but it would be different in circles of different radii, being weakest at the outer side D E F, and strongest at A B C, varying inversely as the radius of revolution. With reference to what has appeared in Part II, on the field surrounding an infinite straight conductor, it is evident that any steady current c making n uniform turns round an anchor ring of wood or other non-magnetic material, produces throughout its interior exactly the same distribution of potential and flux that a current of nc units flowing along the ring's axis of revolution indefinitely prolonged would produce throughout all space. The circular solenoid produces within the finite limits of its interior the condition that an infinite conductor would establish in infinite space.

---

[1] Copyrighted 1892 by A. E. Kennelly.

[2] The dimensions of magnetic potential being $M^{\frac{1}{2}} L^{\frac{1}{2}} T^{-1}$, magnetic pole $M^{\frac{1}{2}} L^{\frac{3}{2}} T^{-1}$ and energy $M L^2 T^{-2}$, it is important to observe that potential is equivalent to energy ÷ pole, and when expressed in ergs, implies ergs expended on or by a unit pole.

This analogy suggest what is, in fact, readily proved, that the radial planed system of potentials and circular distribution flux is not dependent upon the cross-section of the solenoid. We have thus far supposed it to be circular, but it might be square, elliptical, or of any arbitrary shape, provided that its surface was a surface of revolution, having the equivalent straight wire for its axis. The field due to the equivalent current along the infinite axis would still reside within the coil. From the results in Part II, the magnitude of B would be there represented by $\frac{4\pi nc}{2\pi r}$, or $\frac{2nc}{r}$, where r is the radial distance of the point considered from the axis of revolution. In a solenoid whose cross-section is of small dimensions compared with the radius of revolution, B is nearly uniform in intensity, and if the cross-sectional area be denoted by a, the flux within the solenoid will then be $\varphi = Ba = \frac{2nca}{r}$. If, however, the cross-section of the solenoid be of such shape and dimensions that the intensity varies considerably in different parts of it, the area must be multiplied by the average B to give the total flux, or by the flux intensity existing at the centre of gravity of the area, considered as a thin material lamina.



Figs. 6 and 7.

The general case of potential distribution round a current has been only determined in a comparatively small number of instances of which the foregoing are the simplest examples. Yet in order to determine the distribution of flux existing through space in the vicinity of a given system of conductors, it is usually simpler to calculate the distribution of potentials when it exists, and deduce the flux from the gradient, than to compute the general value of B directly. The difficulty in either case is essentially one of summation, for each small element of a current-conveying conductor contributes its own share to the potential or flux at a point independently of all the others, and the geometric sum of all these elementary potentials or intensities is the resultant at that point.

The rule for determining the magnetic potential of any circuit at any point is as simple as it is often difficult to numerically apply. Let a sphere of one centimetre radius be described round that point as a centre, and let a straight line commencing at this point centre move round the circuit considered, in the direction of the current. The trace of its path cut on the unit sphere will form some closed curve and the area of the spherical surface enclosed will be the solid angle subtended at the point by the circuit. This, multiplied by the strength of the current, will be the point's potential. This shows that for circuits comprised in one plane, the potential of that plane is everywhere zero, or some multiple of 4 π, for the solid angle subtended by the circuit will vanish at any point upon it. Also, if two or more loops in a circuit stand behind one another when viewed from a point, so that the radius vector makes reentrant loops on the unit sphere in contouring them, the overlapping areas must be added to the total surface within the boundary, or, in other words, the potentials of superposed loops are superposed.

THE PRACTICAL MANAGEMENT OF DYNAMOS AND MOTORS.—XI.

(*Concluded.*)

BY

Francis B. Crocker and S. S. Wheeler.

Chapter VII (*Concluded*).

7. *Voltage.*—There is no convenient way of testing voltage except by means of a voltmeter. Unfortunately a really satisfactory voltmeter is rather an expensive instrument. A good voltmeter should be very accurately calibrated because an error of one per cent. in the voltage of an incandescent circuit is objectionable, whereas the same error would be insignificant in almost any other practical measurement. A voltmeter should have as high a resistance as possible—at least several hundreds or thousands of ohms—in order not to take too much current which might lower its reading on a high resistance circuit. It should not be affected by the magnetism of a dynamo or motor at any distance over four or five feet. The voltage of any machine or circuit is tested by merely connecting the two binding posts or terminals of the voltmeter to the two terminals or conductors of the machine or circuit. In the case of a dynamo or motor the voltmeter is usually applied to the two main binding posts or brushes of the machine to get the external voltage of the machine. This external voltage is what a dynamo supplies to the circuit and it is what a motor receives from the circuit. This is called the pole difference of potential or terminal voltage and is the actual figure upon which calculations of the efficiency, capacity, etc., of any machine are based.

A dynamo for constant potential circuits should, of course, give as nearly as possible a constant voltage. A plain shunt machine usually falls from 3 to 10 per cent. in voltage when its current is varied from nothing to full load. This is due to the loss of voltage in the resistance of the armature, which in turn weakens the field current and magnetism; armature reaction and reduction in speed usually occur also and still further lower the external voltage, but of course this variation is very undesirable. A compound-wound dynamo should not fall appreciably from no load to full load; in fact, if it is "over-compounded," it should rise two or three per cent. in voltage to make up for loss on the wiring. The voltage of a constant current dynamo or motor is not important. The current should be carefully measured by an amperemeter, but little or no attention is paid to the voltage in practical working; in fact, it changes constantly with variations in the load. It is of course necessary, however, to measure it for a test of efficiency or other exact tests.

A very simple and fairly accurate method of measuring voltage is by means of ordinary incandescent lamps. A little practice enables one to tell whether a lamp has its proper voltage and brightness. In this way it is easy to tell if the voltage is even one or two per cent. above or below the normal point. Voltages less than the ordinary can be tested by using low voltage lamps or by estimating the brightness of high voltage lamps. For example, a lamp begins to show a very dull red at one-third and a bright red at one-half its full voltage. Voltages higher than that of one lamp can be tested in this way by using lamps in series. In fact, even 1,000 or more volts can by measured by using 10 or more lamps in series.

8. Current.—This is, of course, measured by means of an amperemeter, and this instrument is usually cheaper than a voltmeter because it only contains a comparatively small amount of wire, and does not ordinarily require to be accurate within one or two per cent. In testing the current of a dynamo or motor all that is necessary is to connect an amperemeter of the proper range in series with the machine to be tested so that the whole current to be measured passes through the instrument. To test the current in the armature or field alone, the amperemeter is connected in series with the particular part. In the case of a shunt-wound dynamo it is well to entirely open the external circuit in testing the current used in the field coils in order to avoid mistake, for the same reason the brushes of a shunt motor should be raised while testing the current taken by the field. In a constant current (series wound) dynamo or motor the same current flows through all parts of the machine and the rest of the circuit, consequently the measurement of current is very simple.

In testing the current produced by a dynamo it is often quite a problem to consume it. A bank of lamps, for example, to use the whole current generated by a dynamo of 110 volts and 200 amperes would be very expensive. A sufficient number of resistance boxes for the purpose would also be very costly. The simplest and cheapest means to consume a large current is to place two plates of metal or carbon in a common tub or trough filled with a very dilute solution of sulphate of soda or sulphuric acid. The main conductors are connected to the two plates, respectively, and the current passed through the solution. The resistance and current are regulated by varying the distance between the plates and the depth they are immersed in the liquid. The energy may be sufficient to boil the liquid but this does no harm.

9. Speed. This is usually tested by the well-known speed meter or speed counter which consists merely of a little spindle which turns a wheel one tooth each time it revolves. The point of the spindle is held against the centre of the shaft of the dynamo or motor for a certain time, say, one minute or one half minute, and the number of revolutions is read off from the position of the wheel.

Another instrument for measuring number of revolutions per minute is the tachometer. The stationary form of this instrument is shown in Fig. 27. This requires to be belted by a string, tape or light leather belt to the machine the speed of which is to be tested. If the sizes of the pulleys are not the same, their speeds are inversely proportional to their diameters. The portable form of this instrument is applied directly to the end of the shaft of the machine like the speed meter. These instruments possess the great advantage over the speed meter that they instantly point on the dial to the proper speed and they do not require to be timed for a certain period.

A simple way to test revolutions per minute is to make one large black or white mark on the belt of a machine and note how many times the mark passes per minute; the length of the belt divided by the circumference of the pulley gives the number of revolutions of the pulley for each time the mark passes. If the machine has no belt, it can be supplied with one temporarily for the purpose of the test, a piece of tape with a knot or an ink mark being sufficient. Care should be taken in all these tests of speed with belts, not to allow any slip; for example, in the case of the tape belt just referred to, it should pass around the pulley of the machine and some light wheel of wood or metal which turns so easily as not to cause any slip of the belt on the pulley of the machine.

10. Torque or Pull is tested in the case of a motor by the use of a Prony brake. This consists of a lever L L of wood clamped on to the pulley or shaft of the machine to be tested, as indicated in Fig. 28. The pressure of the screws S S is then adjusted by the wing nuts until the friction of the clamp on the pulley is sufficient to cause the motor to take a given current and run at a given speed. Usually the maximum torque or pull is the most important to test and this is obtained in the case of a constant potential motor by tightening the screws S S until the motor draws its full current as indicated by an amperemeter. What the full current should be, is usually marked on the name plate; if not, it may be assumed to be about 8 amperes per h. p. for 110-volt motors, 4 amperes per h. p. for 220-volt and 1¾ ampere per h. p. for 500-volt motors. The torque or pull is then measured by known weights, or more conveniently by a spring balance P. If desired, the test may also be made at three-quarters, one-half or any other fraction of the full current.

The torque or pull of a constant current motor is found by adjusting the screws S S until the armature runs at its normal speed.

The torque or pull of a dynamo, that is, the force required to drive it, is tested by a transmission dynamometer. There are several forms of this apparatus but none of them are very satisfactory. In the cradle dynamometer the dynamo is placed on a platform which is hung on a pivot or fulcrum. The axis of the shaft of the dynamo is adjusted so that it exactly coincides with the axis of the pivot or fulcrum. When the dynamo is run by a vertical belt, the pull or torque tends to cause the dynamo to turn about its axis of suspension, and the force of this torque is measured by the amount of weights required to keep the dynamo and platform horizontal. In a modified form of the cradle dynamometer the dynamo is placed in a water-tight box which floats in another box filled with water, instead of being hung on a pivot. It is usually much easier to test the torque of a dynamo by running it as a motor and testing it by the Prony brake method described above. The torque of a dynamo is practically equal to that of a motor under identical conditions.

11. Power.—The electrical power of a dynamo or motor is found by testing the voltage and current at the terminals of the machine, as described in sections 7 and 8 of this chapter, and multiplying the two together, which gives the electrical power of the machine in watts. These watts divided by 746 are then converted into horse power, thus:

$$\text{Horse power} = \frac{\text{volts} \times \text{amperes}}{746}.$$

The mechanical power of a dynamo or motor, that is, the power required for or developed by it is found by multiplying its torque or pull, determined as described in the previous paragraph, by its speed, determined as described in section 9 of the present chapter, and by the circumference of the circle on which the torque is measured, and dividing by 33,000, that is—

Horse power $= \dfrac{P \times S \times 6.28 \times R}{33,000}$ in which P is the torque in pounds, S the speed in revolutions per minute and R the radius at which P is measured.

12. Efficiency.—This is determined in the case of a dynamo by comparing the mechanical power required to drive it by the electrical power generated by it, that is—

$$\text{Efficiency of dynamo} = \frac{\text{Electrical power}}{\text{Mechanical power}}.$$

The efficiency of a motor is the mechanical power developed by it divided by the electrical power supplied to it, that is—

$$\text{Efficiency of motor} = \frac{\text{Mechanical power}}{\text{Electrical power}}.$$

These are the *actual* or *commercial* efficiencies of these machines and should be about 90 per cent. in machines of 10 h. p. and over.

The so-called "electrical efficiency" is misleading and of little practical importance and should not be considered in commercial work. The mechanical and electrical power in the above equations are determined as described in the last section.

13. Heating.—This is measured by applying a thermometer to the various parts of the machine, after it has run at full load for one or two hours, in fact a large machine does not reach its maximum temperature until it has run for three or four hours.

The bulb of the thermometer is applied directly to the surface of the field coil or other part. To test the armature it must, of course, be stopped. The thermometer bulb should be covered over with a bunch of waste or cloth to keep in the heat. The temperature of the armature, field coils, bearings, etc., should not rise more than 40° C. or 72° F. above that of the surrounding air. A very simple test of heating is to apply the hand to the armature, etc., and if it can be kept on without great discomfort, the temperature is perfectly safe. See "Heating" in chapters on Locating Faults.

14. Sparking at the commutator cannot be actually measured, but it is a very important matter and in any test it should be carefully observed whether the sparking is excessive or not, and if so, what it is due to. (See "Sparking" in chapters on Locating Faults.)

15. Magnetism.—Magnetic measurements are difficult to make with the ordinary apparatus used in practical work. The proper method of testing magnetism is with the ballistic galvanometer. To test the magnetic leakage in a dynamo or motor, for example, a coil of wire connected to the galvanometer is put around the field magnet and the current in the field is stopped the deflection of the galvanometer needle being noted. A coil of the same number of turns is then put around the armature and the swing of the galvanometer is again noted. The first deflection is to the second as the number of lines of magnetic force in the field is to those in the armature, provided the angles of deflection are only a few degrees.

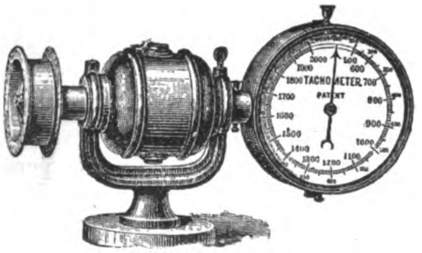


FIG. 27.

An ordinary detector galvanometer can be used for this work if it is not damped by wings to prevent its swinging freely. A low-voltage Weston voltmeter or the calibration coil of a high-reading one, can also be used very conveniently for magnetic measurements in place of the galvanometer as described by A. S. Ives in the *Electrical World*, Jan. 2, 1892.

16. Line or Circuit testing for resistance, insulation, current, voltage, etc., is performed by exactly the same methods as those just described for making the corresponding tests on dynamos and motors. For example, in testing the insulation resistance of a line or circuit, one wire is connected to the line and the other to the ground (a gas or water pipe is convenient for this purpose) instead of connecting one wire to the commutator and the other to the frame of the machine as described for testing the insulation resistance of a dynamo, otherwise the test is exactly the same.

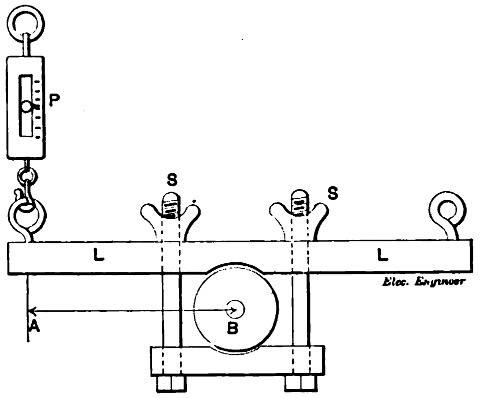

FIG. 28.

THE EXHIBITION OF THE SOCIETE FRANCAISE DE PHYSIQUE.

THE annual exhibition of the Société Francaise de Physique was held on the 19th, 20th and 21st ult, in the building of the Société d'Encouragement. Among the more noteworthy events forming part of the proceedings was a repetition by M. d'Arsonval of the Tesla and Elihu Thomson experiments. The experiments were very successful, and many were of a novel character. M. d'Arsonval made a great point of showing the difference in the physiological effects of alternating currents of different kinds. M. P. Janet showed an apparatus for the stroboscopic study of alternating currents. MM. Richard Frères showed an electric kinemograph, and a hydraulic dynamometer, which had been used in determining the variation of tractive effort with the speed of a vessel. The same firm also showed a Deprez-d'Arsonval galvanometer which registered photographically. M. Ducretet showed some apparatus constructed for carrying out experiments with polyphase currents, and M. Besson exhibited a small plant arranged to enable accumulators to be charged by means of the Giraud thermo-electric stove.

AN ELECTROMAGNETIC LIGHT COIN DETECTOR.

MESSRS. NAPIER & SON show at the Crystal Palace Exhibition an electromagnetic light coin rejector for the use of bankers or mints. The coins are pushed in succession from the balance pan onto a knife-edge, and according as this knife-edge is at the right-hand limit of its range, or the left-hand limit, the coin, when pushed on it, tilts off to the "light" channel or the "full-weight" channel as the case may be. The right or left position of this shifting knife-edge is determined by an electric contact made by the balance beam; this brings an electromagnet into action. The coins are run through the machine at the rate of about sixty per minute by the action of turning a handle.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIII. NEW YORK, MAY 18, 1892. No. 211.

It is the due combination of theoretical knowledge with practical skill which forms the most efficient and reliable character.--Joseph Henry.

WHAT ELECTRICITY IS.

THE discussions as to the nature of electricity which stir the electrical fraternity from time to time, and which, like the sun spots, break out from no assignable cause, if they have not led to a definite solution of the question nevertheless serve as periodical reminders of the fact that the world is still in ignorance; and hence to that extent at least they serve a useful purpose. One of the peculiar phases which these discussions have of late assumed is a development of what, for want of a better term, we may call the "corpuscular theory" of electricity, the adherents of which seek to prove that electricity is "ether in motion," that is, that an electric current is due to an actual transfer of ether particles, or, to use a mechanical analogy, that a dynamo is an ether pump. Thus far the adherents of this theory have based their arguments on purely theoretical deductions but a recent attempt to prove the theory experimentally deserves some notice. This has been undertaken by Dr W. W. Jacques who, in an address delivered before the American Academy of Arts and Sciences, in Boston, gives the results of his experiments. Before citing the results actually reached by him, Dr. Jacques sought to prepare the minds of his hearers by a series of analogies in which he characterized a current of electricity as a "breeze of light." He also likened the action of the ether breeze to a breeze of air, the weathervane of the former being the magnetic needle, and its anemometer the galvanometer. We pass over the slight fault in this analogy due to the fact that the magnetic needle points at right angles to the direction of the supposed ether breeze, in order to give another analogy which the lecturer appears to have looked upon as of special importance in proof of his theory. If we send a steady current of electricity through a wire, we get no inductive effect in a neighboring conductor; but interrupt the current, so that it pulsates, say 100 times per second, and we get current effects of the same frequency in the second conductor. Now, take a pipe carrying a steady current of air; it emits no sound. But break up the current of air into 100 pulsations per second, such as might be done by an organ pipe, and the ear perceives a sound, due to the radiated air waves. According to Dr. Jacques, "analogy indicates that, in the former case, we have a current of ether (or electricity), by rapid interruptions, converted into waves in the ether (or electrical waves)." We agree with Dr. Jacques that we must have stronger proofs than the indications of analogy, and hence we come at once to the crucial experiment devised by him to show the identity of the electric current and a current of ether. This is based upon a conception of Clerk-Maxwell to illustrate the relationship between the electrostatic and electromagnetic units. For this purpose Dr. Jacques employs a pair of discs attached respectively to the arms of a delicate balance, and placed so that each swings freely between a pair of discs, one placed above and the other below the disc attached to each balance arm. There are six discs in all. Theory indicates that if the discs be similarly charged electrically there will be no mechanical action between them, if they be moved with the velocity of light, 300,000,000 metres per second. Dr. Jacques has undertaken to measure the action which does take place at the velocity at which the earth moves in its orbit around the sun, combined with that of its approach towards the centre of star drift in the constellation Hercules. In order to get definite results, Dr. Jacques works on the differences in these combined velocities resulting from the varying positions of the earth in its orbit. On March 22 the star-drift velocity would have to be added to that of the orbital velocity, and on September 21, subtracted. On December 22 it would have no effect. According to Dr. Jacques, on March 22 the velocity of a point in space, at the Hub, say, should be $\frac{1}{2000}$ the velocity of light; on December 22, $\frac{1}{2500}$; and on September 21, $\frac{1}{2700}$. The balance is employed to measure these differences. Dr. Jacques began his experiments last September, and the results observed are of the order of the magnitude predicted, though he states that accidental phenomena frequently masked that for which he was searching. It is scarcely necessary to comment critically on a series of confessedly incomplete experiments, but we fail to see how, even if Dr. Jacques' experiments end as he expects, they will prove in the least that the electric current is a *bodily forward movement of the ether*. He will merely have shown again the correctness of the theory that a moving electrified body is equivalent to an electric current, but in a manner far more cumbersome and subject to error than the beautiful experiment performed by Rowland in 1876, and by others in various ways. While electromagnetic phenomena, above all others, are interconvertible, we are scarcely justified in assuming that the effect of, or force created by, a relative motion between two bodies, *is* the motion of one of these bodies itself.

STORAGE BATTERIES IN CENTRAL STATIONS.

Our recent remarks on the above subject have served to bring out a communication which we print on another page and which is well calculated to demonstrate that for central station work the storage battery has already proved itself a powerful factor of economy. Perhaps the most characteristic feature of the cells in the Paris installations is the size of the individual plates, which in this respect are a decided departure from, and, we believe, an improvement over, the size we are accustomed to associate with cells of this nature. This is a step in the right direction and the advantages gained by their adoption are too obvious to require further comment. But aside from the manner of operation of the stations detailed by Mr. Currie, there is another important feature embodied in the arrangement as it exists in Paris and which we think might be adopted in our country to good advantage. The efficiency of the cells being guaranteed by the manufacturing company and their remuneration being dependent upon the percentage of efficiency, allows the installing and distributing company in the first place to estimate exactly the relative advantages to be derived from the storage cells, while, on the other hand, it secures to them that freedom from the disputes which have only too often resulted in the total abandonment of storage battery work. With a feasible way, as shown abroad, of operating with storage cells it ought not to be difficult to inaugurate the system generally among American central stations; and we do not hesitate to say that a company prepared to furnish and maintain storage batteries and to guarantee their performance at a fixed annual charge will find a large business awaiting them.

FEEDER-AND-MAIN PATENTS.

We have surrendered a considerable amount of space in our current issue in order to present as adequately as possible the points in contest in the hearing on Edison's patent for feeder-and-main distribution, which has just terminated in the United States Court at Trenton, N. J. There is scarcely a central station plant in existence, in this country or abroad, which does not use the arrangement of circuits claimed to be covered by this patent, and hence the dicussion can hardly fail to interest a large constituency of electrical engineers. The real question at issue has been practically narrowed down to the inquiry whether the arrangement of circuits in controversy constitutes a patentable invention, or whether it amounts to nothing more than a well-conceived engineering expedient. The determination of this question in the present case, is by no means easy. A good deal can be said, and, in fact, a good deal has been said, on both sides of the question. In fact, it is by no means easy to sufficiently instruct a judge, however able and intelligent, in the technicalities of electrical science, merely by a few days of argument, so as to enable him to understand thoroughly the point at issue. The Edison Company have however, set up in the court-room a most effective object-lesson, a description of which will be found elsewhere, consisting in part of a full-sized and complete set of central station apparatus for distribution and regulation, which will enable the whole operation to be understood almost at a glance. The arguments of counsel pro and con have occupied the attention of the court for more than a week, but we have succeeded in presenting the essence of them in our report in another column.

SWITCHING RAILROAD TRAINS BY ELECTRICITY.

Inspector Brettman, of the Prussian State Railways, writes to the *Deutsche Bauzeitung* to suggest the use of electric power for switching cars, and calls attention to the high cost of switching by locomotives. The annual statement for the fiscal year 1889-90 showed that the switching on the Prussian roads required over ten million locomotive-hours, the fuel alone costing $1,500,000. On adding to this the wages of the engineers and firemen, it appears that 19 per cent. of the cost of the train service is spent on the switching.

Inspector Brettman thinks a cheaper and more serviceable motive power can only be found in electricity, which will soon make its way into railway stations for lighting purposes. He thinks of so arranging electric windlasses between the tracks, that several may be used simultaneously for moving a heavy train, while one would suffice for a few cars. In certain cases he would advise the use of motor cars with gears engaging a rack alongside of the track, these cars being moved from track to track on a sliding platform or turntable. This latter plan, with the substitution of a magnetic traction increaser for the rack and pinion would probably adapt itself to American practice and would seem worthy of attention here as well as abroad. It is evident that the range of travel of a switch-engine is very small as compared with even a horse car, and therefore it is not so much the cost of the long transmission lines, as the feasibility of operating motors on zig-zag tracks, which will govern the use of electrical energy for this purpose.

THE MEETING OF THE INSTITUTE IN CHICAGO.

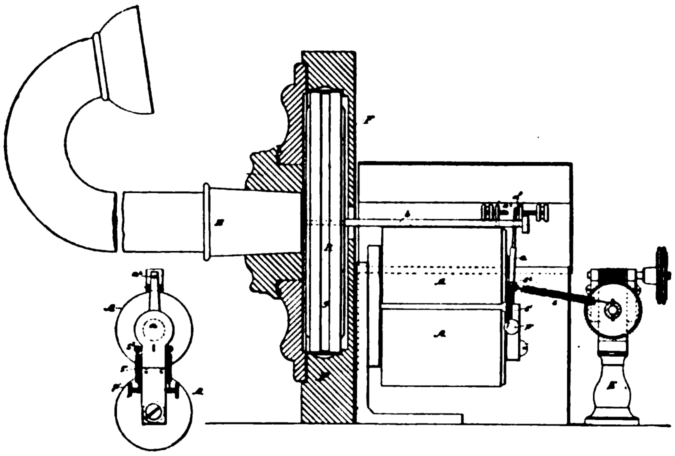
We published last week the preliminary programme of the meeting to be held by the Institute in Chicago next June. It is perhaps the best selection of topics that the Institute has ever had, while the authors are such as to insure a thorough treatment of the questions discussed. It is worthy of note that on the occasion of this visit of the Institute to Chicago—the first Western trip in its history—the West is conspicuously represented on its programme. We observe that it will have contributions not only from well-known engineers in Chicago, but from the universities of Minnesota, Nebraska, Wisconsin and Ohio. This is altogether as it should be, and it is most satisfactory to find the national technical body thus in touch and sympathy with the advanced thought and practice of the great progressive West. It is an interesting fact that while the membership and officers of the Institute have always been very largely drawn from outside New York—as becomes a national body—the proportion of members in the West has not until within the last year or two been fully representative of electrical activity there. New York and vicinity has perhaps never had more than a bare 25 per cent of the membership, while the remainder is scattered all over the Union and all over the world. Of the presidents, only two out of seven have been residents in New York State.

THE SECRET TELEGRAPH RECEIVER.

BY

A. A. Knudson.

It is a well-known fact, that owing to the present general system of telegraph receiving apparatus, such as the loud clicking sounder, a large amount of "leakage" of telegraphic communication is daily going on. A short time ago a number of old telegraphers were discussing this point, and the number and frequency of such incidents which were related was surprising. The usual method employed is very simple and very rarely detected. An operator may be carelessly lounging in the vicinity of a way station, such as a railway office, with his hands in his coat pockets, one hand being busy with a short pencil taking down on a pad important information which the accommodating sounder ticks off and that later may be used to the disadvantage of the sender; or he may be innocently looking over the tape at the stock quotations in a broker's office, while the click of the sounder in a back room informs him what the firm is doing in its operations at the exchange, or other information equally important by no means intended for his ear.



Figs. 1 and 2.—Knudson's Secret Telegraph Receiver.

With a view to trying what could be done by such eavesdropping the writer a short time ago employed an expert operator to call at some of the brokers' offices about Wall street and also some of the hotels in the city to see what he could get in the way of information. Out of some dozen offices he visited he was able to obtain information more or less important from every one of them, and as for the hotels, nothing was easier than to take every message he chose.

In view of the above and of much more evidence that could be furnished it seems there is a demand for an instrument that will not "leak." I have therefore completed a device which so far as it has been tried seems to fill the bill and is constructed as follows:

Referring to the engraving Fig. 1, the magnets A A are used to actuate the armature *a* which is more clearly shown in Fig. 2. Two pointed studs project from its lower part and stand on the concave bottom of holes drilled in the pole extension of the magnet. The armature is held in place by the spiral springs s^1 secured to the adjusting screws p^1. The effect of this arrangement is to reduce the amount of armature friction to a minimum and also bring the magnetic poles of the instrument close together, thereby obtaining the fullest amount of power from the magnet. A special adjusting screw for the retractile spring being clearly shown in Fig. 1 need not be described. The limiting screws a^2 a^3 are secured to the arms *b*, these arms being fastened to a resonator R, of peculiar construction, which is placed in the wooden case F.

This resonator is constructed as follows: Two thin sheets of aluminum are spun in a round shape with corrugated surfaces and with edges turned over, these are slipped over the sides of a band of brass about ½ an inch wide as at *g*, Fig. 1. The whole is about six inches in diameter.

It will be observed that as the limiting screws against which the armature lever plays are in direct metallic connection with the resonator, any movement of the armature, however small, is easily heard at the receiving tube H of the instrument. As a matter of fact, the instruments, as generally constructed, are kept adjusted so closely that no movement of the armatures can be detected with the naked eye, nor can the sounds be heard without holding the ear close down to them; at the receiving tube, however, which takes up the faintest sound from the resonator, the telegraphic signals can be easily read.

It will be noticed that the important results obtained in the magnifying of sound as shown in this instrument are largely due to the excellence of the resonator; in its construction advantage is taken of the well-known sonorous quality of aluminum, which exceeds in this respect all other metals. Other features of importance are the ability to operate lines equipped with instruments of this kind with a very small amount of main battery, and also doing away with the sounder and local battery.

A test of this instrument was recently made between New York and Hartford, a distance of about 140 miles, on a line of the Postal Telegraph-Cable Co. The result showed that a very much less amount of battery was required to operate the line, and the signals were easily read on an extremely small movement of the armature, due, as before stated, to the magnifying qualities of the resonator.

THE COMMELIN-FINOT CADMIUM ACCUMULATOR.

The positive plate of this accumulator, says *L'Industrie Electrique*, is an ordinary Julien positive; the negative plate being preferably an alloy of lead, cadmium and antimony. The liquid is a solution of sulphate of cadmium, to which 10 per cent. of sulphuric acid is added. MM. Commelin and Finot also propose to employ a positive plate formed of twisted lead strip, holding plugs of lead chloride. On charging, the oxygen oxidizes the positive plate as usual, and metallic cadmium is deposited on the negative plate. On discharging, the cadmium combines with the sulphuric acid, cadmium sulphate being re-formed, and the hydrogen liberated from the sulphuric acid goes to the positive plate and reduces the peroxide. The inventors anticipate by this arrangement the complete avoidance of sulphating. The electromotive force of the cell is stated to be 2.5 volts on open circuit, and from 2.2 to 2.15 volts during discharge. The output per pound of plate is 24.5 watt hours.

ELECTRICITY IN THE MANUFACTURE OF WHITE LEAD.

Ammonium acetate is used for dissolving the litharge in the production of basic carbonate of lead—the so-called "white lead" of commerce. The solution is ordinarily used over and over again, and in course of time becomes impure through taking up considerable quantities of copper—an impurity in the litharge. One of the latest improvements employs carbonic acid gas for removing every trace of metal from the acetate, but another improvement, which is said to be even more effective, is to pass through the solution an electric current, electrodes of carbon being employed. In another application of electricity to white lead making, the metallic lead itself is decomposed in an acid electrolyte into an oxygen bearing salt of the metals; the saturated solution being then neutralized, and the salts contained in it being converted into hydrated lead carbonate. The latter is precipitated by the introduction of carbonic acid gas.

Legal Notes.

FINAL HEARING ON EDISON'S "FEEDER AND MAIN" PATENT FOR ELECTRICAL DISTRIBUTION.—I.

THE suit of the Edison Electric Light Company against Westinghouse, Church, Kerr & Co. for an alleged infringement of Edison's patent of September 19, 1882, No. 264,642, covering the use of feeders in a system of electrical distribution, came up for argument on final hearing before Judge Green in the United States Court, at Trenton, New Jersey, on May 9th. Messrs. S. B. Eaton and F. H. Betts appeared as counsel for the Edison Company, and Messrs. E. Wetmore and L. E. Curtis, for the Westinghouse Electric and Manufacturing Company, the real defendant in the case. The suit was originally brought on December 22, 1886, and alleged an infringement of the patent by reason of the construction and operation of a lighting plant in Trenton, N. J., constructed by Westinghouse, Church, Kerr & Co., during the summer of 1886. Most of the evidence taken in the case has consisted of expert testimony of a somewhat technical character. Among the experts of note who have been employed by the complainant are Prof. C. F. Chandler, and Messrs. H. R. Brevoort and W. J. Jenks. The complainants also took by commission at Glasgow the evidence of Sir William Thomson. The experts for the defence were Prof. Henry Morton, Franklin L. Pope, Benjamin S. Church and others.

The arguments of counsel on both sides have occupied some seven days. The importance of the issue involved is scarcely less than that of the lamp case recently heard in the Circuit Court of Appeals in New York. No small part of the time was necessarily occupied in efforts to instruct the presiding judge as to the force and effect of the technical term employed in the patent, and the scientific matters which are presumably so familiar to readers of this journal that it is scarcely necessary to occupy space in attempting to give a synopsis of the arguments. We have therefore attempted to summarize the leading points upon which the counsel for the complainant and defendant seemed to have principally relied in the presentation of the case in order that its merits may be understood. Certain preliminary questions were brought up by a motion to dismiss the bill which had reference to the capacity of the parties and the jurisdiction of the court, but as these have really nothing to do with the merits of the case, we shall make no further reference to them.

The general purpose of the invention as stated in the specification is as follows:

> "This invention relates to a method of equalizing the tension or pressure of a current through an entire system of electric lighting or other translation of electric force, preventing what is ordinarily known as a drop in those portions of the system the more remote from the central station."

The specification then describes the arrangement and construction of the conductors by means of which the patentee proposes to obviate this difficulty and which constitutes the invention sought to be patented. This will be understood sufficiently from the following passage in the specification:

> "To obviate the difficulty, I provide feeding conductors which extend from the generator or generators to the main conductors of the lamp or consumption circuit or circuits, such feeding conductors not having any translating devices connected therewith, and being connected with the main conductors of the consumption circuit or circuits at the centre, ends or other points on such main conductors."

The specification states in substance that the circuit consists of two essential parts, first the feeding conductors, and second the main conductor of the consumption circuit. This will be recognized as the usual arrangement of feeders and mains in all systems of electrical distribution, in which the conductors radiate from a central station and serve a district of any considerable size. The claims of the patent which are alleged to be infringed by the defendants are as follows:

> 1. A consumption circuit, in the main conductors of which the drop in tension is not sufficient to vary practically the candle power of the lamps connected therewith, in combination with feeding conductors connecting the consumption circuit with the source of electrical energy, and having no translating devices connected therewith, the drop in tension upon such feeding conductors not affecting the relative candle-power of the lamps of the consumption circuit, substantially as set forth.
>
> 2. A consumption circuit in the main conductors of which there is a definite small drop in tension not sufficient to vary practically the candle power of the lamps connected therewith in combination with feeding conductors and having no translating devices connected therewith, the loss upon such feeding conductors being greater than upon the main conductors of the consumption circuit, substantially as set forth.
>
> 3. The combination of a consumption circuit, in the main conductors of which the drop in tension is not sufficient to vary practically the candle power of the lamps connected therewith, with a feeding circuit having no translating devices, and extending from the source of electrical energy to the centre of the consumption circuit, substantially as set forth.

THE COMPLAINANT'S CASE.

Ten or twelve years ago, says the complainant, *i. e.*, in 1879–80, domestic electric lighting was an achievement long sought and ardently hoped for but theretofore unattained. To-day every important town in this and other countries is equipped with thousands of incandescent lamps, in shops, public buildings and dwelling houses, all supplied from a common source. Some mind or minds, some one's ingenuity, or skill, or enterprise, has wrought this change. The problem which had to be solved was one which, twelve years ago, was popularly known as "subdivision of the electric light." It was a different problem from that of the production of a single light from a source of electric energy. It would be too much to contend that this achievement is wholly due to any one invention, or to any one man, but the present invention was at least a notable contribution to the solution of the problem. There were inherent difficulties in both the series and multiple arc system, when applied to extensive distribution to a number of lamps. In 1879 the whole subject of electric lighting had been examined with care by a Parliamentary Commission of Great Britain, at which time the evidence of many prominent scientists served to give some idea of the nature of the difficulties to be encountered. Mr. Edison's plan of using the high resistance lamp with a platinum filament, and of distributing current through it by branches radiating from a common trunk, was known as early as 1879. On January 27, 1880, he patented his carbon filament lamp. He described the general features of his intended system of distribution in an application filed August 9, 1880, and patented March 22, 1881. The present invention is outlined in a caveat filed August 19, 1879, and disclosed in the application for the patent in suit filed August 9, 1880. The difficulties in the way of dealing successfully with electrical energy under the conditions involved in wide distribution arises from the fact that all conductors offer some resistance to the propagation of electric energy, and this resistance occasions the change of electric into heat energy. This conversion takes place throughout any system, but is only useful at the particular points where heat and light are to be made useful and sensible; everywhere else the conversion, though inevitable, is useless, and hence an absolute loss. The problem, as seen by Mr. Edison, therefore was: (1) to concentrate and localize as much as possible the operation of lowering the potential at points where, if useless, it would not affect anywhere the quality of work to be done, and if useful, it would be utilized; and (2) as far as possible to prevent its occurrence in other parts of the system. The ideal mode, theoretically, would be to have conductors of infinite size except at points where obstruction is desired for the production of heat and light; but this is not a feasible remedy, because the cross-sectional area of conductors would necessarily be so large as to involve a prohibitory expense. Moreover, if the whole system be an extended one, and be utilized for consumption throughout, and unless the conductors be so large that no loss in tension ever occurs (which is impracticable) then it is obvious that a variable drop in tension due to variations in the amount of energy translated, will affect very differently, at different times, different lamps in the system. Now Mr. Edison reasoned that if economy of copper is not practiced between any lamps, but only in such parts of the conductors as do not affect the relative candle power of the lamps, then distances may be reached with economy of copper, which are otherwise inaccessible.

The field of the present invention lies between two classes or systems of distribution; one where drop in tension need not be practically considered at all, and the other where the system is so extensive that the size of conductors required to supply it with equal pressures throughout would have to be approximately infinite.

Comparing the second and third, with the first claim of the patent the latter are subordinate in character to the former and introduce special features of construction included under, although not required by, it. The second claim requires a definite small drop in the consumption circuit, and that the drop on the feeder shall exceed that of the consumption circuit. The third claim requires the connection at the feeders to be at a central point on the consumption circuit. The system described and claimed in the patent, is an extended system of electric incandescent multiple-arc lighting, of such dimensions that the distances between the lamps prohibit their supply from one end of a direct circuit, because the drop in tension or the amount of copper required between the lamps would be too great, and also one in which, for purposes of maintaining equal potential at the terminals of all the lamps and notwithstanding the existence of excessive drop in the tension in the system as a whole, that drop is localized where it does not affect the lamps. These characteristics of the Edison system of distribution involve essential characteristics of novelty and are believed to have required the exercise of the inventive faculty for their original production. That the invention is one of great utility is conceded on all hands. The system of the patent in suit was the first practical central station system ever constructed in the world. It was embodied in the New York installation, commenced in the fall of 1881 and opened for operation September 4, 1882, orginally calculated to supply 16,000 lamps. The drop in tension was calculated to be about 15 per cent. on the feeders, and not to exceed 3 per cent. on the mains.

The bill charges that the erection of the infringing central station plant by the defendant was done not only in defiance of the patents of the complainant company, but by taking from the employ of the complainant, and making use of the services of, many employés and experts, whom the complainant had trained in the construction and operation of such plants. When complainant's original *prima-facie* case was a closed in January, 1890, complainant relied upon having proved infringement of the first and third claims, and this was admitted by defendant's experts. Facts were subsequently proved which tended to show beyond question that all three of the claims had been infringed.

The Supreme Court of the United States has commented upon the impossibility of making any satisfactory definition of what constitutes invention. A goal is to be reached, and keen eyes peer in every direction through the mists of surrounding ignorance and uncertainty for any signs of approach to, or the direction of, such goal. He who under such circumstances notably excels his fellows in speed, or who, stepping out of the supposed line of journey, first perceives that it is to be reached by a new, even if only slightly divergent, road, and who thereupon points out the right way, is, in a true sense, an inventor who has promoted the progress of the useful arts. The existing difficulties of the situation, actual or supposed; the mists of ignorance, error or prejudice then obscuring the vision, are to be taken into account in determining whether or not his finding of the true path was only what every one might have done if called upon. In this characteristic of the seeming obviousness of the greatest inventions when once made, they do but resemble the deepest revelations of mental consciousness; as soon as they are stated they are seen to be so obviously true that it is a matter of wonderment that they had not been stated before. In the present instance the problem was not merely that of conveying electricity to a distance and there causing it to be converted into many lights; it was rather to reach and properly supply all parts of a multiple-arc system, some lamps of which were so remote and others so near, that the whole could not be supplied in a direct circuit, and morever to do this without sacrificing substantial equality of potential, and without exceeding practical limits of cost. The remedy lay in a perception of the fact that the distribution could not be practically accomplished without dividing the circuit into two parts.

The question now presented, is whether in the years 1879–80 the means of attainment devised and pointed out by Edison were obvious. A person skilled in the art, at a given time, is perhaps in law presumed to have knowledge of all that had been publicly done in that art up to that time (though as a matter of fact no person with such universal knowledge ever does exist), but it does not follow, therefore, that the law presumes that even persons with the supposed knowledge of all that had been done, necessarily could know what is really true, or what is really erroneous, or could so infallibly distinguish between the true and the false as to be able to combine only what is true, and the best of what is true, so as to produce the highest and best results. Mr. Pope, the defendant's expert, admits that he knows of no patent or publication, prior to August, 1880, which points out the necessity or desirability of locating any drop of tension in excess of a negligible amount, in that part of a system of conductors nearest the generator, and having no lamps connected therewith.

The different prior publications, patents and uses set up as specific defenses are next to be considered. The diagram of Werdermann's British patent, No. 2477 of 1878, was perhaps an attempt to deal with the problem of simultaneously supplying a number of lamps under such conditiens that they would burn at equal candle power. The arrangement is what is known as "reversed parallel," because the position of the return conductor with reference to the first and last bridges is reversed from its position in simple parallel. Werdermann's diagram, which is intended to represent an extended system of distribution, clearly contains no division of the system into feeders and consumption mains, and it is also to be noted that his lamp is not an incandescent lamp. His proposed remedy was, not to limit the consumption circuit to dimensions on which the drop in tension was negligible, nor to divide a large system by points of feeding so that the drop in tension in each part should be negligible, but it was rather the fallacy of creating "equal electrical distances" to each lamp and to enable any sized consumption conductors to be used. Nor was it his idea to use feeders freed from any and all connection of lamps and translating devices. Khotinsky's French patent, No. 107,307 of 1875, was before the Patent Office on the grant of the patent in suit, and was then overruled as a reference. The drawings illustrate an ordinary multiple-arc circuit, supplied at different points by a machine. There is no intimation in the patent that the inventor contemplated any plan of dealing with the difficulties of drop of tension in an extended system; nor that the connections from the machine to the lamp circuit were anything more than the ordinary connections from a machine to a circuit in close proximity therewith; nor that any economy in construction was made possible; nor that any regulation of current with varying numbers of lamps could be facilitated. It gives no consideration or direction which teaches any one how to maintain uniform candle power, or uniform pressure, in an extended circuit. The courts have repeatedly held, that a prior description, in order to invalidate a patent, must be such as to show that the article described in the patent can certainly be arrived at by following the prior description. The general statements of the defendant's experts as to the similarity of the Khotinsky arrangement of circuits to that of the patent in suit, and to the effect that the details of construction specified by the patent in suit would be understood from Khotinsky's patent by those skilled in the art, are abundantly controverted by the evidence of the complainant's experts. Sir William Thomson says, that Khotinsky "does not suggest anything towards the illumination of towns, or the carrying of the electrical energy to considerable distances. He does not contemplate any difference of pressure in different parts of the circuit; there is certainly nothing in any part of his patent which gives any indication towards the solution of the problem discovered by Edison." The testimony of Prof. Chandler and Mr. Jenks is to the same effect. In the British patents of Lane-Fox, Nos. 3988 and 4626 of 1878, and his letter to the London *Times* of December 26, 1878, as expressly admitted by Mr. Pope, defendant's expert, he does not point out any specific arrangement for accomplishing equalization, but merely says that it is to be done by properly arranging and proportioning the conductors. There is in the Lane-Fox patent no scheme for a division of the system of conductors into two parts, one for supplying and regulating the current, and the other for consumption, and the connection of the supply circuit, and the proportioning of the consumption circuit in such a way that there shall be only a negligible drop in tension on the consumption portion. On the contrary, his idea was to use the whole system for consumption, and while probably aware that this would involve a ruinous expense for copper, yet he saw no remedy for that difficulty except that of placing local regulators at each branch, or introducing storage batteries at distant points, and by using an earth return, all of which devices have proven to be wholly impracticable.

The publication in the *Scientific American*, in 1877, illustrates an electroplating apparatus described by Weston as an ordinary electroplating bath. None of the distinguished scientists examined before the British Parliamentary Commission of 1879, appear to have supposed that the secret of proper electrical distribution lay hidden in the every-day practice of an electroplating bath. The analogies to the operation of an electric lamp are so distant, and the structures, consisting of soluble anode, liquid electrolyte, and temporarily inserted cathode, are so totally unlike anything existing in the incandescent lighting art, as to destroy any possibility of treating this compound apparatus as the equivalent of an electric lighting plant. Sir William Thomson says that "there is absolutely nothing in common in the two cases between the respective difficulties and the respective arrangements for overcoming them."

The proof in regard to the use, in distributing systems of gas and water, of what are known as "independent mains," is comprised in a number of early publications and oral evidence in regard to a number of early plants. It may all be summed up briefly, by saying that it appears that for half a century it has been the custom to lead "independent mains" from reservoirs of gas and water to distant consumers, and in some instances to assist overloaded systems by carrying pipes from the reservoirs directly to overloaded points with a view of supplementing the supply at such points. The proposition of the defendant is understood to be, that the known analogies between the laws which govern the flow of fluids and those which govern the so-called flow of electricity, are such that an electrical engineer, in 1880, by the exercise of ordinary skill and knowledge, would necessarily have distributed electricity by a division of the system into consumption and feeder circuits, by proportioning the consumption circuit so that the drop in tension between the several lamps would be negligible, and by bringing the total amount of copper in the system within practical limits, by localizing on the feeders whatever drop in tension was necessary to be incurred to accomplish such economy. The complainant's experts on the other hand contend that the problem was essentially different in the two cases; that the difference between the ponderable bodies known as gas and water and the imponderable something, which we call electricity, are radical; that the laws governing the so-called flow of electricity are different from those governing the flow of gas and water; that the surrounding and interfering conditions are widely dissimilar; that the characters of the conducting systems are unlike, in that one requires only an outflow system, while the other requires an outgoing and return system; that the conditions of economy are very unlike as between hollow pipes and solid conducting wires; and that the incandescent lamp bears no analogy to any device for allowing the consumption of gas or water; hence that the rough analogies which exist between the two systems were not sufficient to teach the electrical engineer that the idea of the so-called "independent main" could be transferred to and adapted to a system of electrical distribution, or that the desired problem of distributing electricity so as to maintain equality of candle power throughout an extended system, with reasonable economy in the cost of conductor, could thereby, or otherwise, be solved. The opinions of the defendant's experts as to the teaching analogies of gas and water distribution, and their effect in vitiating the novelty of Mr. Edison's invention are stated by President Morton and Mr. Pope, but on the other hand the testimony of the witnesses for the complainant, Sir William Thomson, Prof. Chandler, and Messrs. Brevoort and

Jenks, is specifically to the contrary, and the reasons given seem to be satisfactory and conclusive.

The complainant contends that Mr. Edison was the first to deal with an extensive system of distribution, so as to secure uniformity of operation throughout, by the mere arrangement and proportioning of the conductors; the first to establish as the standard of uniformity of pressure on such circuits, the maintenance of equal candle power; the first to supply circuits located at a distance by means of conductors set apart for supplying regulation only; the first to teach how loss of force in reaching distant points with economy could be endured without impairing equality of force where it was to be utilized; and the first to provide a system by which not only uniformity of candle power or pressure could be produced over an extended area, but such uniformity could be maintained under all variations of consumption, because the loss, whether constant or variable, did not affect the consumption.

It is contended by defendant that the patent is void because it covers a necessary and inevitable mode of construction which would naturally be adopted in supplying a small building with electricity from a distant source. This argument sounds plausible, but it is not sound; no one did in fact, prior to 1880, construct any such system. Why should the idea of using the lamps in multiple arc arrangement, and the further idea of supplying such an arrangement from a distant generator, necessarily occur in connection with each other? It requires the connection of those two ideas to make the imaginary case of the defendant. But even if this combination of ideas had actually been made, or such small installation had been actually set up, it is clear that it would have been done without any thought of any problem having thereby been solved of the distribution of electricity over large areas.

It is contended that this invention is a mere matter of engineering and would naturally occur to any engineer. Are not all inventions the result of the working of the law of supply and demand, which, when an invention is needed, stimulates trained minds to work it out? Is not an inventor one who merely hastens the inevitable evolution of thought? The courts have often said that an invention may be made in a flash, but they have never said that it must be so made, or that it may not be made as the result of a thorough and intelligent working out of a problem. The final perfection of all improvements is often removed by only a short space from previous impracticable contrivances. In this, as in all other things, as the proverb says, "Perfection lies in little things, but perfection itself is not a little thing." It is the finishing stroke that counts. The Supreme Court has said "In the law of patents it is the last step that wins."

The defendant contends that the application for a patent, as originally filed, does not contain the invention as now defined; but this is an error. The drawings are the same as those found in the patent as granted, except that some figures have been erased, and the claims originally filed, though more general in phraseology than those now sued on, evidently include the same subject-matter. The effect of the amendment to the specification in its progress through the Patent Office, was merely to eliminate objections based on the generality of the language first used, but not in any way to alter the character of the invention.

It is submitted, therefore, that the feeder and main invention of Edison, was one involving invention of a high class; that it was not anticipated by any constructor, nor found described in any prior patent or publication; that it is clearly infringed as to the first three claims; and that complainant is entitled to a decree.

THE EDISON INCANDESCENT LAMP PATENT—FINAL HEARING BEFORE THE U. S. CIRCUIT COURT OF APPEALS.—II.

ON April 26, General Duncan resumed his argument. He pointed out that whether arranged in series or in multiple arc, the law was true of all translating devices, that the law of high resistance in each individual transmitting device must be observed. He then showed that when lamps were arranged in multiple arc, there might be conditions which required the lamps in one plant to have higher resistance than those in another; in some commercial lamps, the resistance was certainly fifty or sixty times, if not 100 times as great as in others, yet the same law applied equally to them all, viz.:—A high resistance in the translating devices as compared to other parts of the circuit. It seemed to him that there could be no other signification attached to the expression of "high total resistance" in this whole discussion. It would not do to say that a burner had high resistance merely because it happened to be higher than that of some other burner. That was not the test; if that test were to be applied somebody to-day might make a burner of higher resistance than Mr. Edison made yesterday, and then Mr. Edison's burner would become one of low resistance. The root of this matter of high resistance was beyond any such attempted definition, and the explanation lay in the direction he had indicated. Another feature to which he desired to call attention was that the carbon of the modern incandescent lamp was subject to continual deterioration, whether it was called disintegration, evaporation, volatilization, or any other name; from the time a lamp went into service its efficiency continued to run down until its life was gone. The record showed that manufacturers did not care to guarantee a life of more than 600 hours. What was the significance of that fact? There, said General Duncan, pointing to a diagram, are curves plotted from observations by a committee of the Franklin Institute in 1884. Twenty Edison lamps had been tested for 1,000 hours. The curve of candle power showed at the beginning an average of 18.6, gradually decreasing until at the end of the thousand hours it had fallen below 12 candles, a loss of over 33 per cent. Another curve showed that the average resistance of the lamps at the beginning was 136 ohms, while at the end they had risen to 148, some ten or twelve ohms. Now what did those curves signify? This, that in the progress of the tests a change was going on in the carbon. There was less light given off, and there was a disintegration of the carbon whereby its cross-section was diminished, its resistance increased, and the detached particles of carbon were deposited upon the globe producing the blackening which their honors might perhaps have observed in incandescent lamps. There was a disintegration of carbon going on with a consequent loss in illuminating power. It was a gradual process, but a necessary concomitant of the incandescent lamp as made by all manufacturers. Other published tests made by Mr. Fousshe and by Dr. Siemens, were cited in which similar results had been shown. These various pieces of evidence warranted him in asserting that there was no such thing as "absolute stability" of the carbon of incandescent lamps. He used that term advisedly, because Mr. Edison had claimed to have made such a discovery, and had said in his testimony that with great deliberation he had written into his patent, that carbon was absolutely stable when introduced into an all-glass globe from which air and all other gases had been exhausted. Now, he, (General Duncan) contended that there was no such thing as "absolute stability." The stability of carbon in a lamp was a mere relative term. No man had even yet reached that point where he was justified in claiming that he had discovered a method whereby it could probably be made absolutely stable. He ventured to say that this observation would ultimately be found to have an important bearing upon the merits of the controversy. He then referred to a later patent of Edison, in which, giving the public the benefit of his larger and riper experience, he had said that too high a vacuum must not be used, or the carbon would disintegrate too rapidly, and the life of the lamp would be too short.

General Duncan said he would next ask their honors' attention to the patent in suit. Handing to the court a lamp which plaintiff asserted to be a copy of the Patent Office model, he called attention to the fact that the burner, presumably of carbon, was coiled into a spiral. The contact between the burner and the leading-in wires was by means of a cement, moulded around the junction and carbonized in position. He would first invite attention to the second and third claims of the patent. The second claim was for "the combination of"—as it reads—"carbon filaments," (it should read undoubtedly a carbon filament) "with a receiver made entirely of glass, and conductors passing through the glass and from which receiver the air is exhausted for the purposes set forth." The third claim was for "a carbon filament or strip coiled and connected to the electric conductors, so that only a portion of the surface of such carbon conductors shall be disposed for radiating light as set forth." Their honors would notice that the term filament, a pivotal term in the patent and in the whole discussion, was singularly enough a term never known in the art until employed in this patent. Yet the patent contained no attempted definition of the term itself. Notwithstanding the requirement of the law, that in order to secure a valid patent a full, clear and concise description must be given, and the distinction pointed out between the invention and what had gone before, this gentleman had gone to the Patent Office and had used a term, a pivotal term in the patent, absolutely new to the art, and had given no definition of it; had left defendants to guess its meaning if it were possible to do so; had left them in a state of uncertainty that did not enable them to determine what were the respective rights of the parties; what ground had been covered, and what had been left open for the world to occupy without molestation. It was a most significant fact that the definitions of the term which had been given were as numerous as the judges who had undertaken to define it. But notwithstanding it was a new term in the art it had been universally adopted, not only in the shops but in the literature of the art, and whether the burner was the five-thousandth of an inch, or twenty times that diameter, they were all called "filaments" in the popular sense. Examining the text of the specification, he found many other terms employed by Mr. Edison to designate the burner of his lamp; he had referred to it as a "strip"; as "wire or sheet"; as "conductors" and in another place as "threads." He supposed gentlemen upon the other side would contend that the employment of these numerous terms ought to serve as a guide to determine the meaning of the word filament in the claim, but to which one of those terms could they go? Notwithstanding the uncertainty in which the nature of the invention had been left by Mr. Edison by the use of this ambiguous, undefined and novel term, he thought it possible to determine that whatever else it might mean, it had certain limitations imposed upon it, by which plaintiff must be bound. The thing called in claim 2 a "filament" was a burner that must be coiled into a spiral. It was a device whose resistance, when in working order, must be at least 100 ohms, else it could not perform the duty assumed to be put upon the lamp which was the subject of the invention. He thought it also imported a carbon having a high specific resistance due to carbonization pure and simple without any reduction arising from subsequent treatment. Analyzing the language of the claims, General Duncan contended that claim 3 was for a peculiar form of burner, irrespective of the globe in which it was placed, while claim 2 was narrower, and was for putting the burner of claim 3 into a globe entirely of glass from which the air had been exhausted. He then proceeded to show that the method of producing high resistance and still keeping down the radiating surface, was by coiling the conductors. If Mr. Edison had known at the time he made his invention how to manipulate carbon as well as he knows to-day it might not have been necessary to introduce this limitation. The art had progressed wonderfully since October 1st, 1879, and there were to-day processes by which high resistance burners could be secured without resorting to that method, but that was not what Mr. Edison had explained to the world in this patent. He believed Mr. Edison had worked intelligently on that line. He had found it necessary to coil the carbon to secure that high degree of resistance necessary to make the lamp serve in large numbers in multiple arc. He had found that coiling would be conducive to steadiness in the light, and to economy in the operation of the lamps, and then he had come in and said: "My invention consists first, in the burner which is coiled, and secondly,"—the principal thing in controversy herein —"in putting such a burner into a particularly constructed exhausted globe," and he would say here, if that be the construction of the claim, no injunction could go against the defendant. Defendant's burner was not coiled; nor could it have been used in large numbers in multiple arc, with any method of distribution of current known to the art at the date of its issue. He should have occasion later on to refer to an application filed in the Patent Office just after the issue of the patent now before the court. A controversy arose in the Patent Office as to the nature of the invention covered by the patent in suit. It had been found necessary to draw a distinction between the invention of the patent in suit and the invention covered by the then pending application, in order that Mr. Edison might secure, through the medium of that pending application, a broad claim such as plaintiff asserted to be the proper interpretation of the patent which they had brought into court. Furthermore, a month and a half after he had filed the application of the patent in suit, they found Mr. Edison filing a caveat in which he had given an exposition of the philosophy of coiling the burner, and had insisted that coiling was a necessary means for securing that conjunction of high resistance with small radiating surface necessary for the distribution of lamps in large numbers in multiple arc. Whatever, therefore, Mr. Edison may have discovered at a date later than November 4, 1879, when he made application for this patent, he certainly at that time regarded the coiling of the burner as a *sine qua non;* he had not only said in terms in claim 3 that it was to be "coiled," but in laying the foundation of claim 2 he had said the invention had consisted in putting such a burner into a globe of a certain character. Now he (General Duncan) conceived it to have been one of the fundamental errors made by the circuit court; that of refusing to find that coiling was a constituent of the second claim. The learned judge had said that coiling was only an alternative form, and not a constituent of the second claim, but the reason which had been assigned for the support did not support that conclusion. The court had said: "It may be that in the haste which has always seemed to characterize Mr. Edison's efforts to patent every improvement, real or imaginary, which he has made or hoped to make"—which he thought a very excellent characterization of Mr. Edison's methods of patenting supposed inventions—"he had not stopped to reflect, when he framed his application for the patent, that the filamentary burner would do its work just as well uncoiled as coiled, provided the same length and cross-section were used." The fact was, a burner would *not* do its work just as well uncoiled as coiled, provided the same length and cross-section were used. It was impossible that it should be so, yet that was the reason Judge Wallace had given for finding that coiling was not a constituent of the second claim? If his honor had understood that point would it not have been logically necessary for him to have concluded that the coiling was a constituent of the second claim; and therefore that the defendant was free? Another limitation which defendants thought must necessarily result in claim 2, was that the thing called therein a "filament" was a burner having a resistance of not less than 100 ohms when heated by the passage of the current. An analysis of the patent showed that Mr. Edison's idea was to organize a lamp that would allow a practical subdivision of the electric light. He had criticised the older lamps because of their low resistance, and had said that for this reason they could not be used economically in great numbers in multiple arc. He proposed to employ a filament of carbon, which might he so used. He had not told us what a filament was, but they had learned from the patent itself that the thing he had been talking about by this unknown term was something having a very high resistance; high enough to permit a large number to be used in multiple arc. How high must that be? If the patent did not tell them, they had a right to go to the contemporaneous utterances of the man who made the invention. The lowest resistance mentioned in the patent in connection with the curious term "filament" was 100 ohms. Did he intend that to be the lowest limit? They thought it was. Mr. Edison had testified in 1881, referring to certain experiments just about the time this invention had been made: "What we desired at that date, and had concluded as the only possible solution of the subdivision of the electric light was that the lamp must have a high resistance, and small radiating service, so as to be capable of working in multiple arc commercially, and our calculation showed us that lamps must have at least 100 ohms resistance to compete successfully with gas." We find Mr. Edison in other statements declaring again and again that the burners must have at least 100 ohms. Is not that limitation then fairly embodied in this term "filament?" If it be such a limitation upon the second claim then two of the three lamps made by the defendant were not within the claim.

THE OLD SUIT OF THE NEW YORK ELECTRIC LINKS CO. SETTLED.

THE United States Supreme Court has affirmed the judgment by which the Court of Common Pleas of New York refused to grant the New York Electric Lines Company a mandamus to compel Rollin M. Squire, then Commissioner of Public Works of New York City, to give the company a permit to make an excavation in the streets for the purpose of laying underground wires. An act of the New York Legislature authorized the company to construct lines along the public highways, and in April, 1883, the common council of New York gave the company permission to lay its wires through the streets of the city. The company filed a map of its proposed location in accordance with the requirements of the city ordinance, but took no steps toward laying its wires until July, 1886, when it applied to Commission Squire for a permit to make excavations. In the meantime, the act creating the New York Electric Subway Commission had been passed, and to this commission was given authority to approve all plans for underground conduits, and the permit was accordingly refused the New York Electric Lines Company.

The company made the claim that as it had accepted the franchise granted it, the refusal to give it a permit under that act constituted an impairment of the obligation of its contract. The Court, in an opinion by Justice Lamar, read by Justice Blatchford, holds that the contention is not well founded.

Letters to the Editor.

HIGH AND LOW SPEED ENGINES IN RAILWAY WORK.

I HAVE been greatly interested in reading the article by Charles W. Wason, in your issue of April 27, on "Comparative Tests of High and Low Speed Engines in Electric Railway Work." As Mr. Wason says, the difference in coal consumption in favor of low-speed engines is not as great as advocates of this type of engine have been wont to expect and claim; and I would submit, that if the test could be brought to more exact equality of conditions, as regards temperature of the feed water and the evaporative efficiency of the boilers, this comparative difference would be much reduced.

Taking the figures given for the temperature of the feed water, it appears from a calculation of the amount of heat required to raise the total feed water through the range of temperature represented by the difference, that the amount of fuel per electrical horse power would be reduced .25 pound. Had it been possible to secure the same evaporation per pound of coal in each test, the decrease in the amount of fuel per average electrical horse power per hour would have been about 8 per cent., equal to .5 pound of coal. This would make the difference still remaining in favor of the low-speed engines only equal to .43 pound of coal per electrical horse power per hour.

Taking into consideration the increased floor space occupied by low-speed engines and counter-shafting, the greater cost of the installation, the extra belts, bearings and details of apparatus requiring attention, it would appear that the low-speed plant would have little or no advantage, practically, over a plant equipped with first-class high-speed engines directly belted to the generators.

I do not wish to be understood as citicising in any way Mr. Wason's tests, but simply as inviting more favorable consideration of the high-speed engine for this service.

THOS. G. SMITH, JR.

CINCINNATI, OHIO.

THE CONSTRUCTION OF THE LONG-DISTANCE TELEPHONE LINES.

Referring to Mr. Herbert Laws Webb's article in The Electrical Engineer of May 4 and 11, I think that gentleman could add still more interest to his generous contribution of telephonic literature to the technical press by giving some information on the following points, namely:

How is it that conversation can be satisfactorily carried on over a wire from Newark to Boston *via* Pittsburgh, Buffalo and Albany, upwards of a thousand miles in length, having a *K. R.* of over 157,000 for the entire loop, when the rules laid down by Preece and H. R. Kempe state that the *K. R* of a loop divided by 4 should not exceed 10,000 to insure good speaking?

On page 449 is a cut of a long-distance telephone pole, the top end of which is out of sight, and supposed to carry 50 or more wires. What engineering rules are observed as to the length, diameter of base and top for vertical and lateral stresses, including wind pressure on the surface of pole and wires?

Mr. Webb speaks of the wires as being "tautly drawn," but no data is given as to the sags allowed at different temperatures and the ratio between the tension of the wires in coldest weather, and their breaking strain; and what kind of splice has been found to preserve a good electrical contact in all situations and at the same time approach as nearly as possible the normal breaking strength of an unspliced wire?

I cheerfully recognize and applaud all efforts at good substantial work in both the telephone and telegraph field, and believe it is to the interest of the proprietors to have such undertakings carried out under the best engineering rules in the most substantial manner; yet I fear Mr. Webb has allowed his enthusiasm to lead him into an unwarranted belittlement of his neighbors, not quite appropriate to the columns of the technical press. He will no doubt realize this when he reflects upon the miles upon miles of Long-Distance telephone lines that were hopelessly prostrated in January, 1891, in New York, Connecticut and New Jersey, and of the comment it excited at the time among electrical engineers. Even in the streets of New York City, poles fell into people's windows and across the streets in all directions; and yet Mr. Webb tells us that the most thoroughly scientific electrical engineering is exemplified in the most striking manner in the Long-Distance telephone system.

F. W. Jones.

New York, May 11, 1892.

Literature.

Dynamo-Electric Machinery; A Manual for Students of Electrotechnics. By Silvanus P. Thompson, D. Sc., B. A., F. R. S. Fourth edition, enlarged and revised. *New York*, Spon & Chamberlain, 1892. 864 pages. 5½ by 8½, 29 plates. Price $9.00.

We do not go beyond the bounds of conservative estimate when we characterize the "Dynamo-Electric Machinery" of Prof. Thompson as the work, above all others, to which electrical engineers have long looked for a record both of the art and of the theory underlying the construction of such machinery.

Some ten years ago, in his Cantor lectures, delivered before the Society of Arts, Prof. Thompson gave an excellent résumé of the general principles underlying the construction of dynamos, and with this as a basis he subsequently elaborated the work of which we now find before us the fourth edition. It would be, indeed, a work of supererogation to attempt, at this late day, to give a general review of this well-known and universally employed manual, but the volume before us contains much new matter, and has, we are glad to note, been given a thorough overhauling, with the result that it presents a far greater harmony in the treatment of its subject-matter than is to be found in the older editions. We notice particularly that Prof. Thompson, in conformity with the views now generally prevailing among electrical engineers, has drawn less and less distinction between dynamos and motors, in the treatment of the problems involved in their respective designing, and has, on the contrary, treated the subject more particularly from the standpoint of action and reaction between a wire carrying a current and a magnetic field in its neighborhood. Being a work intended more for the practical worker than for the mathematician, the author has wisely so framed it that it may be considered to be an exposé of physical and experimental theory, in contradistinction to the mathematical, but he has not refrained from employing, where necessary, algebraical and graphical methods. Thus, in order to impress at once upon the reader the physical theory of the dynamo, the author brings out as an illustration Fleming's now well-known rule of current flow, represented by the thumb, index and middle finger, and builds up from this the actions which take place when a conductor passes through a magnetic field. Even at this point in the theory the author introduces examples taken from actual machines, so as to impress upon the student the manner of employing the formulas and symbols. He has added much, also, to the chapter on the actions and reactions in the armature, and has given special attention to the cross-magnetizing action which takes place and which is shown very clearly by a number of diagrams illustrating these various actions. Taking all these actions into consideration, the author vouchsafes the statement that the ideal dynamo of the future for constant pressure work will have but one turn of wire to each section; it will have practically no lead at the brushes will not spark, and its internal resistance will be practically nil.

The author then takes up the mathematical action and reaction and furnishes numerous examples and methods of calculation to obtain given currents or torques in dynamos and motors. Magnetic principles and the magnetic properties of iron and magnetic circuits, and the working theory upon which the modern dynamo is based naturally come in for a large share of attention, in which the author has introduced the results of the latest work of Ewing, Hopkinson and others. The application of these researches to actual construction is shown, and we are pleased to see much of the older matter in former editions omitted in the present. The author treats very thoroughly the various forms of field magnets, and then passes on to the elementary theory of the dynamo, and the discussion of the characteristic curves, which leads up naturally to the construction of constant potential machines. The chapter on winding of armatures and the theory of connections is of special interest, as it brings out the special methods employed, including not only the older ring and drum types of winding, but also those of more modern disc types. The succeeding chapter on the mechanical construction of dynamos, the descriptions of constructing the commutators, brushes and brush holders, of attaching the iron core to the spiders or driving flanges, etc., and a variety of other details of like nature all add to the practical value of this part of the work. We notice that among the methods of applying carbon brushes, the author illustrates a practice, evidently of English origin, in which the brushes are said to rake in a direction opposite to the rotation, so that the end pressure may be greater when running. We are not informed as to the manner in which the brushes so set wear, nor as to their noiseless properties—if, indeed, they can be anything but noisy and chattering. The particular brush illustrated is designed for use on the mining motors. Minor mechanical points in the design and construction of dynamos also form the subject of a short and very valuable chapter, in which these details relating to the most successful machines are given.

Perhaps the student, who is looking about for a guide to the application of the rules and formulas laid down, and which form the subject of discussion in many valuable papers in the transactions of electrical societies, will be most interested in the chapter devoted to the elements of dynamo design and calculation of winding. In this the author, with the aid of numerous examples, shows how the formulas are applied to calculate the volts generated in the armature, the current flowing in the armature and field, the gauge of wire for both, the magnetic flux through the armature, the cross-section of iron necessary in both the field and armature, and a variety of kindred points, all requisite to the design of an efficient machine.

Arc lighting dynamos and examples of modern machines of various types then follow. In the latter chapter the author gives a brief description of the Edison dynamo, 1888 type, the one now in general use. The author states that the field magnet is of cast iron. This is an error, as both the magnet cores and the yoke are of wrought iron, the pole-piece alone being of cast iron.

While, as above stated, the subject has been treated from the broad standpoint of action and reaction between armature and field magnet, and thus made to include both the dynamo and the motor, the author has very wisely introduced into his chapter on electric motors much new matter tending to elucidate some of the points which must be considered in the design of electric motors; and the new illustrations introduced will go far towards clearing up the subject in the minds of beginners.

The principles of alternate currents and their application to the modern alternating dynamos form subject matter of Chapter XXII, and this is followed by a chapter on alternate current motors, in which the latest multiphase of rotatory field machines are described and discussed with the aid of excellent diagrams. Alternate current transformers are then taken up by the author and their theory and method of construction described, with special reference to actual examples as exhibited in practical transformers. Regulators for dynamos and the testing of dynamos and motors for efficiency may be considered to end the part relating to the theory and construction; to these the author has added a chapter on the management of dynamos, containg general instructions for their use, and embodying much of the author's famous paper on the "Diseases of Dynamos."

The work throughout is copiously and most uniformly well illustrated, so that the reader gains an accurate knowledge of the machines and principles described. The value of the new work is also enhanced by a large number of plates showing the details of construction of a great variety of new machines all drawn to scale, and thus offering a valuable guide to the designer both of continuous and alternate machinery. In a work of this character, devoted more particularly to the exposé of principles and descriptions of machinery, much can be done by an author to arouse interest in a subject, which would hardly be characterized as popular; but the felicitous style of putting things, for which Prof. Thompson is so well known, will, we are sure, continue to make the work before us in the future, as it has been in the past, not only the most complete but the most popular extant on this subject. If Prof. Thompson had done nothing else, this invaluable book would serve as his enduring monument.

College Notes.

SCHOOL OF MINES, COLUMBIA COLLEGE.

THE two year post-graduate course for the degree of electrical engineer is outlined in the Circular of Information of Columbia College for 1892–3. Candidates must pass entrance examinations in mathematics, mechanics, physics, chemistry, and drawing, and the curriculum provides for very thorough instruction in the general principles and theory of electricity as applied to lighting, the generation of power, telegraphy, telephony, etc. In addition to this the course includes a large amount of mechanical engineering, workshop practice and laboratory work, and closes with the customary thesis upon some special subject assigned.

Society and Club Notes.

FRANKLIN INSTITUTE.

AT the last meeting of the Electrical Section of the Franklin Institute the by-laws were amended so that the regular meetings would occur on the fourth Tuesdays of each month at 8 p. m. excepting in July and August. This month however there will be a meeting on Tuesday, the 31st, at which time papers will be read by Mr. Paul A. M. Winand, Prof. Edwin J. Houston and others.

THE FORMATION OF THE MASSACHUSETTS ASSOCIATION FOR SUPERINTENDENTS OF STREET RAILWAYS.

MR. GEORGE A. MURCH of the Worcester, Leicester & Spencer Electric Railway issued invitations to the various street railways of Massachusetts requesting their attendance at an informal dinner held at the Massasoit Hotel at Spencer, on Tuesday of last week for the purpose of organizing a State association for the superintendents of street railways. The party met together in Salem Square, Worcester, where a special car was awaiting to take them to Spencer. About thirty-five gentlemen were present and a very enjoyable trip was made from Worcester to Leicester where an opportunity was afforded the visitors to visit the new station. This station has been running now for about a year and has been extremely successful. The generators are of the Thomson-Houston type and are operated by a large Corliss engine manufactured by C. J. Cooper & Co., of Mt. Vernon, Ohio, and arrangements are now being made to duplicate this plant. Immediately adjoining the station are situated large, well-ventilated car shops and the whole equipment was eagerly inspected by the visitors. The trip was then continued to Spencer where Mr. Murch had a good dinner provided for the benefit of the guests at the Massasoit Hotel. After dinner there were several interesting speeches by the various members in favor of establishing the association, after which the association was formally organized with the following officers: President, Geo. A. Murch, Leicester; vice-president, B. J. Weeks, Quincy; secretary and treasurer, F. G. L. Henderson, Newton. It was voted that the initiation fee be $5 and that all railroads becoming members be assessed that amount. It was voted that the secretary notify the superintendents of all street railways in the State of the formation of the association. The next meeting will be with B. J. Weeks of Quincy and subject to the call of the secretary.

Mr. George A. Murch, president of the association, has had a large experience in street railways in Salem, Mass., Malden, Mass., and Waterville, Me., and elsewhere. He has a made a success of the road which he now represents and will undoubtedly fill the position of president with energy and care. The following gentlemen were present: Geo. A. Murch, supt. W. L. & S. Street R. R.; H. E. Bradford, supt. Marlboro Street R. R; J. E. Sewell, supt. Woburn street R. R.; N. E. Morton, supt. Merrimac Valley Street R. R.; J. J. Hennesey, supt. Framingham Street R. R.; Wesley Wentworth, supt. East Middlesex St. R. R., Malden; J. E. Bigelow, supt. Worcester & Shrewsbury St R. R.; F. Lanoir, supt. Electric Dept. Worcester Consolidated St. R. R.; H. C. Page, supt. Newburyport & Amesbury St. R. R.; M. A. Carter, supt. Attleboro, No. Attleboro & Wrentham St. R. R.; F. G. L. Henderson, supt. Newton St. R. R.; Hon. Samuel Winslow, supt. Worcester & Millbury St. R. R.; B. J. Weeks, supt. Quincy St. R. R.; S. S. Heywood, Salem St. R. R.; R. Sennete, North Carolina; Chas. Page, Toledo, O.; R. E. Bradford, Providence, R. I.; R. E. Morton, Lawrence; C. E. Smith, Boston; H. J. Newton, Worcester; Edwin Watson, J. B. Gorman, W. S. Whittemore, Leicester; O. A. Freeman, Geo. F. Madison, Spencer.

ELECTRIC TRACTION AT THE PROVIDENCE COMMERCIAL CLUB.

THE influential organization known as the Providence Commercial Club, gave its closing banquet for the season at the Narragansett Hotel, Providence, R. I., on May 14th, when the subject for post-prandial discussion was "The Electric Railway in its Relation to City Life." About 100 of the leading bankers, merchants and manufacturers of the city and vicinity, including Governor-elect Brown, sat down, with president Watson at the head of the table. A paper on the subject-matter was read by Mr. T. C. Martin, and addresses were also made by Mr. H. M. Whitney, president of the West End Road, of Boston; Prof. Elihu Thomson, and Mr. Oscar T. Crosby, the head of the railway department of the Thomson-Houston Co. Mr. Charles A. Coffin, president of the new General Electric Co., was also present and was to have spoken, but had unfortunately to leave by an early train for Boston. Each of the speakers took up the topic from a different standpoint, and the hearty reception given their remarks by this representative audience showed that electric traction has gained the day in Providence. Among those present were Messrs. Phillips and Sawyer, of the American Electrical Works; Mr. Fenner, of the New England Butt Co.; Mr. Marsden J. Perry, of the Narragansett Electric Light Co.; and Mr. White, of the Providence Telephone Co. After the banquet, the speakers of the evening were entertained by President Watson, Secretary Field, and Mr. Gardiner C. Sims, at the Hope Club.

ELECTRIC RAILWAY WORK IN BROOKLYN.

THE ATLANTIC AVENUE RAILROAD COMPANY, of Brooklyn, is rapidly pushing forward the preliminary work of electrical construction. The power station will be located on the Gowanus Canal, between First and Second streets, and will cover an entire block. There will be a frontage on the canal of 200 feet, and 630 feet on a lateral basin. The boiler equipment will consist of three batteries of Babcock & Wilcox boilers, each battery comprising two 250 h. p. boilers. Each boiler will be 23 feet long, the tubes will be one-eighth inch thick, and will rest on extra heavy shelves. Four Corliss tandem compound condensing engines have been ordered; one of 350 h. p. and three of 500 h. p.; which latter will be adopted as the unit for future work; the station having been designed for an ultimate capacity of 5,000 h. p. The fly-wheel of the largest engine will be 60,000 lbs. weight. One condenser and two air pumps have also been ordered, to be run by a smaller engine. Three different kinds of rail are to be laid; that manufactured by the Lewis & Fowler Girder Rail Co., Duplex Street Railway Track Co. and the Pennsylvania Steel Co. Samson bridge joints, made by the Tramway Rail Co., of Pittsburgh, will be used with the last-named rail. Ties will be laid 30 inches between centres, of 5 x 9 Florida yellow pine and Connecticut white oak.

The tubular style of poles, with shrunk rings at each joint, will be used; mainly 28 feet long. They will be furnished by Wallace & Co., of New York. Most of the overhead construction will be of span wires; an exception being made as to part of Ninth avenue, where the poles will be placed on one side of the street, with a 15-foot bracket extending over both tracks. This is practicable at this point, as the tracks are not in the centre of the street, but more to one side.

An order has been given for 50 cars, to be furnished by the St. Louis Car Co. They will be 27 feet in length; the body being 18 feet 6 inches. They will be finished inside with mahogany and three-ply bird's-eye maple, with beveled-edge mirrors and bronze trimmings. Peckham's flexible, non-oscillating motor trucks No. 4 B will be used. It is expected that a portion of the road will be in operation early in July. The first motor equipment will consist of 100 30 h. p. Westinghouse motors—single reduction The company have also ordered two 400 h. p. generators and two 700 h. p. generators (Westinghouse) making a total of 2,200 h. p.

A MASTER ELECTRICIAN FOR THE N. Y. NAVY YARD.

A PRELIMINARY examination is to be held at the New York Navy Yard, on May 31, for filling the new position of master electrician in the Equipment Department. The salary is to be $6 per day. The position is open to all comers who are citizens of the United States, and is one requiring ability to lay out work and to get it done. Applications should be addressed to the Commandant, Navy Yard, New York, not later than May 28.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MAY 3, 1892.

Alarms and Signals :—

Electrical Annunciator, F. W. Steeg, 473,975. Filed Oct. 24, 1890.

Enables an indicator whose position has been changed by a call to be restored to normal position by itself without interfering with any other indicators.

Station-Indicator, J. H. Dean, 474,001. Filed Dec. 21, 1891.

Has for its object to provide a reliable and automatic indicator for electric street railways which will operate positively and will not get out of order.

Conductors, Conduits and Insulators :—

Insulator, O. F. Goodrich, 474,319. Filed Dec. 29, 1891.

Comprises a body portion of insulating material and two staples having their ends embedded within the insulating body and their loop portion extending from the outside.

Distribution:—

System of Electrical Distribution, W. H. Elkins, 474,166. Filed July 11, 1891.

Employs a plurality of independent circuits each comprising armature coils connected with the adjacent coils and adjacent segments of the commutator and which are common to all the circuits as the armature revolves but wholly in one circuit while operating.

Dynamos and Motors:—

Apparatus for Maintaining Constant Speed in Motor Mechanisms, J. W. Gibboney, 474,008. Filed Sept. 25, 1890.

Consists in providing mechanisms to be controlled with an electric retarding device in which the energy consumed is varied by controlling its breaking effect in correspondence with the driving power required.

Regulator for Dynamos and Motors, W. H. Elkins, 474,165. Filed Feb. 6, 1890.

Employs three sets of commutator brushes placed at successive points around the commutator, the intermediate sets being fixed and the other two movable, and automatic mechanism for lifting the latter.

Electrical Motor Mechanism, S. E. Mower, 474,328. Filed May 21, 1891.

Employs a gearing of sprocket wheels and chains.

Lamps and Appurtenances :—

Electric Arc Lamp, C. A. Pfluger, 473,955. Filed July 16, 1890.

Employs two distinct gravity clutches, a main circuit magnet working solely upon one clutch, a stop to throw it out of operation, and a derived circuit magnet to actuate the other clutch and regulate the arc.

Electric Arc Lamp, C. A. Pfluger, 473,956. Filed Nov. 13, 1890.

Provides convenient means for conducting the current to the upper carbon and for cutting out the lamp.

Electric Lamp Hanger, E. Dills, 474,003. Filed Sept. 8, 1891.

Consists of a spring-actuated drum having a flexible cord wound upon it and acting in the same manner as a Hartshorn shade roller.

Electric Arc Lamp, W. B. Luce, 474,091. Filed Aug. 8, 1891.

Employs a single magnet to effect the double purpose of a lifting and a field magnet.

Electric Arc Lamp, A. L. Shepard, 474,266. Filed Aug. 6, 1891.

A lamp whose regulation is controlled by coils in series with its arcs so that while keeping the current constant it will absorb any excess of potential or compensate for diminution of potential below the normal.

Miscellaneous :—

Solenoid and its Electrical Connections, H. H. Hosford, 473,929. Filed June 3, 1891.

Provides means for shifting the position of the magnetic poles of a solenoid without making and breaking the energizing current and without injurious sparking at the contact points.

Electric Clock Motor, A. Reckenzaun, 473,960. Filed Dec. 16, 1889.

Has for its object to produce constant motion upon a spindle and to eliminate sparking at points of contact.

Electric Resistance Box, A. Wirsching, 474,073. Filed Mar. 18, 1891.

Employs two frames having the inner faces provided with guideways, spacing blocks of insulating material, fitting into the guideways, and a wire wound in spiral layers between the spacing blocks.

Heat-Regulating Device, A. B. Morse, 474,139. Filed Apr. 21, 1891.

A thermostat having a contact arm moving between two contacts controlling the regulating mechanism and having a safety contact also in circuit with said mechanism.

Thermostat, A. B. Morse, 474,140. Filed Apr. 28, 1891.

Similar to No. 474,139.

Thermostat, L. G. Rowand, 474,149. Filed Oct. 7, 1891.

Employs a fusible solder adapted to allow contact to be made when a certain temperature is reached, thus closing the circuit and sounding an alarm.

Regulating Propellers of Vessels, A. Hellinger, 474,169. Filed Jan. 16, 1891.

An electrical marine engine governor.

Torpedo Launching Apparatus, J. B. G. A. Canet, 474,291. Filed June 9, 1891.

An electric firing mechanism for torpedo launches, etc.

Railways and Appliances:—

System of Electrical Conductors, C. J. Kintner, 473,932. Filed Apr. 18, 1890.

Employs tubular archways of conducting material electrically connected to earth in combination with a concentric conductor whose outer wires are electrically connected to the archways.

Modes of Arresting Electric Locomotives, S. H. Short, 474,031. Filed March 10, 1891.

Provides means of checking the speed of electric cars without employing the current from the trolley line. See THE ELECTRICAL ENGINEER, May 11.

Trolley Wire Circuit Breaker, J. M. Andersen, 474,037. Filed Nov. 11, 1891.

Consists of a non-conducting body having circuit terminals attached near its ends and an independent conductor attached to the non-conducting body and out of contact with the circuit terminals.

Insulating Support for Electric Railway Wires, A. A. Shobe and W. Embley, 474,049. Filed Oct. 29, 1891.

A jointless conductor in which the several lengths of wire are united end to end by being brazed, soldered or fused instead of being united by sliding joints.

Conduit Trolley, J. J. Cosgrove, 474,218. Filed June 3, 1891.

A trolley that may be easily adjusted vertically in order to pass any obstruction.

Bicycle Electric Car, E. M. Boynton, 474,331. Filed April 20, 1891.

A car suspended from the motor and entirely independent of it so that the motor may perform the slight undulations inseparable from running on any kind of road without imparting its motion to the car.

Switches and Cut-Outs :—

Electric Switch, J. J. Wood, 474,050. Filed Nov. 3, 1891.

A quick-break switch intended to reduce the flashing to a minimum and render the cut-out absolute.

Telephones and Apparatus:—

Telephone-Exchange Apparatus, J. J. Carty, 473,911. Filed Nov. 25, 1889.

Requires no generators at the subscribers' stations and no individual annunciators at the central office.

Telephone Switch, C. E. Scribner, 473,966. Filed Aug. 19, 1884.

Provides means whereby the bells of any two subscribers may be shunted and their telephones brought into circuit automatically by the operator at the central office as he connects the lines.

House Telephone System, C. E. Scribner, 474,067. Filed Nov. 22, 1889.

Relates to metallic circuits and apparatus for house telephone work and to a battery having each of its poles carried to each of the different stations and so arranged that one station may signal to any other.

Telephone Receiver, A. T. Collier, 474,214. Filed June 30, 1891.

Employs two diaphragms, each placed between two magnet poles and having an ear-piece or mouth-piece connected with the air chambers between the diaphragms and the adjacent ends of the inner magnets.

Speaking Telegraph, T. A. Edison, 474,230. Filed April 27, 1877.

Claim 1 follows:

In a speaking telegraph transmitter the combination of a metallic diaphragm and disc of plumbago or equivalent material, the contiguous faces of said disc and diaphragm being in contact.

(*See* THE ELECTRICAL ENGINEER, *May* 11.)

Speaking Telegraph T. A. Edison, 474,231. Filed July 20, 1877.

Claim:

In a telegraphic apparatus operated by sound the combination with the diaphragm of one or more contact points of plumbago or similar inferior conductor in the electric circuit whereby the rise and fall of electric tension is proportionate to the pressure exerted upon the said point or points by the diaphragm.

(*See* THE ELECTRICAL ENGINEER, *May*, 11.

Speaking Telegraph, T. A. Edison, 474,232. Filed Feb. 18, 1886.

Claim:

A spring forming or carrying one electrode of the circuit of a telephone and constantly pressing against the other electrode and diaphragm to maintain the required initial pressure between the electrodes and yield to the movement of the diaphragm,

(*See* THE ELECTRICAL ENGINEER, *May*, 11.)

Telephone-Circuit, H. V. Hayes, 474,323. Filed Jan. 13, 1892.

Two telephone circuits each extending from a sub-station to the same central station and closed through a section of conductor common to both and including a battery having an induction coil interposed between it and one of the conductors of the said circuit, the two helices being included in the two circuits respectively.

ON THE THEORY OF THE AUTOMATIC CONTACT-BREAKER.[1]

BY V. DVOŘÁK.

THE author points out that in the original theory of the spring cut-out (the inaccuracy of which was indicated by Koppe) the effect of the electromagnet on the keeper, during the return to the original position, is entirely overlooked, and its attraction is only considered when the keeper is in the position of rest. Since the effects of the actual attractions referred to must be equal and opposite, they can contribute nothing towards the maintenance of the vibrations, supposing that we neglect other important circumstances. The other ways in which the vibrations of the hammer can be affected will now be investigated. They include the retardation of contact, self-induction, the influence of the iron, the dimensions of the core and hysteresis. A complete theory of Wagner's hammer can then be constructed. The curve formed by the increasing current on making contact can be represented by two incomplete sine curves differing by $T/4$ in phase. The first represents the force which is proportional to the distance from the position of equilibrum, and is in operation only during the movement of the keeper from this position up to the magnet and back again, that is during half a vibration. It can have no influence on the maintenance of the vibration which is kept up by the second curve differing in phase by $T/4$. It is this, therefore, that has to be attended to in the winding in order to make the amplitude of the vibration as great as possible. With a specially constructed Wagner-Elsass hammer, which depended on the torsional vibration of an elastic wire, an approximate determination of the energy necessary to maintain the vibrations was arrived at. The result proved that such a hammer must be regarded as an extremely inefficient motor, as approximately only about 1 per cent. of the energy was applied in maintaining the vibrations.

The most important conclusions are as follows : Owing to the small amount of energy requisite for maintaining the vibrations, the resistance of the cells must be kept quite low. Also the resistance of the magnets must not be too great, as this does not conduce to reliability and powerful action of the bell. As to whether the design could be best improved by the use of a shunt or an extra current circuit (in large bells) or a closed secondary coil, the author does not decide. If the circuit-breaker is to be made specially powerful (*e. g.*, for acoustic purposes), the former means can be used with advantage; in particular, the ratio of the coefficient of self-induction to the total resistance must be given a suitable value, and this must be considered in determining the number of ampere turns.
